

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE NEW AMERICAN CYCLOPÆDIA.

FUGGER

FUGGER, the name of a German family of wealthy merchants. Its founder was **JOHANNES**, a weaver of Graben, near Augsburg, who lived in the first half of the 14th century, and acquired a large property in lands by commerce in cloths. His son, of the same name, continued the occupation of weaver, to which he also added that of cloth merchant, and obtained by marriage the right of citizenship in Augsburg. **ANDREAS**, eldest son of the latter, lived about 1400, and was known as "Fugger the Rich." The nephews of the last, **ULRICH**, **GEORG**, and **JAKOB**, born about the middle of the 15th century, covered the Baltic with their commerce, which extended also to Hungary, Italy, and even to India, were able to influence the affairs of the empire by lending money to the princes, married into the most illustrious families, and were ennobled by the emperor Maximilian I. After attaining to high political dignities, they continued their commerce, built in the Tyrol the splendid castle of Fuggeran, greatly embellished the city of Augsburg, and found a new source of wealth by working the mines of Innthal, Falkenstein, and Schwartz. The only heirs of these 3 brothers were the 2 sons of Ulrich, **RAMUND**, born in 1489, died in 1535, and **ANTON**, born in 1498, died in 1560. The former of these patronized letters and the sciences, and was saluted in many poor poems as the Mæcenas of his times. The latter raised the family to its highest degree of power and prosperity. The emperor Charles V. resorted to them both when pressed for money, yielded to them the privilege of coining, made them counts and princes of the empire, and was lodged in the splendid mansion of Anton when he attended the diet of Augsburg. They established at Augsburg a cabinet of antiquities, a gallery of paintings, and a botanical garden, built the church of Saint Maurice, paid 8,000 crowns to Titian for a few paintings, and collected the 2 largest libraries that had yet been seen in Germany. Their name was given to a street in Madrid, and "as rich as a Fugger" became a proverb. Upon the death of these 2 brothers the family divided into numerous lines, and its most important branches at present are the princely houses of Kirchberg and Babenhausen.

FUGITIVE, literally, one who flies away.

FUGITIVE

At common law there was the fugitive from justice; and the name of fugitive was also given sometimes to a person escaping from arrest or imprisonment for debt or from apprenticeship; and in the feudal law an escaping serf or bondsmen was regarded as a fugitive. In the United States the name is commonly given to one who, in the words of the federal constitution, is "held to service or labor in one state under the laws thereof," and "escapes into another;" that is, a fugitive slave. A fugitive from justice is more exactly defined as one who, having committed a crime within one jurisdiction, escapes from punishment by fleeing into another. The law of nations certainly does not permit the sovereignty from which the fugitive has escaped to enter, *proprio vigore*, into the country where he has taken refuge, and seizing him there, take him home for punishment. Of this there is no question whatever. But it has been much discussed whether the law of nations requires the arrest of the fugitive in the territory to which he flies by the authorities thereof, and the delivering or extradition of him to the authorities from whom he has fled. The weight of authority is, perhaps, against any such obligation or duty in the absence of treaty stipulations. But such treaties have been frequently made of late years, and are justly regarded as the effect and indication of advancing civilization. The American government has made treaties providing for the extradition of fugitives from justice with England, France, Bavaria, Prussia, Hanover, and other states of the German confederation. These treaties usually specify the crimes which fugitives must be accused of to be delivered up; and also provide that no country shall be required to deliver its own citizens or subjects to a foreign country for trial and punishment.—As between the states of the American Union, extradition is made compulsory by the federal constitution, art. iv., sec. 2, which provides that "a person charged in any state with treason, felony, or other crime, who shall flee from justice, and be found in another state, shall, on demand of the executive authority of the same state from which he fled, be delivered up to be removed to the state having jurisdiction of the crime." In the several states there

are statutory provisions or established usages regulating the procedure in such cases. They vary in some respects, but the process is substantially as follows everywhere: 1. The alleged fugitive is charged with the crime in the state from which he flies, and sufficient evidence of his probable guilt is offered to the executive. 2. That executive gives to the applicant a formal requisition (reciting generally the facts of the case) upon the executive of the state to which he has fled. 3. This last executive then examines into the case, usually by the prosecuting officer of the state, as far as he deems necessary, and if he sees no sufficient reason to the contrary, issues his warrant to some proper officer. 4. Thereupon this officer takes possession of the fugitive, and is protected in carrying him to the state from which the requisition issues, and there surrendering him to the proper officer. 5. It has been held that if the executive which issues the warrant becomes satisfied that it should not have been issued, it may withdraw it and liberate the fugitive at any time before he passes beyond the limits of the state. The extradition of the fugitive from service is provided for, not by state statutes, but by acts of congress. They provide very summary processes, as entirely ministerial and as little judicial as such processes can be, in the state to which the fugitive slave has fled, resting the whole procedure upon a previous judicial investigation at home, which has been held to be conclusive as to the service due and the escape, and to leave for trial in the foreign state only the question of personal identity. If the fugitive slave be surrendered to the claimant, and if the claimant takes him home, he may there have all the opportunity which the general law gives him of trying the question whether he is bound to service. This statute and process have been held to be applicable to fugitive apprentices.

FUGUE (Lat. *fuga*, flight), a species of musical composition in which one voice or part seems to be perpetually flying away from another, whence the name. The principal musical thought of the piece, or the subject, having been performed by one voice or part, is taken up by another, and so on with all the voices or parts, each commencing after the others, and all performing together. The result is an endless pursuit and flight of the same theme by the different parts. Fugues are simple, double, or counter, the latter being much the most complicated, and afford a wide field for invention, of which the older composers frequently took advantage.

FULDA, a S. E. province of Hesse-Cassel, bounded E., S., and W. by Weimar, Bavaria, and Hesse-Darmstadt; area, 860 sq. m.; pop. in 1854, 138,685.—**FULDA**, the capital of the province, is situated on a river of the same name, here crossed by 3 bridges, 56 m. N. E. from Frankfort-on-the-Main; pop. 9,570. It contains an electoral palace and gardens, formerly the residence of the prince-bishops, 11 churches, 2 convents, an ecclesiastical seminary, and a num-

ber of schools. The cathedral is a fine modern building, the 4th which has stood on this site. Of the ancient church it retains only a crypt, in which is the sarcophagus of St. Boniface. Fulda has also a library of 50,000 volumes, manufactories of cotton, linen, and woollen goods, &c., and trade in corn and cattle.

FULGURITE (Lat. *fulgur*, lightning), sand vitrified into a slender tube, which is sometimes of great length, found on sandy beaches and plains, penetrating in some instances 50 feet or more beneath the surface, and dividing into several branches. Beudant describes fulgurites under the mineral species quartz, by the name of *quartz tubuleux*, and ascribes their origin to a stroke of lightning. Their diameter varies from $\frac{1}{8}$ of an inch to $8\frac{1}{2}$ inches, and the thickness of the wall of the tube from $\frac{1}{16}$ of an inch to 1 inch. Their inner surface is vitrified; the outer is composed of grains of sand cemented together. M. Fiedler exhibited one to the French academy of sciences in 1843, which he excavated from a point in a vineyard which had just been struck by lightning. Dufrenoy (*Mineralogie*, vol. ii., p. 161) speaks of one he saw in possession of M. Fictor, which was more than 10 metres long, and presented beside many ramifications. An account of a remarkable one dug up at Rome, N. Y., was published in the "American Journal of Science" (vol. xiv. p. 220, 1848). M. Hachette, together with Messrs. Savart and Beudant, succeeded in producing some artificially, making use of a strong electrical battery, and causing the charge to pass through a quantity of pounded glass placed in a hole in a brick. One was an inch in length, and from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch in diameter outside—inside only $\frac{1}{16}$ of an inch. With a little chloride of sodium mixed with the glass, a tube was obtained of uniform diameter $1\frac{1}{2}$ inches long.

FULLER, ANDREW, an English Baptist theologian, born in Wicken, Cambridgeshire, Feb. 6, 1754, died in Kettering, Northamptonshire, May 7, 1815. Till the age of 20 he was chiefly engaged in husbandry; but having united himself to the Baptist church he became a preacher of that denomination, and was settled first at Soham in 1775, and afterward at Kettering in 1788. In 1784 he published a treatise entitled "The Gospel Worthy of all Acceptation," a work of great ability, which excited much controversy, and is believed to have materially modified the prevailing doctrinal views of the denomination to which he belonged. In 1799 he composed his "Dialogues and Letters" (published collectively in 1806). In 1792 he took an active part with Carey and others in establishing the Baptist missionary society, and was appointed its first secretary; and from that time till the close of his life he was constantly engaged in the most important and arduous labors for its prosperity, and the extension and success of its missions. In 1794 he published "The Calvinistic and Socinian Systems, examined and compared as to their Moral Tendency;" in reply to which Dr. Joshua Toulmin wrote "The

Practical Efficacy of the Unitarian Doctrine considered," and Fuller rejoined in "Socinianism Indefensible, on the ground of its Moral Tendency" (1797). He was the author of a great number of other treatises, sermons, &c., all of which bear the marks of an acute and powerful mind. His "Complete Works" were published in 8 vols. 8vo. (London, 1824), and in 1 vol. imperial 8vo., with a memoir by his son (1852). They have been reprinted in the United States with a memoir by the Rev. Joseph Belcher (8 vols. 8vo., Philadelphia), and in other editions. The degree of D.D. was conferred on Mr. Fuller by Yale college, and also by the college of New Jersey, but he declined receiving it as unscriptural and incompatible with the simplicity of the Christian character. From his sagacity and strong common sense, his almost instinctive knowledge of the human heart, and the native vigor and practical character of his mind, he has been called "the Franklin of theology."

FULLER, MARGARET. See OSSOLI, MARGARET FULLER.

FULLER, RICHARD, D.D., an American clergyman, born in Beaufort, S. C., in 1808. He was graduated at Harvard college in 1824, subsequently studied law, and before his 21st year was admitted to the bar of South Carolina. He almost immediately entered upon a large and lucrative practice, and was on the road to professional eminence when he was prostrated by a fit of sickness. On his recovery he became a member of the Episcopal church, afterward joined the Baptist denomination, and, renouncing his profession, studied for the ministry. He was ordained in 1833, and took charge of the Beaufort Baptist church, where his preaching and pastoral offices were attended with beneficial results. In 1847 he assumed the charge of the 7th Baptist church in Baltimore, one of the largest in the city, with which he still remains connected. Among Dr. Fuller's published writings are: "Correspondence with Bishop England concerning the Roman Chancery;" "Correspondence with Dr. Wayland on Domestic Slavery;" "Sermons," and "Letters."

FULLER, THOMAS, one of the wittiest and most peculiar and original of English authors, born in Aldwinckle, Northamptonshire, in June, 1608, died Aug. 15, 1661. He was carefully educated by his father, the rector of St. Peter's in his native village, till in his 18th year he was sent to Queen's college, Cambridge. He won the highest university honors, and received the degree of bachelor in 1625, of master in 1628, a fellowship in Sidney Sussex college in 1631, and about the same time the living of St. Bonet's, Cambridge, where he exhibited great eloquence as a preacher. He was also made a prebendary of Salisbury. His first publication was a poem entitled "David's heinous Sinne, heartie Repentance, heavey Punishment" (London, 1631). He was soon after presented to the rectory of Broad Windsor, Dorsetshire, where he prosecuted several

works that he had planned at Cambridge. After 7 years he removed to London, where his fame for pulpit eloquence secured for him the lectureship of the Savoy, and he published his "Historie of the Holy Warre" (Cambridge, 1639; 5th ed., 1651), which greatly extended his reputation. In 1640 he was member of the convocation assembled in Henry VII.'s chapel, Westminster, to make canons for the better government of the church, and has given an interesting account of its proceedings in his "Church History." On the outbreak of the civil war he remained in London after the departure of the king, laboring to mitigate the violent feelings that were dividing the people into two hostile parties; and in 1643, on the anniversary of the accession of Charles, he preached a sermon in Westminster abbey of so loyal a spirit as to give great offence to the parliamentarians. He soon after declined taking the oath to parliament, and joined the king at Oxford, who was curious concerning his extraordinary abilities, and immediately invited him to preach before him; but his calm moderation pleased the royalists as little as it did their opponents. He resided at Oxford in Lincoln college, but sentence of sequestration was pronounced against him, and he lost his books and manuscripts. Two royalist noblemen gave him the remains of their private libraries that had escaped the ravages of war, and he at length identified himself with the royal cause by seeking a chaplaincy in the army under Sir Ralph Hopton. He improved the leisure which this position gave him, and the facilities presented by the marches and countermarches through the country, in collecting by an extensive correspondence and personal inquiries the materials for his "Worthies of England." He was besieged at Basing House in 1644 with a small party of royalists, but animated the garrison to so vigorous a defence that the parliamentary commander was obliged to retire with considerable loss. Taking refuge in Exeter on the defeat of Hopton in 1645, he preached constantly to the citizens till its surrender in April, 1646, and published there his "Good Thoughts in Bad Times" (1645). His "Good Thoughts in Worse Times" appeared in 1646, after his return to London, and he published a new edition with the "Second Century of Good Thoughts in Bad Times" (1647); in 1660 he completed the series with "Mixt Contemplations in Better Times." He continued to preach and to publish tracts and sermons, notwithstanding "it had been the pleasure of the present authority to make him mute," and notwithstanding Cromwell's prohibition of all persons from preaching or teaching schools who had been adherents of the late king. In 1648 he became rector of Waltham abbey in Essex, and in 1658 chaplain to Lord Berkeley and rector of Cranford. Shortly before the restoration he was reinstated in his lectureship at the Savoy, and after that event was chosen chaplain extraordinary to the king, and regained the prebend of Salisbury. A

bishopric was expected for him, when he met his death by a fever. He was buried in his church at Oranford, in the chancel of which his monument still remains. His "Holy and Profane State, a collection of Characters, Moral Essays, and Lives, Ancient, Foreign, and Domestic" (Cambridge, 1642; 4th ed. 1668), proposing examples for our imitation and abhorrence, is one of his best productions, and fully exhibits his sagacity of thought and pithiness of style. His "Church History of Britain, from the Birth of Jesus Christ until the year MDCXLVIII." (London, 1655), though abounding in jokes, quibbles, dedications, anecdotes, and curious and irrelevant learning, is one of the most remarkable works in the language for wit, piety, pathos, and imagination, and contains many interesting memorials, the result of long, active, and extended research. The "History of the Worthies of England," a collection of eccentric biographies, published posthumously (London, 1662), has been more generally read than any other of his works, and abounds in gossip, admirably told stories, curious details, and witty and excellent reflections. The men whose lives are recorded are arranged according to their native counties, of which he mentions the natural productions, herbs, medicinal waters, curiosities, local proverbs, manufactures, and buildings. Of his minor productions, the principal are the "Appeal of Injured Innocence" (London, 1659), a defence of his "Church History" (with which it is sometimes bound) against Heylin, and treating almost every subject within the range of human disquisition; the "Pisgah-Sight of Palestine" (London, 1650); and "Andronicus, or the Unfortunate Politician" (London, 1646). The style of all his writings is extremely quaint and idiomatic, in short and simple sentences, and singularly free from the learned pedantry of his time. "Next to Shakespeare," says Coleridge, "I am not certain whether Thomas Fuller, beyond all other writers, does not excite in me the sense and emulation of the marvellous; the degree in which any given faculty, or combination of faculties, is possessed and manifested, so far surpassing what we would have thought possible in a single mind, as to give one's admiration the flavor and quality of wonder. Fuller was incomparably the most sensible, the least prejudiced great man, in an age that boasted of a galaxy of great men. In all his numerous volumes on so many different subjects, it is scarcely too much to say that you will hardly find a page in which some one sentence out of every three does not deserve to be quoted by itself as a motto or as a maxim." His memory was so remarkable, that he could repeat a sermon verbatim after hearing it once, and 500 unrelated words of different languages after hearing them twice. His lively and learned conversation made his company much courted, and he would listen for hours to the prattle of old women in order to catch snatches of local history and tradition and proverbial wisdom.

FULLERS' EARTH, an unctuous sort of clay,

useful in fulling cloth, from its property, common to aluminous earths, of absorbing oil and grease. That variety of clay is preferred which falls to pieces when put in water, making a slight crackling sound. Its colors are various shades of yellowish, greenish, bluish, brown, and gray; lustre dull, but appears greasy when rubbed. Composition as given by Dr. Ure: silica 53, alumina 10, peroxide of iron 9.75, magnesia 1.25, lime 0.5, water 24, potash a trace. Dr. Thomson found silica 44, alumina 23.06, protoxide of iron 2, magnesia 2, lime 4.08, water 24.95. It is not now esteemed of so much value as formerly, soap having taken its place. In England it used to be so highly valued that its exportation was prohibited. It was carried in large quantities from the counties of Surrey and Buckingham, and then sold to be transported to the north or west of England. When used, it was first dried by the sun or by fire, and then thrown into cold water. The powder thus formed was sorted by washing into coarse and fine qualities, the former of which were applied to inferior cloths, the latter to the finer goods.

FULLERTON, LADY GEORGINA CHARLOTTE, an English authoress, born Sept. 28, 1812. She is the daughter of the 1st earl of Granville, and was married in 1838 to Capt. Alexander George Fullerton. Her first publication, a novel entitled "Ellen Middleton," appeared in 1844, and was succeeded within a few years by "Grantley Manor." Both works exhibit constructive skill and an analysis of character of no mean order. "Lady Bird," published in 1852, after the conversion of the authoress to the Roman Catholic church, is one of her most imaginative works.

FULLING, also called MILLING, the operation of removing greasy matters from woollen goods, and of giving to them a more compact texture by causing the fibres to entangle themselves more closely together, as in the process of felting. Fulling mills are ancient inventions, the process probably having been applied to the first woven fabrics, as felting must already have been then known. Cloths brought to the fulling mills contain the oil which was applied to the fibre in weaving. The first process to which they are subjected is called scouring or braying. This is effected by placing the rolls in troughs so arranged that they can retain the detergent liquid, as, first, stale urine and hogs' dung, subsequently urine alone, and again fullers' earth and water, while heavy oaken mallets or pounders slide down with force into one end of the troughs and mash and roll over the folds of cloth. The pounders are lifted by revolving cams, and kept in action for hours together, one to each trough. The oil is absorbed by the clay, and both are washed off by the water. The fulling is properly a second process performed in the same machines with the use of soap applied liberally in solution. The stampers are better made of polished iron, and the operation is facilitated with economy of soap by keeping the trough filled with hot steam. Cloth is also fullled in what is called the fulling machine with-

out stamping, the cloth being pushed in a succession of folds through a low trough, the top of which is made by weights to press upon these folds and resist their progress through. The soap is washed out after the fulling, and the nap is raised by teasing. To properly full a piece of ordinary broadcloth it has been customary to allow from 60 to 65 hours, and 11 lbs. of soap; the shrinkage in width is from 12 quarters to 7, and in length from 54 yards to 40. A piece of Venetian broadcloth 54 yards shrank to 45 yards in length, and from 7 quarters 8 nails to 6 quarters 2 nails in width, and required 12 hours and from 6 to 7 lbs. of soap.

FULMINATES (Lat. *fulmen*, a thunderbolt), salts of fulminic acid and some base, as gold, platinum, silver, and mercury, all of which possess the property of exploding with more or less violence. The last two only are applied to any practical purpose. Fulminating mercury (represented by the formula 2Hg O , Cy , O_2) is the compound used in the manufacture of percussion caps. It is prepared, as recommended by Dr. Ure, by dissolving at a moderate heat 1 ounce weight of mercury in $7\frac{1}{2}$ fluid ounces of nitric acid of specific gravity 1.4, turning this into 10 fluid ounces of alcohol of specific gravity .83, the temperature of the acid and mercury being about 180°F . It is well to employ for dissolving the mercury a glass retort furnished with a receiver of glass, which is kept cool by a current of water. The acid vapors which are condensed in this should be returned to the retort. When the mercury is dissolved, the solution should be slowly introduced into the matrass containing the alcohol, the capacity of which should be at least 6 times that of the liquids. Bubbles of gas soon begin to escape from the bottom of the mixture, and the whole is soon thrown into a rapidly bubbling condition. It becomes frothy and white; highly combustible vapors escape, which should be allowed to pass off into the air without coming in contact with flame or any heated surface. These vapors consist of various products of the oxidation of the alcohol, as aldehyde, acetic acid, formic acid, and nitrous, acetic, and formic ethers. They may be condensed and converted to use in other operations; but any obstruction thus presented to their free escape is regarded as injuriously affecting the main object of the operation. A considerable quantity of them were condensed by Mr. Samuel Guthrie of Sackett's Harbor, N. Y., whose experiments will be noticed hereafter. The effervescence ceasing, the contents of the matrass are turned upon a double filter of paper, and thoroughly washed with pure cold water, till the washings cease to reddan litmus paper. When quite drained, the filter is removed from the funnel, and spread open with its contents upon a plate of copper or stone ware, raised by steam or hot water to the temperature of 212°F . It is thus dried, and may then be put away in paper parcels of 100 grains each, which are to be kept protected from moisture. The salt when well prepared is

in small sparkling crystals of brownish gray color, which moistened with water upon a slip of paper appear transparent. They dissolve in 180 times their weight of boiling water, leaving no residuum if pure. As the water cools, the fulminate reappears in pearly spangles. Fulminate of mercury explodes at a heat somewhat below 870°F ., or by being struck smartly between two hard metallic surfaces. Rubbing it between two wooden surfaces will produce the same effect. When moistened with 5 per cent. of water, the portion struck may explode without communicating the effect to the portions in contact. Fulminate of mercury may be fired in contact with gunpowder without igniting this, even when covered loosely with it; but when the powder is packed in a tube and the fulminate in a percussion cap is exploded in contact with it, the gunpowder is more instantaneously ignited throughout than by any other mode of firing. The projectile effect of 10 parts as formerly fired is thus obtained from $8\frac{1}{2}$ parts.—In the manufacture of percussion caps the French use 1 kilogramme of mercury to produce $1\frac{1}{2}$ kilogrammes of fulminate, which is sufficient for 40,000 caps. They grind the mercurial salt with 80 per cent. of water upon a marble table with a wooden muller, mixing 6 parts of gunpowder with 10 of fulminate. This when dried forms the composition which is introduced into the caps—about 1 grain to 4 caps. Dr. Ure recommends a solution of mastic in spirits of turpentine as the fittest medium for attaching the fulminate to the bottoms of the caps. Instead of using the fulminate alone, or with gunpowder, as practised by the French, the English mix with every 3 parts of it 5 parts of chlorate of potash, 1 part of sulphur, and 1 of powdered glass. Nitre is also recommended in the proportion of $\frac{1}{3}$ of the fulminate, mixed with it when it contains 20 per cent. of water. Mr. Samuel Guthrie of Sackett's Harbor, N. Y., who performed a series of practical experiments on a large scale upon these compounds, found that a most efficient preparation was made by mixing 1 part of oxide of tin with 3 parts of fulminating mercury, and grinding them together with a stiff solution of starch. The starch gave cohesiveness to the grain without injuring its explosive qualities. Mr. Guthrie's experiments are recorded in the "American Journal of Science" for Jan. 1882. They are highly interesting for their practical character and applications, and the extreme hazard which attended them. It was in the course of these experiments that Mr. Guthrie made the discovery of chloroform, also discovered about the same time in France and Germany. The original fulminating powder, patented by the Rev. Mr. Forsyth in 1807, consisted only of chlorate of potash, sulphur, and charcoal. In the manufacture of percussion caps a drop of gum is introduced into the bottom of each one, and the fulminating powder is dropped in upon this. A coating of varnish is sometimes afterward applied to protect them from moisture. It was represented by an exhibitor at the Lon-

don exhibition in 1851, that 1,800,000,000 caps were manufactured yearly for sporting guns in Europe, which involved a consumption of 896,000 lbs. of copper.—Fulminating silver (2Ag O , Cy_2O_3) is prepared like fulminating mercury, except that the mercury is replaced by fine silver, and the nitric acid solution is allowed to become cool before it is turned into the alcohol. Or it may be made by introducing finely pulverized nitrate of silver into concentrated alcohol contained in a matrass, and after shaking it well adding as much fuming nitric acid as there was alcohol. On boiling, the nitrate of silver is first dissolved, then decomposed, and a flocculent precipitate separates, which is formed of an agglomeration of little needles of fulminate of silver. When this ceases to form, water is added, and the mixture is filtered, the washing being continued till there is no further acid reaction. The precipitate is then cautiously dried. This compound is so extremely dangerous that its manufacture ought to be entirely abandoned. It is used only for explosive toys, which are made of little glass balls of the size of peas, into which the fulminate is introduced in a moist state and dried. They are enveloped in a bit of blotting paper, and when used are exploded by throwing them upon the ground. Mr. Guthrie mentions his having suffered severely from explosions in his experiments; and in 1882 Dr. Robert Haré was dangerously injured by the explosion of a quantity of the feathery fulminate, which was nearly enough to fill an ounce bottle. It ignited as he was in the act of pouring it out upon the face of a hammer, as he had frequently done before. The explosion could be accounted for only on the supposition that a particle of the powder might have been compressed between the neck of the vial and the face of the hammer. Three fingers of his right hand were broken, and his assistant and a pupil were also injured. An English chemist named Hennel is reported to have been not long since killed by the explosion of about half a pound of the fulminate. He was torn in pieces, and his limbs were thrown in different directions. It is recommended never to keep the fulminates in glass vials, but in pasteboard cases, covered loosely with a card. They have been known to explode spontaneously, from no other cause apparently than a jarring motion in the room crowding the particles more closely together. An interesting paper by Prof. William H. Ellet upon the compound of cyanogen, including the fulminating salts, may be found in the "American Journal of Science" for July, 1830.—A compound is described as fulminating powder, into the composition of which fulminic acid does not enter. It is a mixture of 3 parts of nitre, 2 of dry carbonate of potash, and 1 of sulphur, the materials to be ground together in a warm mortar. If placed on a shovel over a fire, the compound melts at a temperature of about 330° and violently explodes. Another similar explosive mixture consists of 1 part of yellow prussiate of potash, 2 of chlorate of potash,

and 1 of sugar well dried, the whole to be ground and then intimately mixed.

FULMINIC ACID, one of the isomeric modifications of cyanic acid, represented by the formula Cy_2O_3 , 2HO . Its compounds are distinguished for their explosive character, in which they differ from those of cyanic acid. All attempts to obtain it in an isolated condition have failed from its tendency to instantaneous decomposition with explosion.

FULTON, the name of counties in several of the United States. I. An E. co. of New York, drained by Sacandaga river and E. Canada creek; area, about 530 sq. m.; pop. in 1855, 23,284. The soil is fertile and the surface uneven, with several mountainous elevations. The productions in 1855 were 33,908 tons of hay, 11,145 bushels of wheat, 855,855 of oats, 155,738 of Indian corn, 182,964 of potatoes, and 840,897 lbs. of butter. There were 9 grist mills, 3 paper mills, 90 saw mills, 2 woollen factories, 25 tanneries, 1 brick yard, 5 lime factories, 2 newspaper offices, 109 school houses, and 39 churches. Assessed value of real estate in 1856, \$3,862,000. The N. Y. central railroad passes near the S. boundary of the county. Formed from Montgomery co. in 1838, and named in honor of Robert Fulton. Capital, Johnstown. II. A S. co. of Penn., bordering on Maryland, and drained by Conoloway and Licking creeks, tributaries of the Potomac; area, 380 sq. m.; pop. in 1850, 7,567. Its E. boundary is formed by Cove mountain; Siding hill lies on its W. frontier, and between the two are fertile valleys. The uplands produce timber, which forms one of the chief staples. Tan bark, hay, and grain are also exported. The productions in 1850 were 88,758 bushels of wheat, 50,885 of Indian corn, 49,075 of oats, 4,752 tons of hay, 100,260 lbs. of butter, and 18,094 of wool. There were 18 corn and flour mills, 5 saw mills, 3 wool-carding mills, 10 tanneries, 1 newspaper office, 20 churches, and 1,570 pupils attending public schools. The county was formed from Bedford co. in 1848. Capital, McConnellsburg. III. A N. co. of Ark., bordering on Missouri, and drained by the N. fork of White river; area, 860 sq. m.; pop. in 1854, 2,269, of whom 65 were slaves. It has a hilly surface and a good soil, suitable for grain and pasturage. The productions in 1854 were 52,071 bushels of Indian corn, 3,667 of wheat, 11,538 of oats, and 30 bales of cotton. Capital, Pilot Hill. IV. A S. W. co. of Ky., bounded S. by Tennessee, and separated from Missouri on the W. and N. W. by the Mississippi river; area, about 200 sq. m.; pop. in 1850, 4,446, of whom 943 were slaves. The surface is somewhat diversified, and the soil generally fertile. The principal exports are tobacco, grain, and live stock. The productions in 1850 were 236,315 bushels of Indian corn, 25,494 of oats, 222,482 lbs. of tobacco, and 4,209 of wool. There were 2 grist mills, 1 saw mill, 1 tannery, 1 newspaper office, 7 churches, and 278 pupils attending public and other schools. The county

is traversed by the Mobile and Ohio railroad. Capital, Hickman. Taken from Hickman co. in 1845. V. A N. W. co. of Ohio, bordering on Michigan, drained by Tiffin's river, a branch of the Maumee; area, about 337 sq. m.; pop. in 1850, 7,781. It has an undulating surface and a fertile soil, suitable for grain and pasture. The productions in 1850 were 81,847 bushels of wheat, 136,810 of Indian corn, 58,735 of oats, 10,490 tons of hay, and 153,404 lbs. of butter. There were 2 flour mills, 12 saw mills, and 5 churches. The county is traversed by the northern Indiana air line railroad from Toledo to Chicago. Capital, Ottoskee. VI. A N. co. of Ind., drained by Tippecanoe river; area, 346 sq. m.; pop. in 1850, 5,982. It has a level surface, occupied partly by prairies, partly by oak openings, and partly by forests. Iron is found in some localities, and the streams furnish abundant water power. The soil is mostly of good quality, suitable for grain. In 1850 it produced 221,761 bushels of Indian corn, 70,757 of wheat, 32,843 of oats, and 4,637 tons of hay. The county contained 11 churches, and 1,300 pupils attending public schools. Organized in 1836. Capital, Rochester. VII. A W. co. of Ill., bounded S. E. by the Illinois river, and drained by Spoon river; area, 870 sq. m.; pop. in 1855, 27,968; in 1858, about 30,000. The Illinois river, which is here navigable, is the channel of a large export trade. Spoon river is valuable for water power, and nearly all the streams are bordered by a good growth of timber. The soil of the county is rich and well cultivated; the surface is undulating, and occupied partly by prairies, partly by woodlands. Coal is found in abundance. The productions in 1850 were 1,430,717 bushels of Indian corn, 274,479 of wheat, 178,784 of oats, 33,791 lbs. of wool, and 302,029 of butter. In 1858 there were 40 churches, several newspaper offices, and over 4,000 pupils attending public schools. The Peoria and Oquawka railroad runs near the northern boundary, and another line has been projected which will intersect the county E. and W., connecting the Mississippi and Illinois rivers. Capital, Lewistown.

FULTON. I. A post town of Hamilton co., Ohio; pop. in 1850, 3,224. It is a suburb of Cincinnati, and is situated just above that city on the Ohio river, having a water front of about 2½ m., and extending back a few hundred yards to a ridge of lofty hills from which is obtained a great quantity of excellent limestone. The principal business of the place is steamboat building. Beside numerous boat yards, steam saw mills, lumber yards, &c., it contains a dry dock, a rolling mill, and several churches. II. A post village and the capital of Callaway co., Mo., 12 m. from the Missouri river, and 20 m. N. E. of Jefferson City; pop. in 1850, about 500. It is extensively engaged in the manufacture of earthenware, and contains a newspaper office, several churches and academies, an asylum for the deaf and dumb, and the state lunatic asylum. The last is a beautiful edifice, 5

stories high and 210 feet long, established in 1848 on a plot of 460 acres given together with \$12,000 by the people of the county.

FULTON, ROBERT, an American inventor and civil engineer, celebrated for the successful introduction of steam navigation, of Irish descent, born at Little Britain, Lancaster co., Penn., in 1765, died in New York, Feb. 24, 1815. When about 3 years old he lost his father. He received a common school education, went to Philadelphia at the age of 17, and his name appears in the directory of that city for 1785 as that of a miniature painter. Mechanical pursuits, however, even in his youth mingled with those of the artist. Before attaining his majority he had laid by a sum sufficient to buy a small farm in Washington co. He placed his mother in possession of his new purchase, and soon afterward met gentlemen who were attracted by his talent and advised him to go to England and place himself under the tuition of Benjamin West. Following this advice, he met with a very kind reception from West, of whose home he remained an inmate for several years. On leaving his family, Fulton commenced a tour for the purpose of examining the treasures of art scattered through the country residences of the English nobility, and remained for two years in Devonshire, where he made the acquaintance of the duke of Bridgewater, the founder of the canal system of Great Britain, at whose instance, it has been said, Fulton abandoned the profession of a painter and adopted that of a civil engineer. He was employed at Birmingham about 18 months, probably in some subordinate capacity upon the canal then in progress in that vicinity. With Earl Stanhope he had an earlier and more intimate acquaintance. This nobleman was a mechanical projector of no inconsiderable pretensions, and at this time was engaged on a scheme of steam navigation by a propeller modelled on the foot of a water fowl. Fulton addressed him a letter in 1798 in which he stated the objections to this plan, and suggested some of the views which he afterward reduced to practice on the Hudson. At Birmingham he was brought into communication with Watt, who had just succeeded in his great improvement of the steam engine, with the structure of which Fulton made himself entirely familiar. During his residence here he devised an improved mill for sawing marble, for which he received a vote of thanks and an honorary medal from the British society for the promotion of arts and commerce. To this period also are referred his patented machines for spinning flax and for making ropes, and the invention of an excavator for scooping out the channels of canals and aqueducts. In 1795 he contributed some essays on the subject of canals to the London "Morning Star," and in the spring of 1796 published in London his treatise on the improvement of canal navigation. His views on the subject did not prove to be of any practical utility. With this treatise he published a

letter to the governor of his native state, pointing out the advantages of canals over turnpike roads; and sent a copy of the work to President Washington, who returned him a flattering acknowledgment. Having obtained a patent in England for canal improvements, Fulton went to France with the view of introducing them there, but his attention was soon diverted to other objects. In 1797 he took up his residence at Paris with Mr. Joel Barlow, with whom he formed a most intimate friendship, which continued through life. With Mr. Barlow he remained 7 years, during which he devoted himself to the study of the modern languages, and the sciences connected with his profession. At this time he devised the submarine boat, afterward styled a nautilus, connected with which were machines, then called submarine bombs, afterward known as torpedoes. This invention he offered several times to the French government, and once to the Dutch ambassador at Paris, without exciting their favorable attention. Negotiations were subsequently opened with him by the British government, which induced him to visit London in May, 1804. Here he had interviews with Mr. Pitt and Lord Melville, and explained to them the nature of his invention. Mr. Pitt was polite enough to say that if introduced into practice the torpedo could not fail to annihilate all military marines, but Lord Melville condemned the nautilus without a moment's consideration. In June a commission was appointed to examine Mr. Fulton's projects, at the head of which was Sir Joseph Banks. Many weeks elapsed before they gave any attention to the subject, and they then reported the submarine boat as impracticable. In Oct. 1805, he was permitted to experiment on a Danish brig of 200 tons burden with a carcass of 170 lbs. of powder. In 15 minutes from the application of the carcass the explosion took place; the brig, according to Fulton's account, making no more resistance than a bag of feathers, and going to pieces like a shattered egg shell. Notwithstanding this success, Fulton was disappointed in his hopes of government patronage, and at length embarked for his native country. Previous to leaving France, Fulton had superintended the execution of the plates of the splendid edition of the "Columbiad," printed in Philadelphia in 1807, expending on it some \$5,000; whence he derived a pecuniary interest in the work, which he relinquished by will to the widow of Mr. Barlow. The original paintings from which these plates were executed formed a part of the valuable collection he left to his family. On his return he brought with him a family piece representing Mr. West and his wife, and a portrait of himself, all from the pencil of that celebrated artist, with his "Ophelia" and "King Lear," which Fulton had purchased at a sale by the royal academy in 1805. In Dec. 1806, he arrived in New York, and immediately devoted himself to the development and introduction of his plans for sub-

marine war and steam navigation. In the month after landing he went to Washington with his models and drawings, which he explained to the heads of departments, and made a favorable impression. A certain expenditure was authorized by the government to prosecute the experiments with his torpedoes. The probability of a rupture with England, consequent on the affair of the *Leopard* and *Chesapeake*, made the summer of 1807 propitious to the patronage of his project, and on July 20 he "decomposed" a large hulk brig in the harbor of New York with a torpedo containing 70 lbs. of powder. In 1810 he again visited Washington, and at Kalorama, the seat of his friend Barlow, explained some improvements in his plans to Mr. Jefferson, Mr. Madison, and a number of members of congress assembled on his invitation. So successful was he in his explanations that congress at once appropriated \$5,000 for further experiments, to be prosecuted under the direction of the navy department. In the months of Sept. and Oct. commissioners appointed by the secretary met several times in the harbor of New York to report on Fulton's experiments. The sloop of war *Argus* had been prepared to defend herself against them under the orders of Commodore Rodgers, and the result was that she was so ingeniously defended that all Fulton's means of attack proved unavailing. Various reports were made by the commissioners, but Commodore Rodgers did not hesitate to decide peremptorily against Mr. Fulton's system, and to pronounce every part of it wholly impracticable. Fulton continued to believe in it, but on the conclusion of these experiments found himself too fully occupied with other pursuits to renew them. At an early period Fulton's attention had been turned to steam navigation. In Sept. 1798, he had addressed a letter to Earl Stanhope, proposing to communicate to him the principle of an invention "respecting the moving of ships by the means of steam." While domiciliated with Barlow at Paris he formed the acquaintance of Chancellor Livingston, then U. S. minister to France. Livingston had previously been connected with Nicholas Roosevelt and John Stevens in steamboat experiments at home. He now entered into the views of Fulton as they had been explained to Stanhope, and at once offered to provide the necessary funds for an experiment, and to contract for the introduction of the new method, if successful, into the United States. In 1798 an act was passed by the legislature of New York, repealing the act of 1787 in favor of John Fitch, and transferring to Mr. Livingston the exclusive privilege of navigating the waters of the state by steam, on condition that he should within a twelvemonth give proof of his having built a boat of 20 tons capable of a mean progress in Hudson river of 4 miles an hour, and at no time omit for one year to have a boat of this construction plying between Albany and New York. This act was from time to time continued, and Fulton was

finally included within its provisions. Meanwhile his experiments had been going on in France, particularly at Plombières, in the summer of 1802. Late in 1803 Fulton constructed a working model of his intended boat, and at the same time commenced building a vessel 66 feet in length and 8 feet in width. When finished, it did not move with the speed that was expected. In the same year, however, he sent an order to Watt and Boulton for a steam engine to propel a boat of large size, which was completed and reached New York in 1806. Eminently practical and sagacious, Fulton had meanwhile informed himself of every thing that had been attempted in steam navigation in Europe and the United States. His object was success, and there is no reason to believe that he would peril it by omitting to learn the cause of prior failures. He planned for the new machinery a boat that was completed and fitted in 1807 and named *Clermont*. Its progress through the waters of the Hudson is stated at 5 miles an hour. In the course of the ensuing winter it was enlarged to a boat of 140 feet keel and 16½ feet beam. So completely was the utility of the invention established that the legislature contracted to extend the exclusive privilege of Mr. Livingston and Mr. Fulton 5 years for every additional boat, provided the whole term should not exceed 30 years. His second large boat on the Hudson was the *Oar of Neptune*, built in 1807. In the following year the legislature passed another act, confirmatory of the prior grants, and giving new remedies to the grantees for any invasion of them, and subjecting to forfeiture any vessel propelled by steam which should enter the waters of the state without their license. In 1809 Fulton obtained his first patent from the United States; and in 1811 he took out a second patent for some improvement in his boats and machinery. His patents were limited to the simple means of adapting paddle wheels to the axle of the crank of Watt's engine. Meanwhile the power of the legislature to grant the steamboat monopoly was denied, and a company was formed at Albany to establish another line of steam passage boats on the Hudson, between that city and New York. The state grantees filed a bill in equity, and prayed for an injunction, which was refused by Chancellor Lansing on the ground that the act of the state legislature was repugnant to the constitution of the United States and against common right. This decree was unanimously reversed by the court of errors, and a compromise was effected with the Albany company by an assignment to them of a right to employ steam on the waters of Lake Champlain. Legislative aid was in the meanwhile again invoked, and an act was passed directing peremptorily the allowance of an injunction on the prayer of the state grantees, and the seizure of any hostile boat at the commencement of the suit. Litigation was thus effectually arrested in New York, though by an arbitrary and unconstitutional enactment, and the waters of the state remained in the exclusive

possession of Fulton and his partner during the lifetime of the former. A similar controversy with Col. Aaron Ogden of New Jersey was compromised by advantageous concessions, which converted the opponent of the monopoly into its firmest friend, and left him some years afterward the defeated party in the famous suit of Gibbons and Ogden in the supreme court of the United States. Pending these controversies, Fulton constructed ferry boats to run between New York and New Jersey, one for a Brooklyn company, a boat for Long Island sound, 5 for the Hudson river, and several boats for steamboat companies in different parts of the United States, some of them for the Ohio and Mississippi rivers. In 1811 he was made one of the commissioners appointed by the legislature to explore the route of an inland navigation from the Hudson river to the lakes; and in 1814 he addressed a letter to the president of the board illustrating the advantages of the proposed canal. He also joined the other commissioners in their report to the legislature of that year. In the same year he took out a patent for several improvements in the art of maritime warfare. In 1814 congress by law authorized the president to build and employ one or more floating batteries for coast defence, and Fulton was appointed the engineer. He commenced immediately the construction of a war steamer, which was launched within 4 months, and was styled by the constructor the *Demologos*, though it was afterward named *Fulton the First*. This first war steamer was a heavy and unwieldy mass, which obtained a speed against the current of some 2½ miles an hour; but as the pioneer of the steam navies of the world it was regarded as a marvel, and as a most formidable engine of defence. The war having terminated before her completion, she was taken to the navy yard at Brooklyn, where she was used as a receiving ship till June 4, 1829, when she was accidentally blown up. While engaged in the construction of this war steamer, Fulton was employed by the president upon an improved modification of his submarine boat, which was also arrested by his death. Attending as a witness before the legislature of New Jersey in Jan. 1815, on an attempt made by Livingston to procure a repeal of the retaliatory act of that state levelled at the steamboat monopoly, Fulton on his return was exposed for several hours to the inclemency of the weather while crossing the Hudson in an open boat, and contracted a severe illness, which subsequent exposure rendered fatal. His death was recognized as a great public calamity, and beside the usual tributes of respect and regret from corporations and public societies, the members of both houses of the state legislature resolved to wear mourning for some weeks. Fulton was married in 1806 to Miss Harriet Livingston, a relative of the chancellor, by whom he had 4 children. He was of a slender person, above the ordinary stature, with large dark eyes, and features of manly beauty. His success in interesting capital and official influence in the pros-

ecution of his projects indicates the possession of uncommon tact, energy, patience, and enthusiasm. These qualities were aided by the address and manners of a natural gentleman. He was eminently popular in his lifetime, and his name is still regarded with affectionate veneration by his countrymen. In 1846 congress passed an act appropriating \$76,800 in full of the claims of Fulton against the United States for inventing floating steam batteries, superintending the construction of the steam frigate *Fulton*, and for the great benefits conferred on the country by his improvements in the application of steam to navigation.—In Sparks's "American Biography" (1st series, vol. x.) there is a life of Fulton by James Renwick. "The Life of Robert Fulton," by C. D. Colden, 1 vol. 8vo., was published in New York in 1817.

FULVIA, a Roman lady, of the illustrious Fulvian family, born about 80, died about 40 B. C. She was married successively to 3 renowned men, Clodius, Curio, and Mark Antony, and had part in arranging the fearful proscriptions of the 2d triumvirate. When the head of Cicero was brought to her, she pierced the tongue with her needle. To withdraw Antony from Egypt, where the charms of Cleopatra detained him, and to take revenge upon Octavianus, who had affronted her by repudiating his wife, her daughter Clodia, she excited her brother-in-law Lucius Antonius to make war upon Octavianus. The war was unsuccessful, and Fulvia escaped to Greece, was reproached by Antony, who met her at Athens, and died of shame and regret at Sicyon.

FUMIGATION, a method of applying gases and substances reduced to vapor to individuals, infected articles and localities, for medicinal or hygienic purposes. By an inaccuracy of language this name is very generally given to the medicinal agents themselves; strictly speaking, the word bears the same relation to vapors that lotion, bath, and drink bear to liquids. The substances generally used in this manner are water, alcohol, ethers, chlorine, chlorides of the oxides, sulphur, mercurials, the aromatic oily principles of plants, benzoin, camphor, iodine, &c. When directed to the air passages, they are more properly said to be applied by inhalation. When applied to the whole body, fumigations are effected either in common rooms or in apparatus constructed for the purpose, and may be either emollient and soothing, or aromatic and stimulant; in scrofulous and cutaneous diseases iodine and sulphur fumigations are frequently employed in hospitals. When locally applied, they are directed by suitable contrivances to any portion of the body. The necessary vapors are obtained by heat or chemical action; and when the great absorbing power of the skin is taken into consideration, it may easily be believed that its extensive surface may be naturally used for the introduction of most important medicinal agents. Fumigations intended to decompose miasmata, to purify the air of a district or apartments, or to remove infec-

tion from individuals or fomites (*i. e.*, articles liable to retain contagious effluvia), are more properly called disinfectants. Aromatic and odorous substances, like benzoin, camphor, vinegar, and essential oils, vapors of sugar and burned rags, and other domestic fumigations, are not disinfectants, as they do not destroy miasmata, but merely substitute one odor for another; true disinfectants are nitric and chlorohydric acids, chlorides of lime, soda, and potash, which act both upon the infecting substance and upon the mephitic air. Fumigations of nitric acid are obtained by decomposing nitre by sulphuric acid with the aid of heat. The chlorine disinfectant so highly extolled by Guyton de Morveau is made by decomposing common salt and the deutoxide of manganese by sulphuric acid. These 2 fumigations, on account of their irritating properties, can only be applied to rooms and infected articles after the removal of the inhabitants. The chlorides of lime and soda (the latter in the convenient form of Labarraque's solution), and the disengagement of chlorine by burning chloric ether in a fluid lamp, are familiar and effectual ways of fumigating infected rooms and closets, even in the presence of the sick; infected garments may be sprinkled with chlorinated waters, or may be exposed in closed vessels to temperatures even higher than the boiling point of water.

FUNOHAL, a seaport town on the S. E. coast of the island of Madeira, of which it is the capital, in lat. 38° 38' N., long. 16° 54' 30" W.; pop. 20,000. It stands on a wide shallow bay, embraced by the steep promontories of *Punta da Cruz* on the W., and *Cape Garajao* on the E., and enclosed in the rear by broken volcanic ridges. The streets are narrow, winding, and ill paved; there are no public buildings of much elegance, and the numerous churches and convents lack all architectural beauty. The English residents, who number 400 or 500, and other foreigners, have nearly all the trade, which formerly consisted chiefly in exporting wine to England and the British colonies; but the grape crop having utterly failed of late, no wine has been made since 1851, and the rearing of the cochineal insect has been undertaken in place of it. The harbor is indifferent. Fresh meat and poultry are sold at very high prices, but the richest fruits, excellent fish, and vegetables may be had cheaply in abundance. The town is resorted to by invalids on account of its delightful climate. The mean temperature is about 68° F., and the difference between the hottest and coldest months (August and February) averages only 10°.

FUNCTION (*Lat. functio*, performance), in mathematics, a quantity dependent on some other quantity for its value. Thus the height of the tide is a function of the hour of the day, of the moon's age, her declination, the change of her declination, the latitude, the form and position of the coast, the direction and force of the wind, &c. In algebra quantities are functions of each other when their mutual depend-

ence is capable of expression in algebraic forms. Algebraic functions are, in their simplest forms, the sum or difference, the product or quotient, the power or root, the exponent or logarithm, and the trigonometric or circular functions. To these we may add others, but all might by ingenuity be reduced to sum or difference. Very important uses are made of derived functions, functions which are definite functions of other functions. The principal derived function is the differential coefficient, which expresses the rate at which the original function changes for any change in the quantity of which it is a function.

FUNDY, BAY or, an arm of the Atlantic ocean, between the British provinces of New Brunswick and Nova Scotia, about 180 m. long, and from 30 to 50 m. wide. From its mouth, between the S. W. extremity of Nova Scotia and the easternmost point of Maine, its coasts trend N. E. until near its upper extremity it branches into 2 inlets; the N., called Chignecto bay, is about 80 m. long and 8 m. broad; the S. bears the name of Minas channel, and opens into Minas basin in Nova Scotia. At St. John, N. B., situated at the mouth of the river St. John, on the N. coast, the bay is 86 m. wide, and it continues of nearly uniform width from that point to its branching. It is deep, but difficult of navigation. It is remarkable for its extraordinary tides, which rush up from the sea with such rapidity as sometimes to overtake swine feeding on shell fish on the shores, and which rise in Minas basin 40 feet, and in Chignecto channel 60 feet. The bay contains Grand Menan and Long islands, and receives the rivers St. John and St. Croix.

FÜNEN (Dan. *Fyen*), an island of Denmark, having on the N. the Cattegat, W. the Little Belt, and S. and E. the Great Belt and the Binnensee; pop. 176,000. It is the largest of the Danish isles after Seeland, is about 185 m. in circumference, and forms with Langeland a circle of the kingdom. The coast is not very elevated, but is in general rugged and steep, and much indented by bays and arms of the sea. The interior toward the W. is somewhat hilly; in every other direction it is composed of large and fruitful plains, which are well cultivated, and produce abundant crops of corn, the greater part of which is exported. The largest stream in the island is the Odense-æue, which has a course of 36 m. from S. to N., and discharges into the Odensefjord, about 9 m. long, and from 1½ to nearly 5 m. wide. The largest lake is the Arreskov; it is about 9 m. in circuit, and abounds in fish. Fünen is divided into two bailiwicks—Odense, which contains the capital of the same name, and Svendborg. It has annexed to it numerous small islands.

FUNERAL RITES. See BURIAL.

FUNES, GREGORIO, an Argentine historian, born in Cordova, S. A., died in the same city in 1920. The son of a wealthy proprietor, he was educated in the university which had been founded in Cordova by the Jesuits, entered holy orders, became dean in the cathedral church, and

attempted to introduce into the university the study of the higher mathematics, the law of nations, the modern languages, music, and drawing. During the revolutionary tumults the possessions of his father were confiscated by the royalist party. Funes had acquired a thorough historical knowledge of his country, which he put to use by writing the *Ensayo de la historia civil del Paraguay, Buenos Ayres, y Tucuman* (3 vols. small 4to., Buenos Ayres, 1816 *et seq.*), which contains an excellent epitome of the annals of a vast territory, of which but little was yet known in Europe.

FÜNFKIRCHEN (five churches; in Hungarian *Pécs*, which, in the language of the surrounding Slavic tribes, means five), a town of Hungary, capital of the county of Baranya, 105 m. S. S. W. from Buda; pop. 18,500. It is surrounded by rich vineyards, in the vicinity of mineral springs, and is one of the pleasantest towns of Hungary. It contains an old Gothic cathedral, built on the site of a Roman castle, 2 monasteries, a public library, several schools and hospitals, and a theatre. The population consists chiefly of Magyars, but the Slavic and German inhabitants are also numerous. The town has considerable commercial industry, its trade being chiefly in coal, alum, vitriol, wine, grain, tobacco, rape seed, wool, and other products of the neighboring country. Fünfkirchen is supposed to be the *Colonia Serbinum* of the Romans. In the time of Hungarian independence it was larger and much more important than now. History mentions that 2,000 of its students marched out to the battle field of Mohács, where the Hungarians were defeated by the Turks under Solymán, Aug. 29, 1526. This sultan passed some time at Fünfkirchen, during the siege of the fortress of Szigeth, and was so delighted with the place that he called it a paradise on earth. It remained in the hands of the Mussulmans from 1543 till 1686. During the late Hungarian revolution it was mostly in the hands of the Austrians.

FUNGI, an extensive family of cryptogamic plants, generally known under the names of mushrooms, toadstools, rusts, smuts, bunt, and mildews. They are, with rare exceptions, parasitic plants, growing upon and drawing their nourishment (or at least a part of it) from the substance of the object they infest. They occur in all parts of the globe, finding their maximum in the moist temperate zones; abounding in a climate like that of Sweden, which has produced more species upon a given area than any other known locality, except perhaps the southern United States. They are found wherever there is decaying vegetation, upon which they feed; and in some instances they prey upon living tissues, which they destroy by their attacks. Nothing of vegetable origin is free from their ravages when exposed to influences favorable to their growth. They are found also on animal dejections, on insects, whose death they cause, on the human skin, and even on bare stones, on iron which was in a forge a few

hours before, on read, and on chemical solutions. The disease in silkworms is caused by a mould (*botrytis bassiana*). The flies found adhering to our windows in autumn, fixed by the proboscis, are destroyed by a mould (*sporendonema musce*), which produces the little white rings between the abdominal segments and discharges its seed upon the glass around like a little cloud. The celebrated caterpillar fungus of New Zealand (*cordyceps Robertsii*), which infests the caterpillar of *hepialus virescens*, is a remarkable instance. Our American caterpillars are destroyed by another species (*C. militaris*). *Orygena equina* grows on the hoofs and horns of animals. Some of the microscopic species cause cutaneous disorders in the human system, and others have been found in the brains of birds. (See EPIPHYTES.) But these latter are exceptional cases. They principally affect decaying vegetation. Their vegetating fibres are of such extreme minuteness that they penetrate the hardest woods, and are thus powerful agents in their decay. Their delicate, evanescent, fragile mycelium fastens upon the fallen giants of the forest and hurries their slow decomposition. They attack the housekeeper's bread, cheese, vinegar, paste, yeast, preserves, and mustard, the farmer's corn and potatoes, the vintager's grapes, the gardener's berries, and the joiner's timber; while a host of forms prey upon the living tissues of plants, scarce any of which are free from their depredations, and many of which are assailed by a dozen different species at once. —Notwithstanding the long time which has been given to the study of fungi, there is no class of organized structures so little known. Their microscopic character, their abnormal growths, their polymorphic forms, have baffled the researches of the closest observers. Even at the present day, with all the light of modern science, the improved means of research, and the multiplied observations of a host of zealous students, a large proportion of the microscopic forms are but imperfectly understood. A century's study has left the subject an undeveloped and disputed field. It is only within a comparatively short time that an approach has been made to a clear insight into their laws of growth and reproduction. There are those, even now, who deem them to be of spontaneous or chemical origin, an opinion which their sudden appearance in vast numbers after a long rest, and their occurrence in closed cavities, have tended to establish. But this idea has been clearly disproved. That they are perfect plants, growing from and reproducing bodies analogous to seeds, is too firmly established to be questioned. When we ascertain that a single plant produces millions of these reproductive bodies, so small that they float on the air scarcely influenced by the force of gravity, that they may remain an indefinite period inert, and be called into sudden vitality by atmospheric changes favorable to their germination, their sudden appearance can be readily understood. They have been traced through their metamorphoses. The infinitesimally small spore has been watched in its growth

into a perfect plant; and one such observation, unquestionably made, is positive proof of their being perfect plants, having a development following certain laws; and we need not resort to the unsatisfactory theory of spontaneous or accidental origin, if indeed we are able to conceive of any vast assemblage of organized structures permanently reproductive, and identical through centuries, being the result of chance chemical action.—Fungi are of purely cellular growth. They form no woody fibre like flowering plants, nor do they form chlorophyl in their tissues. They consist of mere aggregations of homogeneous cells. Though many become corky, woody, and horny in the course of their growth, they have no other identity with true wood than of density and weight, possessing none of the complex structure of flowering plants. They exhibit a wonderful variety of external forms; but the composition of them all is the same, an aggregation of simple cells. Their earliest vegetation is a prolongation of the membranes of their spores, a name given to their reproductive seminal dust, which, though performing the office of seeds, differs from true seeds in being mere individual cells. From these arises a delicate, minute, webby growth, called the *mycelium*, which is the true vegetation of the plant, and which gives rise to the reproductive bodies at once, or builds up a receptacle which contains them. It is this mycelium which penetrates and destroys the object on which it is parasitic. It is made up of radiating and intertwining fibres formed of rows of cells placed end to end. These are in many instances so minute that they easily traverse the tissues of living plants and the pores of solid wood. From this mycelium grow the spores, which in their simplest form consist of the terminal cell or cells, which drop off to form new plants. They are of the extremest minuteness, appearing to the eye like a mere cloud of impalpable powder. As we rise in the scale, special branches and processes are formed to bear the spores, either singly or in groups. Still more complex forms build up a special organ called the *peridium*, within which the spores arise contained in little sacs termed *asci*. The large fleshy growths which we meet with in the woods or on trees are processes belonging properly to the reproduction and not the vegetation of the plant. They are very disproportionately large compared with the mycelium, and consist of a main stem called a *stipe* and an expanded top called a *pileus*, on which these spores are borne in various ways, on gills, ribs, prickles, spores, &c. The mycelium is sometimes reduced to a mere trace of evanescent, floccose growth; while the reproductive body becomes a fleshy mass, several pounds in weight. But the spores are always minute, being sometimes only $\frac{1}{1000}$ of an inch in diameter.—Fungi occupy an intermediate position between algae and lichens, into which orders they gradually merge at different points. Indeed, so

nice is the distinction at times, that some systematists have reduced lichens to a sub-order of fungi. They differ from the lichens in deriving their sustenance from the object on which they grow (though this has exceptions), in not producing a foliaceous thallus, and in not forming green chlorophyll; from algae, in being aerial, not aquatic, and in deriving their nourishment from their matrix and not from the surrounding medium. Such, at least, are the main points of difference. Those species of fungi which are found in fluids, such as the yeast and vinegar plants, are now proved to be merely submerged mycelia of certain moulds (*penicillium*), which do not attain their perfect stage until they reach the air. The propagation which takes place in fluids is due to a power the mycelium possesses of retaining its vitality under a variety of circumstances, of suffering division and enduring extremes of temperature. Beside this, it has a propagating power analogous to that of budding. In some aerial forms it goes on reproducing itself in peculiar ways, and rarely reaching the normal or perfect ascerous fructification. For this reason many species have been thought to be distinct plants when they are merely arrested stages of growth of one single species. Some aerial forms never reach a further growth than a compact, dense mass of mycelium. Oak trees sometimes contain a solid mass of a leathery texture (*xylstroma giganteum*), which never advances beyond that stage. The genera *sclerotium* and *rhiomorpha*, with their so called species, are mere compact bodies of mycelium, which have in some instances been artificially forced to develop themselves, and have produced plants of a widely different structure. The ergots of grain are objects of this kind. Tulane and others have watched their development into species of *cordyceps*. These forms remain constantly arrested; but very many of those which under favorable circumstances reach perfection remain similarly checked, and confuse the student with their multiple forms. This has caused the naming of hosts of species which are merely forms of others. There is no branch of science whose synonymy is more burdensome. It is almost a hopeless task to attempt to identify the species of authors by description alone, the plant itself being necessary for comparison. Long and continued observations are required to determine and connect the many forms which a single fungus may assume in the course of its existence.—Few objects in nature exhibit more gorgeous colors. The larger, fleshy forms present an endless variety of graduated tints. Some of the *boleti* exhibit on being broken a remarkable change of color, the white or yellowish hue of the interior changing instantly to a vivid blue. This is supposed by Prof. Robinson to be due to a molecular and not to a chemical change. Their texture is as variable as their color. Some are almost fluid, others fleshy, papery, leathery, corky, or hard and bony. Their size is equally various, from

mere specks to masses some feet in girth. Their rapid growth is astonishing. Puff-balls sometimes grow 6 inches in diameter in a night. Masses of paper pulp thrown out hot from a vat have been found within 24 hours filled and swollen with a species of *agaricus*. Schweinitz records the growth of a species of *athalium* found on a piece of iron which was heated the night before in a forge. Some of the ephemeral *ooprini* grow up in a night and melt away in the morning sun. Other species, like the *polypori*, grow very slowly and add a new layer every year, covering that of the previous season. Their expansive force in growing is very great. Notwithstanding their soft, yielding texture, agarics are able to raise heavy stones under which they spring up; and Bulliard tells of a *phallus* which burst a glass vessel in which it had been confined. They are meteoric in occurrence, depending upon peculiar states of the atmosphere. They generally appear in the greatest abundance in moist autumn weather, though some are found wherever there is moisture. Some depend so much on peculiar states of the atmosphere, perhaps electrical, that they appear suddenly and then disappear for a while. The pustular forms, however, which abound on the dead bark of trees, shrubs, old stumps, and fallen twigs, are more durable from their more solid structure. Some species of *agaricus* possess a remarkable luminosity, and certain *rhiomorpha* growing in mines shed a phosphorescent light of extreme brilliancy. Fungi differ from flowering plants in their chemical influence upon the air. They absorb oxygen and exhale carbonic acid, performing the same office in this respect as animals, which they most resemble in chemical composition, in being highly azotized. The odors they emit in decay are more like putrescent animal than vegetable matter. The fleshy sorts generally possess a peculiar earthy odor, but some species of *phallus* and *clathrus* emit a most intolerably offensive stench, which will render a close apartment untenable. Others, on the contrary, are very agreeable to the smell, and some in drying acquire a fine aroma. They are quite as variable to the taste. The prevailing flavor is rather negative and peculiar to the order; but they are also bitter, acrid, biting, astringent, oily, and nauseous, as well as savory and agreeable. Most of them lose these qualities in drying.—Fungi have been used as an article of food for untold centuries. The writings of the ancients make frequent mention of them as among their most esteemed viands. They are extensively eaten in Europe by all classes, and many works have been written laudatory of their virtues, with copious directions for dressing them in a great variety of ways. Notwithstanding the virulent poisonous qualities of some, others are eagerly sought for, and in some places it is said that the people have burned down woods to get certain species of fungi whose growth followed the combustion. But in America they have been regarded as noisome and disgust-

ing by the great mass of the people; they have been usually despised as the unsightly evidences of decay, rather than eagerly collected as delicious food, which many of them are. Badham states that the return of taxed mushroom-rooms in Rome during a period of 10 years gave a yearly average of between 60,000 and 80,000 lbs. weight, beside the untold quantity consumed which did not fall under government notice. He estimates that in that city alone the annual consumption would reach a value of \$20,000. They form an extensive article of food for the poor all over Europe, and some species are sought for at high prices by the rich. The species commonly cultivated, the mushroom proper, is the *agaricus campestris*, which grows wild in old fields and pastures, but is propagated by planting its spawn, which is the mycelium of the plant, in hot-beds. Although this is the most widely used, many other species are equally excellent. The truffle (*tuber cibarium*) grows beneath the ground, and is eaten with avidity by different animals. Dogs are trained to scent it out by those who collect truffles for market. Their reputation as aphrodisiacs is thought to be unfounded, having its origin in the old doctrine of resemblances. *Polyporus tuberaster* grows from the celebrated fungus stone *pietra fungbia*, which is a mass of earth traversed by the mycelium of the plant; the latter is watered from time to time and produces successive crops. The heads of poplar trees are watered in autumn, and they then bear the *agaricus caudicinus*, greatly esteemed. Blocks of the hazel tree are singed over straw and watered, and they produce in abundance the *polyporus corylinus*. Among other species eaten, the principal are *agaricus prunulus*, *orcella*, *procerus*, and *exquisitus*, *lactarius deliciosus*, *cantharellus cibarius*, *boletus edulis*, *marasmius oreades*, *hydnum repandum*, *fistulina hepatica*, *morchella esculenta*, and *helvella crispa*. These are all fleshy fungi. Many other species known to be at times poisonous are eaten in different countries in different ways. They are dried, pickled, salted, and cooked in an endless variety of fashions. Some of the most virulent poisons are found among fungi, and many fatal accidents have arisen from the eating of poisonous species, yet fungi which are known to be ordinarily injurious are eaten with impunity by some. Rye meal containing large quantities of ergot produces a terribly disgusting and fatal gangrenous disease; while the ergots themselves are eaten largely in the north of Europe by children, under the name of St. John's bread, without any such result. Pickling and salting renders many innocuous. *Agaricus muscarius* is one of the most injurious; yet it is used as a means of intoxication by the Kamtchatkadeals. One or two of them are sufficient to produce a slight intoxication, which is peculiar in its character. It stimulates the muscular powers, and greatly excites the nervous system, leading the partakers into the most ridiculous extravagances. The only fungus used at the

present day in medicine is the ergot of rye, sometimes employed in cases of protracted labor. Several others have been used in times past like the *cordyceps Sinensis*, a sphaeroid species parasitic on a caterpillar; but these are now thought to be of no value. The *lycoperdons* or puff-balls have been used as styptics. Some *polypori* make admirable razor strops when sliced with a sharp knife. *Polyporus fomentarius* and *igniarius* have for many years furnished the punk which is used as tinder; the corky portion being pounded till its compact mass of soft, silky fibres becomes loosened and flexible. *Agaricus muscarius* is used as fly poison.—Some fungi are among the greatest pests of the agriculturist. The rusts, smuts, and bunt of grain are all fungi of the genera *uredo*, *ustilago*, and *puccinia*. Their mycelium penetrates the tissues of the plants, destroys their vitality, and bursting through their cuticles, covers them with myriads of their orange, brown, yellow, or black spores. They probably induce decay by a chemical influence which they exert on the juices of the infested plant, as well as by their mechanical interference with its organism. It has been a question how their spores are carried into the tissues, where their earliest growth is entirely separated from the outer atmosphere. But when we remember their extreme minuteness, we can understand that they may be drawn up with the fluids which enter the roots, or receive them directly into their tissues through the infinity of breathing pores with which the surfaces of the plants they infest are perforated. The mildews of the grape and other fruits are myceloid growths, which in certain stages have been thought to be perfect plants (*oidium*), from their possessing a power of reproduction. Certain cells take on a vesicular growth filled with a mass of minute bodies which were thought to be the true fruit. But the later observations of Léveillé, Tulasne, and others, have shown that these are arrested stages of growth of an entirely different ascigerous genus, *erysiphe*. These produce their fruit in minute black pustules, from the base of which peculiar radiating processes arise, sometimes of great beauty. The mildews grow on the surface of fruits, and injure them more by choking up their pores and mechanically confining them with their dense, felt growth, than by abstracting their juices. The potato rot is accompanied by a rapid growth of the mycelium of *botrytis infestans*, which penetrates the leaves, stems, and tubers, inducing rapid decay. It appears on the surface in the form of a minute whitened mould. Many other plants are similarly affected. *Boleti* are sometimes traversed by a minute mould, *sepedonium chrysospermum*, which gives a golden yellow hue to the flesh. Dry rot in timber is caused by the penetrating mycelium of *merulius lacrymans* and *polyporus destructor*. The black excrecent growth on plum trees is occasioned by the *sphaeria morbosa*, which covers the warts its mycelium has made with its minute black, compacted *perithecia*. The fairy rings which, in olden times, were

thought to be the scenes of midnight fairy revels, are produced by the growth of different species of *agaricus*. As they exhaust the soil by one year's growth, their mycelium pushes into the richer portion around; and thus they extend the circle of their growth, furnishing by their decay a manure for the next year's grass, which is darker and denser in consequence. This is one of the many instances where exact observation has reduced the fanciful ideas of superstition and poetry to the less romantic but more satisfactory basis of natural causes.—Fungi have been classified in various ways by different mycologists. By the early writers they were arranged according to their external appearances; but as more exact means of observation multiplied, their microscopic structure became better known, and a nearer approach was made to a classification in consonance with their true affinities. From Oësalpinus in 1588 to Nees von Esenbeck in 1817, the progress of knowledge was comparatively small for a period of nearly 250 years. But in 1821 appeared the *Systema Mycologicum* of Elias Fries, a work of the most learned and profound character, evincing a comprehensiveness and thoroughness far surpassing all that had preceded it. It is even now the great work to which all students refer, though since that time a host of observers have been exploring this obscure field, and collecting a vast array of facts concerning the laws which govern these minute organisms. Minds of the first class are engaged at present in the elucidation of their structures—Montagne, Léveillé, Tulane, Berkeley, Desmazières, and many others. The latest system given to the world is that in the Rev. Mr. Berkeley's "Introduction to Cryptogamic Botany," which is essentially similar to that of Fries. The two principal divisions are: *sporidiferi*, spores contained in special sacs called *asci*; and *sporiferi*, spores naked, not enclosed. These are again subdivided into 6 principal orders, all formed on the mode in which the spores are borne, viz.: 1. *Ascomycetes* (Berk.), spores produced in little sacs (*asci*), and formed out of the protoplasm they contain. This order comprises a vast number of the black, pustular growths, abundant on dead wood, bark, twigs, leaves, &c. They are generally formed of a mass of carbonized cells arranged in the form of hollow spheres or cups called *perithecia*. Within these grow the *asci* containing the spores, which escape either from a pore in the perithecium or by its breaking up irregularly. The basal cells bearing the *asci* are collectively termed the *hymenium*. Among these are the mildews (*erysiphe*) and the black mildews (*capnodium*), and the whole great tribe of *sphæria*. The truffles (*tuber*) also belong here. They are subterraneous, fleshy forms, whose substance is intersected by veins which are inward folds of the hymenium, covered by the expanding growth of the fleshy receptacle. The morels (*morchella*) and the *helvelles* are carnosae, bulky forms, which have their *asci* on the outer surface of a variously folded, wrinkled, and pitted

hymenium. The *cyttaria* is akin to these, of a sub-gelatinous consistence. These are all made up of compacted cells, forming horny, carbonized, or heavy, fleshy masses. 2. *Phycomycetes* (Berk.), spores growing in bladder-shaped cells on the end of delicate, individual, scattered fibres, composed of cells applied to each other in a linear series. A small group comprising the true moulds (*mucor*). 3. *Hyphomycetes* (Fr.), spores naked, simple, or aggregated on the ends of fertile threads. These differ from the last in the naked growth of the spores. Here belongs the great host of minute moulds which cover almost every substance exposed to dampness with their floccose fibres. Nothing organic is free from their attacks. Their colors are sometimes extremely beautiful. To this order belong the mould of the potato rot (*botrytis infestans*), and many which induce decay in fruit (*oidium*), the bread and cheese moulds (*penicillium*, *aspergillus*), the rigid black moulds (*cladosporium*, *helminthosporium*), and the yeast and vinegar plants, which are submerged mycelia of *penicillium*. 4. *Coniomycetes* (Fr.), spores naked on the ends of filaments or vesicles; hymenium sometimes obsolete, sometimes contained in a perithecium. This order differs from the last in having scarcely any filamentous growth, and in having the spores produced in the utmost profusion, greatly disproportionate to the rest of the plant. It comprises an infinity of minute pustular forms, which infest the tissues of every variety of plant, many presenting to the eye but a mere speck on their surface. Here belong the whole family of rusts, smuts, and bunt (*puccinea*, *uredo*, *ustilago*, *tilletia*, *acidium*, &c.), which creep through the tissues of living plants, and finally burst forth on the exterior and fructify in dense, dusty masses, which cover their whole surfaces. Different species affect different organs, some being on stems and leaves, others on flowers and fruit. They are the scourge of the farmer, whose fields they devastate. The savin trees (*juniperus*) are attacked by a peculiar genus (*podisoma*), which bursts from their bark and swells under the influence of moisture to a gelatinous mass. It also occasions the globular excrecent growth called cedar apples, from orifices in which it protrudes in long orange-colored spurs, formed by the spores, tipping the aggregated mass of filaments. The black, irregular scars on apples are caused by the *spilocaea fructigena*. An extensive group of this order comprises those minute pustular forms which, resembling the true ascigerous fungi in many respects, differ in producing their spores on the ends of the filaments instead of being contained in *asci*. There is great obscurity overhanging this whole group. They exhibit themselves in so many anomalous forms that it is almost impossible to establish limits to genera which may be clearly understood. Writers on the subject record great numbers of genera, but hardly any two agree upon their characters, and the whole subject is burdened with an inhar-

monious synonymy. New light has been shed upon the subject of later years by the observations of Berkeley, Léveillé, Tulasne, and others, who have pretty clearly established the fact that many so called genera are merely stages of growth of true ascigerous fungi. Some genera, such as *erysiphe*, are known to produce several different kinds of reproductive bodies; and Tulasne has carried his researches into this manifold fructification, showing that many ascigerous species are attended by processes (*pycnidia*) which produce minute bodies (*spermatia*, *stylospores*) differing much from true spores, and growing beside them, sometimes within the same receptacle. He has demonstrated that certain growths recorded as distinct species of different genera and orders are, in fact, different forms of one single plant, whose perfect state is ascigerous. If such be true of the few whose progressive growth has been followed, we may safely conclude that the whole mass of coniomycetoid species, or at least those of the sub-order *sphaeronemati*, may be arrested or non-developed stages of growth of higher ascigerous forms. Such being the case, the classification of this whole order of plants will one day need rearrangement. 5. *Gasteromycetes* (Fr.), mycelium gelatinous, floccose, or cellular, giving rise to a stalked or sessile peridium, composed of one or more coats; the spores borne on the apices of filaments lining the interior. This includes the whole tribe of puff-balls, as well as the subterranean fungi which look like truffles, but are dusty and smutty within. The peridium is generally of a rounded form, cracking in various ways at maturity, and giving forth myriads of spores like a cloud of dust. In some the hymenial tissue dries up at maturity, leaving the spores free (*lycoperdon*); in others it resolves itself into a fluid which drips from the elongated receptacle (*phallus*). In some it retains its form, after parting with its spores, in an intricate mass of anastomosing fibres (*trichia*, *arcyria*). The *athalium*, which infests the hot-beds of greenhouses, belongs here. The earth stars (*geaster*) are peculiar in the dehiscence of the outer peridium, which splits into segments and unfolds in a starry manner; it is also very hygrometrical, unfolding or closing as it is moist or dry. The little bird's nest fungus (*crucibulum*) is peculiar in having its spores in distinct masses at the bottom of its nest-like peridium, looking like little eggs. *Sphaerobolus stellatus* has the remarkable power of projecting its sporangium to a great distance; the lower, internal part of the peridium is suddenly inverted at maturity, ejecting its soft sporangium, of the size of a mustard seed, several inches. The species of *phallus* and *clathrus* are notorious for the intolerable stench of their dissolving hymenium. 6. *Hymenomycetes* (Fr.), mycelium floccose, webby, giving rise to a distinct hymenium, borne either immediately on the mycelium or on special receptacles bearing the spores on gills, wrinkles, tubes, prickles, &c. Here occur the jelly-like *acidia*, so common

on trees after rains; the branching coral-like *clavaria*, abounding in our woods in autumn, all of which are edible; the corky *polypori*, bearing their spores in minute, compacted tubes beneath the receptacle termed a *pileus*; the *boleti*, which resemble the last except that they are fleshy, and of which many are eaten; the *hydna*, which bear their spores on the exterior of prickly-like processes; and, lastly, the *agarici*, which include the edible mushrooms and kindred forms, whose spores are borne on radiating blades beneath a cap borne up by a stem like an umbrella.—Mycology, as the study of fungi is termed, is among the most recondite of pursuits. Among the authors whose works are of principal value are Berkeley, Bulliard, Corda, Desmazières, Fries, Greville, Klotzsch, Kromholz, Léveillé, Link, Montagne, Nees von Esenbeck, Persoon, Schaefler, Schweinitz (for American species), Sowerby, Tulasne, Vittadini. The principal American authors of the present day are the Rev. Dr. M. A. Curtis and Mr. H. W. Ravenel.

FUNGIBLE, a word supposed to be derived from the phrase *functionem recipere*, in the civil law. It is not much known in English law, but is often used in French and Scotch law, and has recently been introduced into American legal language. It is used to mean what we have no other word for, that is, *res quæ pondere, numero, et mensura constant* (1 Bell's "Commentaries," p. 255), or things which may be returned or replaced by any others of the same kind, in contradistinction from those which must be returned or delivered specifically. Thus money is nearly always a fungible, because so much paid in any way that is a legal tender satisfies a claim for it. But it might happen that A lent B certain specific coins, for a specific purpose, which were to be specifically returned; and these would not be fungibles. If one lent to another corn, or meat, or manure for his fields, to be used, and return to be made in a like quantity of things of like quality, they would all be fungibles.

FUNNEL, an instrument for facilitating the transfer of fluids into vessels furnished with small apertures, being of the nature of a pipe opened out into a wide conical-shaped mouth, into which the fluids are first poured, their discharge being through the small end, which is placed in an aperture of the vessel to be filled. They are also of great service in filtering by the support they furnish to the filter and its contents. For chemical purposes funnels of porcelain or glass are commonly employed; recently excellent funnels have been made of gutta percha, which are free from risk of injury by breaking, are easily kept clean, and are liable to be affected by but few chemical agents.

FUR, the thick, warm covering of certain animals, especially such as inhabit the lands or waters of cold countries, distinguished from hair by its greater fineness and softness; also, and most generally, the skins of such animals dressed with the fur on. Before being dressed by applications upon the inner side to keep the material soft, the

skins are known in commerce as peltry. Fur is used especially for winter clothing, for which it is well adapted not merely by reason of its important qualities of warmth and durability, but also on account of its great beauty. In all cold climates man has availed himself liberally of the warm covering with which nature has clothed the animals around him; but the wealth of the most favored nations has drawn to them the most beautiful furs, in whatever part of the world they are procured. Skins of animals were among the first materials used for clothing. Before Adam and Eve were driven from the garden of Eden they were furnished with coats of skins (Gen. iii. 21). The appearance of Esau is compared to that of a hairy garment (Gen. xxv. 25). The ancient Assyrians used the soft skins of animals to cover the couches or the ground in their tents (Judith xii. 15); and the Israelites employed badgers' skins and rams' skins dyed red as ornamental hangings for the tabernacle (Exod. xxxix. 84). The ancient heroes of the Greeks and Romans are represented as being clothed in skins, Æneas wearing for an outer garment that of a lion, and Alcestes being for fearfully clad in that of the Libyan bear (Virgil, lib. v.). The Odyssey also has occasional reference to the same costume. Propertius designates the earlier senators as *pellati*; but the Romans of later periods regarded the clothing as that of barbarous times and people, associating it with the habits of the rude Scythians and of the other savage tribes on their eastern and northern frontiers. But in the 3d or possibly the 2d century of the Christian era, fur dresses appear to have been in use and in high estimation with the Romans. They were introduced by the northern tribes, and were probably at that time prepared with much skill. Ancient historians make frequent mention of this kind of clothing in use by the people of various nations. Herodotus speaks of those living near the Caspian sea wearing seal skins; and Cæsar mentions that the skin of the reindeer formed in part the clothing of the Germans. Ælianus in his history of animals, written in Greek in the 2d century, makes mention of the skins of the Pontic mouse, which were sent to Persia, and which were sewed together to form warm dresses. Plutarch speaks of Pharnabazus the Persian as reclining upon soft furs. Beckmann thinks that the term *mus* was applied as a general name for most strange small-sized animals, as the term *dos* with some expletive was to the larger ones met with in other countries; but while some think the earless marmot was commonly meant by the Pontic or Caspian mouse, he believes that the animal was the ermine, named probably from Armenia, to which country it was introduced at an early period from more northern regions. The fur of the beaver was in use, either in the skin or for manufacturing fabrics, in the 4th century; the animal was known as the Pontic dog. The sable of the far off regions of Siberia was not known till many centuries later; but it was the produc-

tiveness of that region in furs that chiefly prompted the Russians to its definitive conquest.—In the early periods furs appear to have constituted the whole riches of the northern countries; they were the principal if not the only exports; taxes were paid with them, and they were the medium of exchange. So it was in our own western territories in the latter part of the last century, and still continues to be among the Indians. In the 11th century furs had become fashionable throughout Europe. The art of dyeing them was practised in the 12th century, chiefly of a red color. In the history of the crusades frequent mention is made of the magnificent displays by the European princes of their dresses of costly furs before the court at Constantinople. But Richard I. of England and Philip II. of France, in order to check the growing extravagance in their use, resolved, in the crusade about the end of the 12th century, that neither should wear ermine, sable, or other costly furs. Louis IX. followed their example in the next century; and well he might when the extravagance had grown to such a pitch that 746 ermines were required for the lining of one of his surcoats. In these times the use of the choicer furs, as those of the ermine, sable, the vair or Hungarian squirrel, and the gris, also supposed to be a squirrel, was restricted to the royal families and the nobility, to whom they served as distinctive marks and badges of rank, and were for this purpose introduced into armorial bearings. These privileged persons applied them lavishly to their own use; and the fashion extended to the princes of less civilized nations, if it was not indeed originally adopted from them. In 1252 Marco Polo observed that the tents of the khan of Tartary were lined with rich skins, and among them those of the ermine brought from countries far north—"from the land of darkness." In 1387 the use of furs, which had become common in England, was prohibited by Edward III. to all persons not able to expend £100 per annum. The early trade of western Europe in furs was through the Hanse merchants on the south coast of the Baltic, who received them from the ports of Livonia. In the 16th century a direct trade was opened between the English and Russians; and a company of the former, protected by the czar, established posts on the White sea with a warehouse at Moscow, whence they sent trading parties to Persia and the countries on the Caspian. The czar sent presents of beautiful furs to Queen Mary and to Queen Elizabeth; but the latter prohibited the wearing of any but native furs, and the trade soon declined and was abandoned. Siberia was conquered by the Russians in 1640, and its tribute was paid in furs. This country also furnished large quantities to China; but the choicest kinds, the precious ermine of Yakootsk, the brilliant fiery foxes, and the best sables, were taken to Moscow and Novgorod for the use of the princes and nobles of Russia, Turkey, and Persia.—The early settlers of the northern

provinces of North America soon learned the value of the furs of the numerous animals which peopled the extensive rivers, lakes, and forests of these vast territories. They collected the skins in abundance, and found an increasing demand for them with every new arrival from the mother country. Trinkets, liquors, and other articles sought for by the native tribes, were shipped to Quebec, and forwarded up the St. Lawrence to Montreal, which became among the French settlements the principal trading post. The Indians were stimulated by trifling compensation to pursue their only congenial peaceful occupation. The Frenchmen, readily assimilating to the Indian habits, became themselves hunters and explorers. Of hardy constitutions, roving propensities, not deficient in courage, yet of mild and peaceable dispositions, they were admirably adapted to penetrate with safety among the strange tribes of savages, and to conciliate and secure the good will of these people, or manage them by their superior address. They carried moreover the fire water and the gewgaws which they well knew how to use to their own advantage. The classes of *voyageurs* and *courriers des bois*, to which this trade gave rise, became the pioneers of all the new settlements, and to this day they continue to be the main dependence of the exploring expeditions sent into the distant interior. Unrestrained by law and beyond all control, they fell into excesses which the French government sought to check by restricting the trade, under penalty of death, to those upon whom it conferred licenses; but the same voyageurs were employed by the merchants into whose hands the licenses came. The latter fitted out expeditions of two canoes each, with goods to the amount of 1,000 crowns for 6 voyageurs, who were expected to return in a year or two with double the number of canoes and peltries to the value of about 8,000 crowns. In this case, the merchant being repaid his outlay, cost of license, and proportion of profits, the share of the voyageurs would be about 600 crowns each. To protect and control the trade forts were soon required in the Indian territory. That established at Mackinaw was not long in becoming an important central point, taking in some respects the place of Montreal itself. The English during this time had not been neglectful of their interests in securing a share of this valuable trade. Its importance early engaged the attention of wealthy and influential parties connected with the government of Great Britain, as Prince Rupert, the duke of Albemarle, the earl of Craven, Lord Ashley, and others. After a successful enterprise in which they had embarked they obtained from Charles II. in 1670 a charter of incorporation, giving to them full possession of the territory within the entrance of Hudson's straits not already granted to other subjects, or possessed by those of any other Christian prince or state. In this was included the monopoly of all trade in these regions, and this was the origin of the Hudson's

bay company. The territory they claimed extended from Hudson's bay west to the Pacific, and north to the Arctic ocean, excepting that occupied by the French and Russians. They soon formed settlements upon the rivers which empty into Hudson's bay, and carried on their operations with great vigor and success. Though opposed by the French settlers and adventurers, who resisted their claims and subjected them to vast expenses and losses, the company in 1684 paid a dividend of 50 per cent., in 1688 the same, and in 1689 one of 25 per cent. In 1690 the capital stock was trebled without call upon the shareholders, and a dividend of 25 per cent. upon the new stock was paid. The company continued to prosper notwithstanding the persistent opposition of the French. Their forts or factories were extended further into the interior of British America; and their power was supreme throughout the country, and in great measure over the Indians whom they employed to collect the skins. Still their charter had never been ratified by act of parliament. In 1749 a question arose in parliament respecting their rights, which was decided in their favor. But the Canadians do not appear to have admitted their exclusive privileges, particularly over the large territories ceded by the French to the English in 1763. They therefore organized a company in the latter part of the last century, composed of some of the chief merchants of Canada, under the name of the north-west company. Their head-quarters were at Montreal, and their operations were carried on with great energy in the interior, extending to the rivers that flow into the Pacific, where they established factories about the year 1805. The annual meetings of the active partners were held at Fort William at the mouth of Pigeon river, on the N. shore of Lake Superior. Their clerks and servants, of whom the former were mostly young Scotchmen, and the latter Canadian voyageurs, amounted to about 2,000 in number. The company thus soon became a formidable competitor with the Hudson's bay company for the furs of these regions. In 1813 they acquired possession of Astoria on the Columbia, the settlement having been sold to them by Mr. Astor's partners in consequence of the war between the United States and Great Britain. The two companies were afterward involved for two years in actual war. In 1821 they united in one company, called the Hudson's bay company, with the privileges of the old company extended by act of parliament over all the territory occupied by both. The license granted on May 30, 1838, for 21 years, expired in 1859. Owing to the depreciation in the value of beaver skins and others of this class, which formerly made a large portion of the profits of the company, the renewal of the license is of comparatively little importance. The company, however, possess large establishments scattered from Labrador to the Pacific, and from the northern boundaries of Canada to the Arctic ocean, which are of no value for any other purpose, and which yielded

in 1855 a dividend of about 6 per cent. on a capital of £400,000. Their affairs in America are conducted by a chief superintendent (now Sir George Simpson), a deputy governor, and a committee of 7. They employ 25 chief factors, 28 chief traders, 152 clerks, 1,200 regular servants, and an indefinite number of natives as occasion requires; also a steam vessel and 5 sailing vessels, all armed. Their great sales of furs take place in the month of March, so timed as to be completed before Easter, and again in September, every year in London, and are attended by purchasers from the continent, from the United States, and other parts of the world. A great annual fair for the sale of furs, to which many are taken from London, is held at Leipsic, a famous mart in this trade.—The importance of the fur trade led to the early settlement of the western territories of the United States. The first organization for carrying it on was that commissioned in 1762 by Mr. D'Abadie, director-general of Louisiana, made up by merchants of New Orleans, under the title of *Pierre Liguette Laclede, Antoine Maxan, and co.* Laclede, the principal projector, conducted the expedition to St. Genevieve, Mo., arriving there Nov. 2, 1763. The same year he selected for the site of his establishment the spot now occupied by the city of St. Louis, and then gave it the name it has since borne. The place soon became of similar importance to Mackinaw and Montreal. The brothers Auguste and Pierre Chouteau were of his party, and they remained ever afterward in the country, connecting their name not merely with the history of the trade they established, but with that of the region itself from the time it was a wilderness till it became a populous and important portion of the United States. To this day the name commands respect among all the Indian tribes north and west. The vast Indian territories bordering the great tributaries of the Missouri and the Mississippi opened a boundless and almost unexplored field for the operations of the fur traders. Hostile tribes were often encountered, but none long checked their enterprise. The Rocky mountains served only for a time as a barrier to their explorations, their trading posts, before 10 years of the present century had elapsed, being established on Lewis and Columbia rivers. No other business was conducted throughout these regions but what was connected directly with the fur trade; agriculture and all the other resources of the country were neglected for this exciting and adventurous occupation. The furs, collected by long and tedious navigation in canoes and Mackinaw boats from the most distant sources, were run down the dangerous rapids of the streams, and laboriously packed upon the backs of men over the portages around falls, and past the shoals which the hardest voyageurs might not navigate. Their market was then reached by another voyage of several months to New Orleans, where they were exchanged for a return freight of groceries; or in the other direction to the great trading post of Mackinaw,

whence the voyageurs came back with English goods, the returns from England in fact for furs taken to Mackinaw 4 years previously, and then boated down the lakes and the St. Lawrence to Quebec. The annual cost of the goods in the early years of the trade was about \$35,000. This was doubled by the expenses of transportation from Mackinaw; but the profits were nevertheless rated at 800 per cent. During the last 10 or 15 years of the 18th century the value of the goods annually sent up the Missouri in exchange for furs was estimated to average \$61,000. Little money was seen in these transactions; the currency was shaved deer skins. The average annual value of the furs collected at St. Louis for 15 successive years, ending in 1804, is stated to have been \$203,750. The number of deer skins was 158,000; beaver, 86,900 pounds; otter, 8,000; bear, 5,100 skins; and buffalo, which is now by far the most important fur, only 850. The Missouri fur company was founded in St. Louis in 1808, consisting of the Chouteaus and several new associates. By this association an expedition was sent across the Rocky mountains under Major A. Henry, and the first post established on the Columbia river. The company was dissolved in 1812, and new associations of its members were formed the same year for continuing the trade independently of each other; but their operations were rarely extended beyond the Rocky mountains. This trade in connection with St. Louis was not renewed until the expeditions of Gen. W. H. Ashley in 1823 and 1824, who by extraordinary enterprise and perseverance succeeded in bringing to St. Louis, between 1824 and 1827, furs to the value of \$180,000. He then sold out to the Rocky mountain fur company of St. Louis, and this association conducted for several years an extensive business, their parties running over nearly the whole of California and all the country about the southern branches of the Columbia. The dangers to which they were exposed from Indians and accidents were so serious, that $\frac{2}{3}$ of all the men employed from 1825 to 1830 lost their lives in the service. The other traders of St. Louis during this time were united for 6 years in the firm of B. Pratte and co., excepting the western department of the American fur company, a branch of his house which Mr. Astor of New York established in 1819 in St. Louis. His gigantic operations of an earlier date will be presently noticed. In 1834 this department, on the retirement of Mr. Astor from business, was sold to Messrs. B. Pratte, Pierre Chouteau, jr., and Cabanné of St. Louis, who conducted the business till 1839, when the still existing organization of P. Chouteau, jr., and co. was formed. For 40 years preceding 1847 the annual value of the trade to St. Louis is supposed to have been between \$200,000 and \$300,000, and the latter half of this term much more than the larger sum named; but it was of still greater importance in developing the resources of the wild territories west of the Mississippi, and opening these to the settlement of civi-

ilized races.—Of the eastern merchants engaged in this trade, the most prominent was Mr. John Jacob Astor, who embarked in it in 1784, at the same time making his residence in New York. He was a purchaser of furs in Montreal, which until the treaty of 1794 or 1795 could be taken only to England for sale. Afterward he introduced them into New York, whence he shipped them to different parts of Europe and to China, his ships bringing from the latter in exchange the rich products of the East. About the year 1807 he engaged in the trade on the northern frontier, competing with the wealthy companies of Canada that had long occupied this field. His projects were directed to an object of great national importance, long desired by the government of the United States, but in which it could take no direct action, viz., the diversion of this great trade from foreign companies to the benefit of our own commerce and the increase of its revenues. In 1808 he obtained from the New York legislature a charter for the "American Fur Company," with a capital of \$1,000,000, and the privilege of increasing it to \$2,000,000. The capital he furnished himself, but preferred to act under the name of a corporation. In 1811 this corporation was merged, on the buying out of the Mackinaw company of Canada, in another called the "South-west Company." In 1809 Mr. Astor gave his attention to the project, suggested many years before by Sir Alexander Mackenzie especially for the benefit of the British companies, of establishing a line of communication across the continent from the Atlantic to the Pacific ocean, and concentrating in one operation the entire fur trade on both coasts, to the territories already occupied by the Hudson's bay company on the north and the Russians on the north-west. He sought an association with the north-west company of Canada, to whom he could offer a means of shipment of furs from the Pacific coast to China, a privilege which was monopolized in British territory by the Hudson's bay company. The north-west company declined the proposed association, and sought to anticipate Mr. Astor in effecting a settlement at the mouth of the Columbia. Some of its late officers, however, became associated with Mr. Astor in June, 1810, and a company was formed styled the "Pacific Fur Company." An expedition was forthwith sent round by sea to the mouth of the Columbia, and another was organized to proceed from Montreal to Mackinaw, thence to St. Louis and up the Missouri, on the way across the continent to the same destination. One of the party which went by sea was Mr. Gabriel Franchere, who is still engaged in the fur trade in New York, and whose published narrative is the chief historical record of these important expeditions. The land party was accompanied by Mr. Ramsay Crooks, a young Scotchman, who returned by land in 1818, and afterward became distinguished as a partner and successor of Mr. Astor in the trade, continuing in it till his death in 1859. Each year similar expeditions were to be despatch-

ed at the expense of Mr. Astor, his associates devoting themselves to the enterprise, and receiving half the shares. Mr. Astor nobly performed his part of the scheme, for 3 successive years despatching a ship to the support of the colony with instructions to trade for furs upon the coast, and proceed with them and what were collected at the mouth of the Columbia to China, returning with India goods to New York. He anticipated years of outlay, and by his articles of agreement was bound to furnish funds to the amount of \$400,000. A succession of misfortunes attended the enterprise; but Mr. Astor was not disheartened, and through his courage and support it would no doubt have resulted in complete success, but for the treachery of his principal Canadian partner, who, under the pretence that the property on the Pacific must be seized by the British cruisers during the war, disposed of it all for a mere nominal price to the rival north-west fur company, and associating himself with them, transferred the settlements to the protection of the British flag, Oct. 16, 1813. The operations of Mr. Astor were after this limited to the country on this side of the Rocky mountains, his principal establishment being at Mackinaw. Before Lake Superior became known in 1844 for its copper mines, it was visited only by those connected either with the reorganized American fur company, which maintained an establishment at its outlet, and supported a brig named the Astor upon the lake; or by those belonging to the Hudson's bay company; or by parties in the employment, as soldiers or otherwise, of one of the two governments. Up to 1848 the fur trade was the sole business interest of the territory of Minnesota. The trading posts of St. Paul and Mendota controlled the neighboring territories of the Winnebagoes and Chippewas, of the Sioux and the Dakotas; but since 1852 the decline of the business has left the great fur company of Pierre Chouteau, jr., and co. no inducement to continue their operations, and the reduced trade is now conducted by smaller houses, composed, however, of some of the old fur traders. The trade is limited almost entirely to the Pembina or Red river region, and that around the head waters of the Mississippi, and the St. Peter's or Minnesota. The exports of furs from St. Paul in 1856 were as follows:

Animals.	No. skins.	Value.
Muskrat	64,292	\$11,572 56
Mink	8,276	18,691 00
Marten	1,428	8,570 00
Fisher	1,045	4,702 50
Fox, red	876	1,095 00
" cross	20	100 00
" silver	8	400 00
" kitt	2,549	1,271 00
Raccoon	2,400	2,550 00
Wolverine	2,082	3,043 00
Otter	405	1,417 50
Beaver, lbs.	586	881 00
Bear	610	6,700 00
Lynx	60	125 00
Buffalo robes	7,500	41,800 00
Total value		\$97,253 56

In 1857 the total value of the furs was \$182,491, and in 1858 \$161,022, the decrease in 1858 being the result not of reduced quantity but of lower prices of furs. St. Paul is becoming a great depot and outlet for the fur trade. Prior to 1844 the entire fur product of the Red river valley, north and south of the British boundary, was collected by the agents of the Hudson's bay company, and sought the seaboard through Nelson's river and Hudson's bay. In 1844 an effort was made from St. Paul to get the furs of the Red river valley. The first year only \$1,400 worth came that way; in 1856 the value amounted to \$75,000. From Pembina, in 1857, there were received at St. Paul \$120,000 worth of furs.

The variety of furs in use and the importance of the trade are well exhibited in the following table of the importations and exportations of the English market in 1851, and of the importations in 1855-'6. The number of skins imported in 1851 was estimated at about 5,000,000. The omission of buffalo (bison) robes will not fail to be noticed. These, which constitute the largest item of the domestic trade in furs of the United States, being annually procured from the western territories to the amount of more than 100,000 skins, do not reach the English market, and are rarely exported to Europe. In the Crimean war they were sent there in some quantity to be used in the tents of the soldiers.

Animals.	1851.			Importations from Sep. 1, 1855, to Sep. 1, '56.		
	Total imp't'd into England.	Exported.	Consumed in England.	By Hudson's Bay Company.	From the U. States.	Total.

Wild cat	500	8,823	9,323

The skins of the raccoon (*procyon lotor*) are obtained from the American continent; they are finally sent to Germany and Russia, where, on account of their durability and cheapness, they are in demand for linings for coats, &c. The fur of the beaver (*castor Americanus*) was formerly highly prized in the manufacture of hats, and it made a considerable portion of the profits of the fur companies. It constituted the largest item in value among furs. In 1839 a single skin was worth in London 27s. 6d.; in 1846, 3s. 5d. In the former year 55,486 skins sold for £76,312; in the latter year 45,389 skins sold for £7,856. Cheaper materials had been substituted in making hats, and the demand had nearly ceased. By a new process the skin is now prepared to make a handsome fur for collars and gauntlets, and its fine silky wool has also been successfully worn. The white wool from the belly of the animal is still largely used in France for bonnets. The chinchilla (*chinchilla lanigera*) is an animal intermediate between the squirrel and the rabbit. It inhabits South American countries;

those producing the darkest and best colored skins (which are a silvery gray) are found among the Chilian Andes and in Arica. The fur is soft and delicate, and is principally consumed in France, Germany, and Russia. Bear skins, included in peltry, are of various sorts. The skins of the black bear (*ursus Americanus*) and grisly bear (*U. horribilis*) are used for military caps, housings, holsters, sleigh robes, &c.; the fur of the brown bear (*U. Isabellinus*) for articles of ladies' dress. The fisher is a North American animal of larger size than the sable, with longer and fuller fur. The most valuable of the fox skins are those of the black or silver fox. The latter are occasionally obtained in the country bordering Lake Superior, and are there valued at more than \$50 apiece. When highly dressed they are worth in the European markets from 10 to 40 guineas each. They are bought principally for the Russian and Chinese markets. The white fox (*vulpes lagopus*) is very abundant in the arctic regions. The skins of the red fox are purchased by the Chinese, Persians, Greeks, &c., and made into linings for robes, &c. They are

ornamented with the black fur of the paws, which is set on in spots or waves. The fiery fox is an Asiatic species of a brilliant red color and very fine fur. It is the standard of value on the N. E. coast of Asia. At the Leipsic fair it is known as the Podolian fox. The lynx includes the Canada lynx and the lynx cat (*Felis Canadensis* and *F. rufa*). The fur is soft, warm, and light, naturally of a grayish color, with dark spots, but commonly dyed a beautiful shining black. It is used for facings and linings of cloaks, for the most part in America, brought back from England. Several species, or at least varieties, of marten or sable produce the fur which is commonly known by the latter name. The most valuable is the crown or Russian, the skin of the *mustela sibirica*, the use of which in Russia is monopolized by the imperial family and nobility. The darker varieties have sold for £9 each, but their average value does not exceed £2 or £3. The use of this fur in the time of Henry VIII. was restricted to those above the rank of viscount. The lining of a robe of state, if made of the finest sables, is stated to cost sometimes 1,000 guineas. The best skins are obtained in Yakootsk, Kamchatka, and Russian Lapland. Only about 25,000 are annually procured, and but few of them reach the English market. Some are brought every year by Jewish traders to the fair at Leipsic, obtained privately from Siberia. In 1855 many choice furs were received in New York from the Russian American company at Sitka, it being thought more prudent to send them there than to risk their reaching St. Petersburg. Among the packages was a camphor wood box of about 3 feet in length, bearing the stamp of the Russian government, and containing 400 small skins, which were valued at \$14,000. The highest prized were those almost black, which were rated at \$51 or \$52 each. A cape of full size would require from 16 to 18 of these skins. The Hudson's bay sable were rated in 1856 at about \$25 per skin. The fur of the tails is an excellent material for the fine pencils or brushes used by artists. The Hudson's bay sable is generally considered another species, and is named *M. Canadensis*. The fur is commonly dyed a darker color than that natural to the animal. The chief demand for this fur is in England, France, and Germany. The baum or pine marten (*M. abietum*) and the stone marten (*M. saxorum*) are European sables, the former living in wild districts, the latter often near the habitations of man. The fur of the latter is much used by the French, who excel in dyeing it, and it is hence often known as French sable. The minx or mink (*M. vison*) is of the same genus with the other sables; the fur is largely obtained in North America, and is sometimes passed off as real Russian sable. The Kolinski is an inferior Russian or Tartar sable; the tail affords the best hairs for artists' pencils. The choicest fur of the sables is that of the ermine (*M. erminea*). This is a small animal only 10 or 12 inches in length, much resembling the common weasel, but differing from it in its

fur changing from a dingy brown to a pure white in the winter season in the cold regions of Russia, Sweden, and Norway, where alone it is found. The lower part of the tail is shining jet black, and this is commonly introduced as an ornament to the white fur, being inserted at intervals. The paws of the black Astrakhan lamb are often substituted for the tail of the ermine. This fur, called *minever* in heraldry, has been the royal fur of several European nations. Its use was restricted to the royal family of England by Edward III. At present it may be worn by any one; the modes of ornamenting it, however, as it is worn on state occasions, serve still to distinguish the sovereign and the rank of the peers, peeresses, judges, &c. Only the robes of the royal family can be trimmed with ermine thickly spotted with the black paws of the Astrakhan lamb. The use of the ermine fur is restricted in Austria to the imperial family; and it also distinguishes the sovereigns of Germany, Spain, Portugal, and Russia. The muskrat or musquash (*Fiber sibiricus*) is a common inhabitant of the banks of our streams, in the most remote districts of the mountains, as well as in the cultivated meadows around our villages. The fur is principally used by the hatters, who pay a small price for the skins. It is also dressed and used for the other uses of fur. The skins of the otter (*Lutra vulgaris*, *L. Canadensis*) make a beautiful and warm fur, which is much valued, especially by the Russians, Greeks, and Chinese. It is for the most part an American product; but it is also procured to some extent in the British isles from a smaller variety of the species. Another small variety with short fur is also found in the East Indies. The sea otter (*Enhydra marina*) is found in the north Pacific ocean, on the Asiatic and American coasts. Its habits resemble those of the seal. The Russians and Chinese highly esteem its fur, and it is said that its use in China is restricted to the emperor, mandarins, and officers of state. It was first introduced into commerce in 1725, and in 1780 it was in great demand in China, and commanded such prices, from \$30 to \$100 a skin, that several American and British expeditions were set on foot to obtain the furs on the northern islands of the Pacific, about Nootka sound, &c. Many varieties of the seal (*phoca*) furnish useful furs. The large supplies are from the coasts of cold countries. The fine silky and curly yellow down of this animal is disfigured in the natural state by long coarse hairs which grow through it, and are rooted deep in the pelt. These are removed by splitting the skins with a sharp blade between the roots of the two kinds of hair; the same effect occurs by a process of fermentation. The fur is usually dyed a deep brown color, and then resembles in its softness the richest velvet. Wolf skins are of little value for fur; they serve for sleigh robes and such purposes. The squirrel (*Sciurus vulgaris*), though diminutive in size, furnishes a vast amount of fur. The animal is found of many varieties in cold countries, and

the number of them destroyed is almost incredible. In Russia alone it is estimated that about 23,000,000 skins are annually obtained. The most valuable portion is the back of the gray squirrel; the white portion covering the belly is also highly prized, especially for cloak linings. The Weisenfels lining, weighing only 25 ounces, will cover a full-sized cloak. The tails are made into boas, and the hairs into artists' brushes. The fitch is the European polecat (*mustela putorius*). Its fur is perhaps more used in this country than in those to which it is indigenous. The various species of the rabbit and the hare furnish much fur that is used in making felt; and the skins of some of them are sufficiently strong to be dressed for linings, those of the Polish rabbit being now no mean substitute for ermine. The silver gray rabbit was formerly known only in Lincolnshire, England, but the breed is now raised in warrens in various parts of England, and the fur is exported to China and Russia, where it is much valued, though thought little of in its own country. The business of breeding rabbits for their fur has been introduced into the United States, and large numbers of them were raised not long since in warrens near Danbury, Conn. The nutria or coypou (*myopotamus coypus*), not included in the above table, formerly supplied large quantities of fur for hats, as many as 600,000 skins being exported to Great Britain annually from Buenos Ayres and Chili. The supply has now fallen off, and the few skins obtained are dressed as a substitute for the more costly fur seal. The fur of the North American wolverine or glutton (*gulo luscus*) finds a market for the most part in Germany, where it is used for cloak linings, &c. The skins of the skunk (*mephitis americana*) are annually exported from New York to the amount of many thousands, and from England they are reshipped to the continent. They are worth from 50 to 67 cts. apiece, the black ones being most esteemed. Valuable furs are supplied from many other animals beside those enumerated, as the badger, whose long wiry hairs are also used for shaving brushes. The domestic cat is bred in Holland for its fur, and the skins are merchantable in the United States, being worth from 10 to 50 cts. each; kittens 6 to 8 cts. Mention has been made of the paws of the black Astrakhan lamb. This animal is covered with the most rich and glossy silk-like fur, all the more delicate, it is said, when obtained, as is not unusual, by slaughtering the mother before the birth of the lamb. The fur of the Persian gray and black lambs is made the better to retain its curliness by the practice of sewing the animal tightly in leather immediately after its birth. The furs of the leopard, tiger, lion, &c., find uses as sleigh robes, mats, &c.—Notwithstanding the increasing scarcity of furs, what is called the fancy fur trade, being that in furs used principally for the dresses of ladies, and exclusive of hatters' furs and buffalo robes, is of growing importance in the United States. The wholesale and retail trade of the city of New York for the year 1856 was estimated at about

\$1,875,000. The increased demand was mostly for the skins of the mink and opossum, the effect of which has been to raise the price of the former from its old rate of from 30 to 50 cents each to from \$3 50 to \$4. Among the publications relating to furs and the fur trade may be mentioned a paper of Mr. Aiken, published in the "Transactions of the Society for the Encouragement of Arts, Manufactures, and Commerce" (London, 1830); Irving's "Astoria;" an article in the "American Journal of Science" (vol. xxv., 1834); and a "Report of the Celebration of the Anniversary of the Founding of St. Louis on the 15th day of February, A. D. 1847."—FUR-DRESSING. As skins are sent to market they have been commonly merely dried in the sun or by a fire; or possibly the small skins may have been first steeped in a solution of alum. The object is to render the pelt perfectly dry, so that when packed it shall not be liable to putrefy. When stored in large quantities the skins are carefully protected from dampness, and to secure them from injury by moths, they are strewed with camphor, and every few weeks are overhauled, and each skin beaten with a stick. This causes the worms of the moth to fall upon the floor, where they are immediately crushed. As the fur-dresser receives the skins he causes them to be subjected to different processes according to the kind of fur and the object for which it is intended. The fine qualities for ornamental dresses are usually placed in tubs together with a quantity of rancid butter, and are then trampled upon by the feet of men. The pelt thus becomes softened, as if partially tanned. They are next cleaned of the loose bits of integument by rubbing them with a strip of iron. The grease is then removed by trampling them again with a mixture of sawdust—that of mahogany is preferred—and occasionally beating them, and combing the fur. This is all that is necessary to prepare them for the cutter, whose office it is to cut out the variously shaped pieces, and sew them together to make the different articles. The cutting requires much skill to avoid waste. From a great number of similar skins parts of the same shades of color are selected, and thus each muff, mantle, or other article is made to present a uniform color. The seams are concealed by the lining with which the furs are finished.—Furs intended for felting, as the sorts used in hat making, are differently prepared. Hare skins are split open, then rubbed with a jagged knife blade called a rake to remove bits of fleshy matter adhering to the pelt. They are then damped on the pelt side with water, and being placed together in pairs, pelt to pelt, are pressed. They are thus made smooth and ready for shearing, an operation by which the long coarse hairs are clipped close down to the fur. The angular projections and edges of the pelt are then trimmed off, a process called rounding. The next operation is cutting off the fur. This is performed with broad knives, made it may be of sheet iron or of steel, frequently sharpened to a rough edge by rubbing them

upon a coarse whetstone. The skins are held upon a cutting board made of willow wood, and kept moistened with water, and the knife, applied first at the cheeks of the skin, is run rapidly forward and backward, steadily removing the fur as it progresses toward the tail. An instrument of tin is held in the left hand against the knife, and by means of this the fur is gathered up and kept in one fleece. By the old method the skins were split down the back, dividing them into halves, and in cutting one of these the left hand served without any instrument to press the knife forward and gather the fur in, being lifted for the purpose with every 2 or 3 strokes. Rabbit skins are treated in a similar way, except that the long hairs, instead of being clipped, are pulled by catching each one between a knife blade and the thumb, this being protected by a leather covering. Beaver and nutria skins require more care to remove the fatty and fleshy matters, and to cleanse them from grease, all which must be done before the long hairs are pulled. Nutria skins especially are loaded with fat upon the pelt, and the fur is filled with grease. Scrubbing with a brush and free use of soap and boiling water are necessary to remove the latter. The fur of beaver skins is cut by machines, which have been successfully applied to this thick kind of pelt; but the unevenness of other sorts prevents their application to these. Attempts have been made to remove the fur by chemical ingredients, but the effect of these has usually been to impair the felting property. But the application of dilute sulphuric acid to the fur before it is removed from the pelt is found to improve this property, probably by its destroying the last traces of the grease. Skins that have been wetted with it are said to be caroted, from the color it imparts; they should be immediately dried by exposure to the heat of a fire, or by smoothing with a hot iron and drying in the sun. Rabbit and hare skins by long keeping are very liable to suffer injury from moths and other insects, and the former, especially if kept in large heaps, from the running of the greasy matter among them, and becoming rancid, corroding the pelt itself. In England it is found that the strongest rabbit fur for felting is obtained from animals bred near the sea, particularly along the coast of Lincolnshire and Berwick and the intermediate coast. The skins taken in the winter are far superior in quality to those obtained at other times, and are distinguished in the trade as seasoned, all others being called unseasoned.—For further information in this department of the fur manufacture see FELT, and HAT.

FUREEDPOOR, or **DACCA JELALPOOR**, a district of British India, presidency of Bengal, bounded N. by Mynumsing, E. by Dacca, S. by Backergunge, and W. by Jessore and Pubna; area, 2,052 sq. m.; pop. 855,000. It is wholly alluvial, and in the S. and N. E. parts, where the land is low and marshy, is subject to frequent inundations, but the N. and N. W. are more elevated, and have a rich, deep soil. The Ganges

touches the W. frontier at Juffergunge, and receives an offset of the Konaia, by which its volume is more than doubled; 15 m. below it enters the district, which it waters for 60 m. of its course, sending off near the E. frontier a branch called the Kirtynassa, which connects it with the Brahmapootra. The principal productions of the district are the sugar cane, cotton, indigo, oil seeds, and rice. Among the manufactures are indigo, sugar, rum, and coarse cotton cloths for domestic use. Fureedpoor, Hobbigunge, and Juffergunge are the chief towns. The district was acquired by a grant from the emperor Shah Alum in 1765.—**FUREEDPOOR**, the capital of the above district, is a straggling town on the right bank of the Ganges, here called the Podda, 115 m. N. E. from Calcutta. It was formerly notorious as a resort of river pirates, but since the establishment of the government officers at this place the evil has been abated.

FURETIÈRE, **ANTOINE**, a French author chiefly known for his controversy with the academy, born in Paris in 1620, died May 14, 1688. He was successively an advocate, a fiscal agent, an abbé, and a prior, and was admitted into the French academy in 1662. While the academy was preparing its dictionary, Furetière, regarding the work as defective, determined to edit and publish a lexicon on his own account. Hence the academy excluded him, and a war of epigrams, satires, and libels, unsurpassed for violence, began between him and the leading academicians. Furetière was protected by the most important personages, by Racine, Boileau, Molière, Bossuet, and even Louis XIV., and his wit and vivacity distinguished him in society; but his death occurred before the suit which he prosecuted against the academy was decided. His dictionary, enlarged by Basnage, passed through several editions. He wrote also a few fables and poems.

FURIES. See **EUMENIDES**.

FURLONG (Sax. *far* or *fur* and *long*), an old English measure of 40 poles, equivalent to $\frac{1}{4}$ of a mile. In Ireland it is 0.15 of a mile, and in Scotland 0.1409. In the United States the measure is not in use. As a superficial measure, a furlong in Great Britain is generally 10 acres, according to the acre of different counties; but it was formerly used for a piece of land of no particular dimensions.

FURNACE (Lat. *forneas*), a structure containing a fireplace, intended for maintaining intense heat. It differs from a kiln, which is used for purposes requiring lower degrees of heat, the one being contrived to effect rapid combustion, and the other to sustain a slowly consuming fire. In many of the useful arts the first requisite is the means of obtaining a very high temperature. In all metallurgic operations, the object of which is the reduction of the ores and treatment of the metals, and in almost every art involving the use of fire, a furnace of some kind for producing this heat is in demand. The ancient Greeks employed furnaces for casting statues of bronze; Homer makes mention of a

blast furnace with 20 crucibles (Pl. xviii. 470). The Egyptians are known to have made use of melting pots, but we have no knowledge of their furnaces. An ancient smelting furnace was discovered near Arles, in southern France, which was shaped like an inverted bell, having under the surface of the ground a channel for the discharge of the melted metal. Strabo speaks of furnaces built in Spain, which were raised to a great height for conveying off the noxious fumes. They were also furnished with long flues and chambers made for collecting the oxides and other sublimed matters. The forms and dimensions of modern furnaces vary greatly according to the different purposes they are designed to serve. The iron manufacturer, smelting the ores upon the vast scale upon which his business is conducted, builds an immense structure with a capacity of hundreds of tons, and furnishes it with heavy machinery for supplying the great volume of air blown in almost without ceasing, as the operation is continued during a single "blast" of two years or more. But the furnace which first tries his ores and determines their properties, in order to guide the workings of the great establishment, may be but a small vessel of refractory material, heated in the laboratory by a gas flame, made more intense by its mixture with a current of atmospheric air. (See BLOWPIPE.) In the article COPPER SMELTING, reference has been made to the peculiar furnaces employed in this operation; and those made use of in the treatment of iron ores will be described in the article upon that metal. Other furnaces also will be found noticed in the accounts of the arts to which they belong, and those for warming buildings in the article on WARMING AND VENTILATION.—All furnaces employed in melting refractory materials—those for assaying, as well as those operating upon a large scale—require a free supply of air, proportional in quantity to the amount of fuel they consume. The generation of heat depends upon the rapid chemical combination of carbon with oxygen, and a sufficient supply of the latter element is as essential as is that of the former. Every pound of good bituminous coal, according to Dr. Thomson, requires 150 cubic feet of air, or, allowing $\frac{1}{2}$ more for waste, there should be supplied at least 200 cubic feet. So immense is the quantity of this invisible element consumed and wasted in the large furnaces for smelting iron ores, that its weight even is greater than that of all the other materials, ores, coal, and flux, introduced; and the power required to force this volume of air through the dense column of heated matters far exceeds that expended in charging the furnace with its solid contents, even adding to this the power involved in the removal of the products of the operation. To provide for this large supply is then a matter of the first consequence to furnaces; and according to the mode in which this is effected they are separated into two classes. The kind called air or wind or reverberatory furnaces receive their supply by means of the

current produced by a tall chimney, the heated column rushing upward through the flue, as a Montgolfier balloon rises when the air within it is rarefied and rendered specifically lighter by heat. (See CHIMNEY.) To fill the space in the lower part of the flue, air presses in from without through every aperture; and none being allowed except those leading through the receptacle for the fuel, the supply of air is thus secured, heat is generated for the purposes required, and a portion is expended in furnishing the mechanical power involved in the movement of the current of air. Our fireplaces, stoves, and grates are examples of air furnaces; and by means of the blower, which causes the air admitted into the chimney to pass first through the fire, the flue is prevented from becoming chilled by the entrance of cold air, the column ascends more rapidly, an increased supply of air is furnished to every portion of the body of fuel, and the chemical process goes on with augmented intensity and generation of heat. The other classes of furnaces are supplied with air through bellows or other blowing apparatus. (See BLOWING MACHINES.) They are called for this reason blast furnaces, and are used when the resistance opposed to the passage of the current of air by the density of the contents of the furnace is so great, that sufficient quantity cannot penetrate to keep up thorough combustion throughout the mass; or when the operations do not admit of the large openings beneath the fire, which the free admission of such bodies of air would require; or again, when the nature of the operation demands an intensity of heat concentrated in one spot. The blast in this case acts like the jet of the blowpipe, and its effect is in many cases greatly increased by its being conveyed through iron pipes which are highly heated by exposure in suitable ovens to the waste heat of the smoke and gases which escape from the chimney. It thus returns to the interior of the furnace, in the form of highly heated air, a portion of the caloric that would otherwise be lost. Furnaces of both classes are often used in the chemical laboratory. The one commonly employed for general purposes is a wind furnace, built of fire brick, and strongly secured with iron rods and straps. It has a flat top, with two or more openings, and on these are placed pans of cast iron, one exposing a surface of 2 to 8 feet square running over the flue. This contains the sand in which vessels are placed for exposure to moderate heat. The other is a deeper pan or rather pot, also partially filled with sand, in which retorts and other vessels may be subjected to more intense heat. The furnace has under the flue that leads into the chimney an oven for drying. With a good draught this furnace produces sufficient heat for many crucible operations. These are, however, better conducted in smaller furnaces, either wind or blast, constructed specially for this use. Dr. Faraday contrived a very simple one of the latter class, which he used in the laboratory of the royal institution. He employed two blue-

pots or plumbago crucibles, one 18 inches high and 18 inches diameter at top, and another introduced into this as a lining, $7\frac{1}{4}$ inches diameter inside, from which the bottom had been removed, leaving an opening of 5 inches. A space was left between the two pots at top, which he filled and packed with powdered glass-blowers' pots, moistened with water. A round iron grate was then set near the bottom of the inner pot, and a hole to receive exactly the nozzle of a double bellows was drilled at the base of the outer one through this into the space beneath the grate. By blowing in air the fire of coke upon the grate was made to burn with great intensity, so that pieces of bar iron could be melted in crucibles within 15 minutes. A wind furnace of great power adapted for crucible operations and cupelling also, referred to at the close of the article DENTISTRY, was contrived and manufactured by Dr. E. A. L. Roberts of New York, originally only for processes connected with the making of mineral teeth. The portion above the grates is formed of slabs of fire brick shaped for the purpose, one for each side, and one for the top. When put together they form a truncated pyramidal figure, whose greatest inside capacity is 12×14 inches. Suitable openings are left in these, one in the top for the smoke flue, one in the side for supplying fuel, which is closed with a fire brick plug, and in the larger furnaces 3 in front, one just above the grates and 2 above this for muffles. The upper 2 are used for annealing and for partial baking. The smaller furnaces have but one opening for muffles. These are made of the form of a triangular prism, with the corners rounded and made thicker than in the ordinary muffles, these being the weak points that usually first give out. The whole is strongly bound with iron. The base of the furnace is a cast iron box, open at top, with a horizontal flange projecting like the rim of a hat on the two opposite sides, upon which the upper portion is set. Two grates are laid in the top of the cast iron box, supported on pivots at the outer corners, so that each may, when desired, be dropped flat against its side of the box. Along a line from front to back through the middle of the furnace is fixed a turning bar, which supports the inner edges of the two grates at such a height that each slopes from the outer edge toward the centre at an angle of about 80° with the horizon. By turning the bar the grates may be made to discharge a part or the whole of the ashes and cinders. The front and back fire brick plates of the upper portion are shaped to fit the slopes of the grates. Under the grates are the usual doors for admitting air and affording access to remove the ashes. In baking mineral teeth, a process requiring intense white heat, it is found that with this furnace an effect may be obtained in 15 minutes which requires from 20 to 25 minutes by the ordinary furnaces.

FURNESS, WILLIAM HENRY, D.D., an American clergyman and author, born in Boston,

Mass., April 20, 1802. He studied at the Boston Latin school, was graduated at Harvard college in 1820, completed his theological course at Cambridge in 1823, and was ordained pastor of the First Congregational Unitarian church in Philadelphia in Jan. 1825. One of his constant labors as a preacher and author has been to ascertain the historical truth and develop the spiritual ideas of the records of the life of Christ. To this end he has published "Remarks on the Four Gospels" (Philadelphia, 1836; London, 1836 and 1851); "Jesus and his Biographers" (8vo., Philadelphia, 1838); a "History of Jesus" (1850; new ed., Boston, 1853); and "Thoughts on the Life and Character of Jesus of Nazareth" (Boston, 1859). These works reveal a highly cultivated intellect, impelled by enthusiastic ardor and enriched by a glowing fancy, and present a peculiar humanitarian view of the character of Christ. "Æsthetic considerations," says a writer of his own denomination, "weigh more with him than historical proofs, and vividness of conception than demonstration." Dr. Furness has published a volume of prayers, entitled "Domestic Worship" (2d ed., Boston, 1850), and a volume of discourses (Philadelphia, 1855). He has also written hymns and other devotional pieces in verse, and has made exquisite translations from the German, among which are the "Mirror of Nature" from Schubert, the "Song of the Bell" from Schiller, a volume of "Gems of German Verse," an enlarged edition of which is now (Aug. 1859) in the press, and a volume entitled "Julius, and other Tales, from the German" (Philadelphia, 1856). He edited for 8 years the "Diadem," a Philadelphia annual, has contributed a few articles to the "Christian Examiner" of Boston, and is the author of a large number of published occasional sermons, many of which are in support of the anti-slavery movement, in which he takes deep interest. His latest published discourse (1859) is on the "Right of Property in Man." He is the pastor of a large and intelligent society, and as a preacher is eminent for the earnest and eloquent presentation of his individual convictions.

FURNITURE, articles and utensils used in housekeeping. As in all countries wood is the chief material employed for furniture, we are necessarily destitute of ancient examples, and for remote times are obliged to rely on the representations given by monuments still extant. The ancient Egyptians, in the arrangements of their rooms and the character of the furniture, studied variety; neither the windows, doors, nor wings of a house exactly corresponded with each other. They sat on chairs like Europeans, and the great variety and elegance of these articles is remarkable; they were formed of ebony and other rare woods, often inlaid with ivory and gold and covered with costly tissues. Stools and low seats were also used; settees on the principle of the modern camp stool were found in every house, the folding seat covered with the skin of a leopard; the seats of chairs

were also frequently made of interlaced thongs or strings, exactly similar to our Indian cane chairs. Carpets were in use; a single specimen indeed exists—a small rug made with woollen threads on linen strings, with ornaments in blue and red on a yellow ground. Square sofas, or ottomans, with leathern cushions and painted bases, and elegant couches with one end raised and receding in a graceful curve, the feet fashioned to resemble those of a wild animal, were also among the usual fittings of a room. The tables were round, square, or oblong, those of the first shape being often supported by a single shaft or leg in the centre carved to represent a human captive. Of their bedroom furniture we have little knowledge. They seem to have used a kind of wicker bedstead of palm branches, not unlike the framework on which their descendants at the present day rest their mattresses and divans, and the wealthier classes also used bedsteads of iron, and perhaps of bronze. They had mirrors of burnished metal, chiefly of copper, with ornamented handles. It is uncertain of what material they made their lamps. The flame was sustained by a floating wick, and fed with salt and oil. Among the kitchen utensils were caldrons for boiling meat, tripods and metal frames for supporting them over the fire, bellows worked by the feet, siphons for drawing off liquids, and a stand or table equivalent to the modern dresser. Neither knives nor forks were used in eating, but spoons and ladles were employed, and the large joints of meat may have been carved with a knife. The great variety of vases of different material in every house served both for use and ornament. Those intended for the former were of glazed earthenware or vitrified pottery, often of elegant design; but in the richer specimens intended for sacred purposes or as purely decorative objects, the most costly materials were employed. They were of gold or silver, alabaster, porcelain, or richly colored glass, the last with elaborate patterns fused together, in a manner which the skill of modern glass workers is insufficient to explain. The thousand little elegances testifying to the benign effect of female presence were always to be found in Egyptian rooms, as their women were not secluded, but mingled freely in the dinner parties and reunions that were a prominent feature of the social arrangements of the people. In short, "hushed old Egypt" was a land where great comfort and luxury were enjoyed, and there is scarcely an article of our daily use that cannot be paralleled by an example (in most cases superior in design) from the monumental remains of the ancient Egyptians.—The Assyrians, unlike the Egyptians, whose monumental records abound with details of a domestic character, seem to have found their chief delight in the incidents of war and in the adventures of its peaceful rival the chase. Still evidence relating to the private life of the people can be collected from the sculptures, and we have even the additional confirmation of the remains themselves. We

can reproduce from the relics before us the throne of Sennacherib, rich in metallic chasings and ivory carvings. We can enter his treasure chamber, and separate from the half calcined mass the fragments of "shields, swords, patera, bowls, crowns, caldrons, mother-of-pearl ornaments," &c., that once formed a part of Assyrian magnificence. The forms of household articles of furniture all show great artistic elaboration and a profusion of highly wrought ornament, which is also lavished on dresses, arms, and utensils of all kinds. Couches, chairs of state, tables, stools, and chariots are all marked by this abundance of ornamental detail. Much of this was executed in metal, and specimens enough remain to show the skill of the Assyrians in the various processes of chasing, casting, and hammering out the copper that they procured from the mountains to the north of Mesopotamia. A fierce, haughty, and conquering people, their character is reproduced on their monuments; their delight in the chase seems to have given them a fondness for the forms of animal life, lions' feet, the heads of leopards, &c., being used in decorating furniture and arms, as employed in the present day. The representations of banquets show that tables and chairs were in use. A unique bass-relief introduces to the interior of the king's kitchen; here in one compartment is seen the preparation of the carcasses of animals for cooking, while in others the eunuchs preside over a brazier of elegant form supporting vases used for stewing, &c., and heated by charcoal.—There is no question that Assyrian art through the Asiatic Ionians was the source whence the Greeks derived their first ideas of æsthetic achievements; but whatever they borrowed soon became their own through the transforming influence of an organization and culture which have never been possessed in equal measure by any other people. In the best days of Greece every thing tended to merge the individuality of the citizen in the state of which he was a constituent part; consequently the accessories of domestic life were not regarded as of the same importance as in more despotic countries. Splendor was lavished on the temples and public buildings, not on private structures. The Athenian houses, even in the time of Pericles, were neither large nor stately. For repose, the Greeks had couches, covered with skins or drapery, on which several persons might lie with their bodies half raised; these were used at meal times by the men only, women and children sitting always on chairs; also large arm chairs with footstools, portable small chairs without arms, and stools with curved legs made to fold up. Tripods of marble or metal were in great request for religious and domestic purposes, as well as candelabra and lamps, either supported on a base or suspended from a chain. For the forms of these and other articles, in the absence of any existing remains, we have ample authority in the designs on the so called Etruscan vases. In reality these were the work of Grecian artists in the colonial cities

of Magna Græcia or in Attica itself. They furnish an inexhaustible magazine of the purest ornamental detail, and show how the most trifling objects were conformed to the true principles of the beautiful. Rejecting the animal forms of the Asiatics, the enrichments were derived from a conventional treatment of the most elegant examples of the vegetable kingdom—the acanthus, the honeysuckle, the olive, &c., supplying the “motive” of designs that the eye of taste is never weary of. Endless was the variety of these vases for religious rites or domestic purposes. In them we have an instance of every kind of beauty and elegance of outline that can give value to the humblest material. The immense number still existing of these fragile articles shows how general the use of them must have been.—Among the Romans Greek art still retained its predominance, and the conquerors of the world were at all times glad to employ natives of Greece to design and execute the works intended to display the opulence of their masters. On the ornaments of the *triclinia* or couches on which they reposed immense sums were bestowed. They were often inlaid with precious materials, such as ivory, tortoise shell, gold, and silver, and had ivory or metal feet. They consisted of a framework, sometimes of wood, which was strung with girths upon which rested a mattress stuffed with straw, wool, or feathers, and covered with rich drapery. The *lectus cubicularis*, or bed, was higher than the couch, but not unlike it. The tables were generally of costly foreign wood resting on frames of carved marble or an ivory column. The curule chairs, or seats of state of the patricians, were wrought in ivory; and to form an estimate from the number of beautiful utensils in marble and bronze richly chased and inlaid with silver that have been found in the ruins of a comparatively insignificant city, Pompeii, the wealth of the Romans in movable property of this nature was very great. The library first appears as a separate apartment in a Roman house; that discovered at Herculaneum was small, and lined with presses about the height of a man, in which the rolls of papyrus and parchment were kept. Still, according to modern ideas, the Roman rooms would seem rather bare of furniture. They had no writing tables, or cabinets; couches, chairs, tables, and candelabra comprised the whole of the furniture, with the exception now and then of a water clock, or a chafing dish of coals, in a bronze tripod in winter. The beautiful restoration of a Roman house by Italian artists in the crystal palace at Sydenham, and the Roman villa of Prince Napoleon at Paris, are the chief attempts in modern times to reproduce the effect of a classical interior. Many of the ornamental articles in bronze designed from the antique for the latter are to be found among the latest Parisian importations in our shops.—Until the reformation the development of civilization among the Christian states of Europe took the same forms, and proceeded at nearly an

equal rate. They were in fact in their higher relations portions of a great ecclesiastical commonwealth with a visible and external head. From A. D. 500 to 1500, the ecclesiastical style prevails in furniture as well as in every other species of art, attaining its greatest eminence in the decorated Gothic of the 14th century. Articles of furniture previous to 1500 are of the greatest rarity, and the few specimens that remain occur in connection with ecclesiastical affairs, as the table in Salisbury cathedral on which the wages of the builders were counted out, the abbot of Evesham's conventual chair, the coronation chair of the kings of England, of the time of Edward I., in Westminster abbey, &c. We are therefore obliged to have recourse to the illuminations of MSS. of the middle ages for more familiar details. For 8 centuries after the conquest domestic furniture was very scanty. A bed and a chest were the chief appendages of our forefathers' bedrooms, in the Anglo-Norman era, and tables and benches of the hall. Beds are seldom represented with curtains or canopies, and the chest served the purpose of a wardrobe. The floors were usually of wood, strewn with dried rushes in winter and green fodder in summer. There were no “furniture emporiums;” every article needed was made on the spot by a carpenter. Chairs were large and cumbersome, and were usually fixtures; wooden forms, sometimes with back rails, being placed against the walls. Carpets were first introduced in England by Eleanor of Castile, wife of Edward I., but were not generally used until the 15th century. The furniture of the dining room was very limited. Boards on trestles were in general use as tables; the huge salt cellar was the chief ornament of the board. At royal and noble tables silver goblets, plates, and dishes were seen, but in ordinary houses wooden bowls and trenchers only were used. Earthen ware, though made in the form of pitchers and jugs, does not seem to have been applied to the fabrication of plates and dishes; indeed, in remote parts of England and in institutions famed for conservatism (as the colleges and public schools), the square wooden trencher board, the pewter dishes, and the leathern “black jack” for holding beer, are scarcely yet out of use. A constant current of change in the direction of improvement was in motion during the middle ages, and from these rude beginnings in the 14th and 15th centuries a remarkable progress was made, and a considerable degree of splendor was attained. Defence began to be not the only object studied in the construction of buildings. The apartments expanded in height, and were hung with the newly invented tapestry of the Netherlands (the workshop and exchange of mediæval Europe), called “Arras” from the place of its origin. The Gothic panelling of the carved bedsteads, chairs, screens, &c., was dazzling with scarlet, blue, and gold, and costly embroidered hangings and curtains heavy with heraldic symbolism, cabinets, reading desks, prie-dieus, ivory and enamelled coffers, fire

dogs or andirons elaborately chased and gilt, began to appear, all harmonized to a rich glow of color by the gemmed and jewelled light that stole through the mullions of the storied windows of "bower and hall." The further progress of this decorative style was suddenly arrested by what is called the "renaissance," or revival of ancient classical art and literature, of which Italy was the earliest seat, and from whence the impulse was given that communicated itself speedily to the rest of Europe. Italy indeed occupied then the position now held by France, fabricating and designing most of the costly objects of art and luxury that began to be sought for in remote countries, with the increase of wealth. A genuine and self-evolved style instantly went out of fashion, and was discarded for an imitation and counterfeit one based on the copying of ill-understood classic models, which were applied without consideration to the most incongruous objects. The classical temple was the dominant idea in the manufacture of furniture, as well as in the construction of a palace or a cathedral, and columns were considered as necessary in one species of art as in the other. All the architectural details of Roman building were then applied to furniture; the lions, griffins, chimeras, &c., of the temple frieze encumbered the stately pillars of the Italian palaces, and caryatides and Roman trophies replaced the patron saint and the crucifix. With all its absurdities, it must be noted that this style was in the hands of great men, and their productions display a boldness and vigor of line and a mastery over human and animal forms that give dignity to a licentious freedom of design in which all appropriateness is forgotten. Specimens of the renaissance are still met with, though daily increasing in value. The remarkable collection formed by M. Soulagès of Toulouse of decorative works of this era in marble, metals, earthenware, &c., consists chiefly of articles of household use of Italian design, such as chimney-pieces, cabinets, and candelabra. It was purchased by some English gentlemen in 1856 for about \$120,000, and formed a chief attraction of the great exhibition of the fine arts at Manchester in 1857. The reign of Henry VIII. coincides with the introduction of this new style, whose effect is visible in our present domestic arrangements, Gothic art never having recovered its lost ground. Various articles now of daily use were introduced about this time. Chamber clocks began to be part of the usual furniture of a room. The famous one of silver gilt, designed by Holbein, and presented by Henry VIII. to Anne Boleyn, was purchased by the queen at the sale of Horace Walpole's effects at Strawberry Hill for \$500, and is now at Windsor. The oldest clock that is supposed to go tolerably now in England is at Hampton Court, of the date of 1540. Looking glasses or mirrors were now made in Italy, to be suspended on the walls of rooms, and were among the most costly articles of furni-

ture. A little later musical instruments, both a species of hand organ and the virginals, the earliest form of the modern harpsichord, appear. With various modifications the renaissance style continued dominant for nearly two centuries. In England it degenerated into positive ugliness, the furniture of the time of Elizabeth and James I. having very little to recommend it in tasteful design. It is distinguished by a mixture of overwrought, heavy moulding, combined with thin spindly columns, twisted legs, and other inelegant characteristics. Magnificence is sometimes attempted in the value of the material, as in the famous set of chamber furniture in chased silver executed for a royal visit at Knowle Park, the seat of the dukes of Dorset in Kent. It was succeeded by the style named after the French monarch, its patron and encourager, Louis XIV.—The modern predominance of France in the construction of furniture is owing to the minister Colbert. He it was who brought together the best workmen of Europe, and by an edict of the year 1667 established the French royal manufactory of furniture. The new style which the productions of this establishment assumed appears to have been worked out undesignedly, and, like every such successful phase of art, was the genuine product of circumstances. Novelty and magnificence seem to have been the great features aimed at; these were sought by varied treatment of surface in cabinet furniture (as inlays of metals, ivory, enamels, porcelain tablets, tortoise shell, &c.), and by an incrustation of broken scroll panel work which hid the real constructive forms and frittered away the graceful outlines of the renaissance into a confused and unsymmetrical mass. The famous artist, André Charles Boulle, who has given his name to the inlaid silver, brass, and tortoise shell style known as "Buhl work," was at the head of the royal manufactory with the title of *tapisier en titre du roi*. Under Louis XV. the same school of art continued, and it received new elaboration under the successors of Boulle, Riesner and Gouthier; their works are known to connoisseurs as articles of vertu by the respective styles of each master, and fine specimens bring almost fabulous prices in France. Probably more are to be found in Great Britain than in all the rest of Europe, the French revolution having exerted a fearful influence in bringing about a change of owners of costly movables. One of the finest and earliest specimens of Buhl work known is a secretaire or writing table made for the family of De Retz, now at Windsor, where is also the magnificent cabinet in ormolu and satin wood made in 1780 for the count d'Artois. A grand secretaire in marqueterie, made by Riesner, the *ébéniste de Louis XVI.*, for the dramatist Beaumarchais, at a cost of 85,000 francs, was disposed of by lottery in Paris in 1831, and now belongs to the duke of Buccleuch. At Northumberland house is one of the most precious cabinets in *pietra dura* in Europe, "a truly royal piece," with

the royal crown and cipher, executed in Italy for Louis XIV., and inlaid with precious stones, agates, jaspers, lapis lazuli, the natural colors of which are made to represent birds, flowers, butterflies, &c. While the splendid extravagances of Louis XIV. were holding sway in France, the prevailing taste in England seems rather to have been modified by the fashion introduced from Holland by William III. The native woods, oak or wainscot, chestnut, &c., were about this time superseded for furniture by the dark and heavy West India mahogany, the invariable material of the ill-designed and awkward furniture familiar to us in the immortal designs of Hogarth, and visible here and there in this country in the cherished relics of "colonial times." The prevailing degradation of taste was further visible in the passion for Chinese dragons and porcelain monstrosities, which were the favorite ornamental objects of the time. In the latter part of the reign of Louis XVI. another change is apparent in French furniture. Greece and Rome were looked up to as standards of correctness in furniture as well as in politics. Instead of impressing their own genius on the application of ancient models, as did the great artists of the renaissance, the authors of this revival were content with frigid imitation, and looked rather to Greece than to Italy for their originals. It was encouraged by the emperor Napoleon, who enlisted the genius of his architects Percier and Fontaine in this cause; while in England a similar movement was due to the cultivated taste of Mr. Thomas Hope, who recommended the ancient models for imitation in his work, "Household Furniture and Internal Decorations" (1807), and exemplified his own precepts in his classical mansion and gallery in London. In neither country was the classical style long successful, and since that time the practice of both France and England (and with them the rest of Europe) has been purely eclectic, no new style being introduced and no old one superseding all the others; but at the will of employers workmen are ready to execute designs of every age. A general prevalence of the taste for mediæval objects since 1830 is the most noticeable feature, and has shown itself extensively in building, painting, and decorating; but modern attempts in this style have been very unfortunate, though few of their authors would have the candor of A. W. Pugin, who says, in his "True Principles of Pointed Architecture," speaking of modern Gothic furniture: "We find diminutive flying buttresses about an arm chair; every thing is crocketed, with innumerable mitres, sharp ornaments, and turreted extremities. A man who remains any length of time in a modern Gothic room and escapes being wounded by some of its minutæ may consider himself extremely fortunate. I have perpetrated many of these enormities in the furniture I designed for Windsor castle, as at that time I had not the least idea of the true principles to be followed." If any style can be considered the favorite one in the United States,

it is a bastard Louis Quatorze, with all its characteristic failings carried to excess in design, though the workmanship of articles in ordinary use is very good. The English claim the merit of the best material and excellent workmanship; they confess that the artistic education of the French artisans gives them a superiority in design that they can hardly hope to equal.—In France the manufacture of furniture has become an important source of national wealth. Its chief seat is Paris; in 1855 from 25,000 to 30,000 workmen were employed in the various processes, and the value of the products was estimated at about \$18,000,000. In America a large proportion of the workmen are Germans, who have impressed some of the characteristic heaviness of their taste on the articles produced for common use. The higher class specimens are all executed from French designs. The finer qualities of mahogany have been getting scarce since the loss of the supplies formerly obtained from Hayti. It was succeeded in public favor by rosewood, a beautiful wood from South America and the West Indies; this has in its turn been superseded by the native black walnut, which by peculiar treatment is made susceptible of the finest polish, and is admirably adapted for the display of carved work. Among American inventions may be mentioned what is technically called "knock-down furniture;" the name is applied to complete sets of furniture, which are made to come entirely apart, so as to pack for transport to the West, &c., in a very small compass. The chair manufacture is a branch pursued to a great extent in Massachusetts, where the town of Gardner is largely engaged in it. Not a ship leaves with an assorted cargo for South America and the East Indies without having on board American boxed chairs in dozen and half dozen cases. Thousands of dozens are thus annually exported, and this demand always continues. They are turned by steam power from the maple, beech, and other hard woods, the only foreign article employed being the Indian ratan, which is split by machinery for the seating.

FURRUCKABAD, a district of British India, in the province of Agra, bounded N. by the districts of Budaon and Shahjehanpore, E. by the territory of Oude, S. and W. by the districts of Etawah, Cawnpore, and Mynpooree; area, 1,909 sq. m.; pop. 1,064,607, mostly Hindoos. The soil is of various quality. Much of that on the banks of the Ganges is deep, rich, and marshy, and in the rainy season is scarcely habitable. The central region is fertile, while the southern parts are thickly wooded. The principal productions are indigo, cotton, wheat, barley, maize, sugar cane, timber, and tobacco. In 1802 the E. I. company took possession of this district, pensioned its nabob, and annexed it to the Bengal presidency.—FURRUCKABAD, the chief town of the district, is situated near the right bank of the Ganges; pop. 56,800. The trade is considerable. Here was formerly a mint, the coinage of which

circulated largely throughout the N. W. provinces. It was abolished in 1824.

FÜRST, JUDAS, a German orientalist of Jewish race, born in Zerkowa, in the duchy of Posen, May 12, 1805, studied at Posen and Breslau, and in 1833 became teacher (*Docent*) of the oriental languages. His historical, grammatical, and lexicographical works are numerous and valuable; the principal of them are a "System of the Aramaic Idioms" (1835); *Concordantia Librorum Sacrorum V. T. Hebraica et Chaldaica* (Leipsic, 1837 *et seq.*); "Hebrew and Chaldean Dictionary for Schools" (1842); "Religious Philosophy of the Jews in the Middle Ages" (1845); "History of the Jews in Asia" (1849 *et seq.*); *Bibliotheca Judaica* (3 vols, 1849-'53); "Manual Dictionary of the Hebrew and Chaldean Languages" (1851 *et seq.*). From 1840 to 1851 he edited the "Orient."

FÜRTH, a town of Bavaria, in the province of Middle Franconia, situated at the confluence of the Rednitz and Pregnitz rivers, $4\frac{1}{2}$ m. by rail from Nuremberg; pop. 16,000. This railway, opened in 1835, was the first in Germany, and now extends from Frankfort to Munich. About 3,000 of the population are Jews, who have a high or Talmud school, 3 minor schools, several synagogues, 2 printing houses, a religious and civil court of justice, a hospital, and an institution for orphans and for the employment of their poor.

FUSE, SAFETY, a tubular cord of cotton, rendered slowly combustible for communicating fire to the powder in blasting. The cavity in the centre of the cord is filled with some slow-burning powder, and the cord is then wound with tarred twine, and covered outside with a coating of tar. It is thus protected from moisture, and is made sufficiently firm and hard not to be cut by the fragments used in tamping. It is either "double" or "single," the former being protected with an extra quantity of tarred covering, so that it can be used for exploding the cartridges used in wet holes. The latter, being only about half the price, is commonly used in dry blasting. It burns about 8 feet in a minute. A method has been patented of introducing a combustible thread through the centre of the cord in the powder, with the view of providing another means of communicating the fire in case the powder is interrupted or the cotton of the tube does not continue to burn. For its use, see BLASTING.

FUSEL OIL, a liquid colorless when pure, of offensive smell and burning taste, obtained by continuing the distillation of the fermented infusions used for the preparation of ardent spirits after the alcoholic portion has been drawn off. In this condition, however, it is mixed with water, from which it should be separated by a second distillation, the water coming over first. As this brings with it a portion of oil, it is to be set aside for the latter to separate, and form a layer on the surface. Ardent spirits contain fused oil, particularly if the distillation has been pushed far. It is detected by redistilling whis-

key, especially that obtained from potatoes, a milky fluid coming over at the last, from which the oil separates by standing; or by redistillation, water first coming over, and then the oil at its boiling point of 269° . Thus obtained, it is usually of a pale yellow, of specific gravity 0.818; at 4° below zero it congeals in crystalline leaves. It inflames only when heated to 130° . It unites with alcohol in all proportions, but has little affinity for water. The resins, fats, camphor, sulphur, phosphorus, &c., are dissolved by it. Upon the animal system it acts as an irritant poison; its vapor produces nausea, headache, and giddiness. Its composition is represented by the formula $C_{10}H_{12}O_2$; or, on the supposition of its being a hydrated oxide of amyle, its formula is $C_{10}H_{11}O, HO$. Fusel oil is used to some extent for burning in lamps, and for dissolving copal and other resins for varnishes, &c. Its presence is highly injurious to liquors, and when in sufficient quantity to be perceptible to the smell and taste, indicates bad rectification or the use of damaged grain. It may be detected by agitating the liquor with water, and leaving it to stand for the oil to rise and appear at the surface. It is separated in rectifying by the introduction of some soft wood charcoal, as pine or willow. Olive oil also may be added, and the mixture being well shaken the oils will afterward collect together at the surface, when they may be decanted and the spirits be again distilled.

FUSELI, HENRY, a painter and writer on art, born in Zürich, Switzerland, Feb. 7, 1741, died in London, April 16, 1825. His father was John Casper Füssli, also a painter. Having been destined for the church, he received a good classical education at his native town, and in 1761 took orders; but his predilection for his father's art had led him from childhood to cultivate it in secret, notwithstanding the parental prohibition. A pamphlet written by himself and Lavater, who was his schoolfellow, in which a public functionary was severely handled, was the cause of his leaving Zürich, and after spending some time in Vienna and Berlin he went to England, where for a time he supported himself by literary labors. Sir Joshua Reynolds, to whom he showed some of his drawings, advised him to devote himself to art, and he accordingly spent 8 years in Italy among the works of the old masters. Here he changed his name to its Italian form, which he ever after retained. Returning to England in 1778, he executed a number of pictures for Alderman Boydell's celebrated "Shakespeare Gallery." In 1790 he was elected an academician, and in 1799 he exhibited a series of 47 designs on a large scale from Milton's works. In the same year he became professor of painting in the academy. Among his literary labors was a translation of his friend Lavater's "Aphorisms on Man." He wrote in a clear and vigorous style, and his lectures before the royal academy were considered among the best specimens of art criticism in English literature. As a painter Fuseli

possessed great invention, and his mind was capable of the most daring conceptions; but his imagination was too active for the control of his judgment, and the unnatural contortions and superfluous energy of his figures show that he had neither a true idea of form nor a just appreciation of the genius of Michel Angelo, of whom he affected to be an imitator.

FUSIBILITY, Fusion. Bodies are said to be in fusion when, by absorption of latent heat, they pass from a solid to a liquid state. The property of fusibility at some temperature is probably possessed by all bodies, but some are so altered by chemical changes among their own elements or by the action of external bodies in contact, that they cease to retain their individual characteristics before their melting point is reached. Although it seems that in some crystalline organic compounds, and also in some of the fats, the fusing point varies after the body has been once melted, it is generally the case that the fusion takes place at a constant temperature for the same body, that this point is ascertained for many, and is given with each as one of the distinctive qualities. Carbon, however, resists this determination, and the assertions of its fusibility made by some experimenters are not generally admitted as establishing the fact. The range of the fusing point of bodies is very great, some existing in the solid state only far below the ordinary temperatures, while others require the most intense artificial heat to cause them to assume the liquid form. This is exhibited in the following table, which comprises many of the bodies thus arranged by Pouillet:

Substances.	Degrees Centigrade.	Degrees Fahrenheit.
English hammered iron.....	1,600	2,912
Steel.....	1,800 to 1,400	2,372 to 2,552
Gray cast iron, second fusion.....	1,200	2,192
White cast iron, very fusible.....	1,050	1,922
Very fine gold.....	1,250	2,282
Standard gold.....	1,180	2,156
Silver, very pure.....	1,000	1,832
Bronze.....	900	1,652
Antimony.....	482	910
Zinc.....	360	680
Lead.....	320	608
Blismuth.....	292	558
Tin.....	230	446
Sulphur.....	114	237
Iodine.....	107	225
Phosphorus.....	43	109
White wax.....	63	154
Spermaceti.....	49	120
Ice.....	00	32
Oil of turpentine.....	-10	14
Mercury.....	-39	-88

The fusing point of oils, &c., is ascertained by introducing them together with a fine thermometer into small glass tubes, and placing these in water, which is gradually heated till the substances melt. The thermometer indicates the temperature. The method of determining the high melting points of the metals, &c., will be described in the article PYROMETER.

FUSIBLE METALS. See ALLOY, and BISMUTH.

FUSTIAN, coarse twilled cotton fabrics, including corduroy, velveteen, velverett, thick-sett, moleskin, &c. The common fustian is a

twill of 4 or 5 leaves, of close and stout texture. Velveteen differs from velvet only in the material, which is cotton, while that of velvet is silk. Some fustians also are made in the same manner as satin. Moleskins are smooth fustians shorn before dyeing; beaverteens are the same material, but shorn after dyeing. Canton is a fustian with a fine cord visible upon the one side, and a satiny surface of yarns running at right angles to the cords upon the other side. The colors of these goods are usually leaden, olive, or dark.

FUSTIC, the dye wood of the *morus tinctoria*, a tree which grows to a great height in Brazil and the West India islands. A yellow dye is obtained by boiling the wood, and this is principally used for converting silks and woollens, cotton yarns and light fabrics, already dyed blue, to a green. Its use is almost wholly for compound colors—bichromate of potassa and lead giving a better yellow. The yellow crystalline substance morin separates from a concentrated decoction of fustic by cooling. The wood is known as old fustic to distinguish it from the wood of the *rhys cotinus*, or Venice sumach, which is sometimes called young fustic, but more properly *fuset*, the name used by the French. It is a shrub cultivated in Italy and the south of France for purposes of dyeing and tanning. Its wood gives a yellowish decoction, which is used as an assistant to procure some particular tint. The color is too fugitive for use alone. The principle fustin is extracted from this wood.

FUTTEHGHUR, FUTTEGHUR, or FATAGHUR, a military station in the district of Furruckabad, N. W. provinces, British India, on the right bank of the Ganges, 8 m. below Furruckabad, of which it is little more than the cantonment, and 703 m. N. W. from Calcutta. It contains a church, and a large factory and storehouse of gun carriages. On June 18, 1857, the Futtehghur troops suddenly rose, and the Europeans, numbering about 100, of whom 80 were fit to bear arms, fortified themselves in the yard of the gun carriage warehouse, where they made a gallant defence until July 4. Then, driven to extremities, they embarked on the river, where many perished by drowning or were shot by the rebels. A few reached the shore and escaped; one boat kept on its voyage to Bittoor, where its occupants were seized, placed in confinement at Cawnpore, and made to share the fate of the unhappy European residents of that town.

FUTTEHPOOR, a district of British India, in the Doab, having N. E. and E. the Ganges and the province of Allahabad, and S. W. and N. W. the Jumna and Cawnpore; area, 1,583 sq. m.; pop. 679,787. The climate, like that of southern Oude, is remarkable for its aridity and wide range of temperature. The soil is fertile, and the principal productions are indigo, wheat, barley, cotton, opium, and sugar cane. The great trunk road from Calcutta to Delhi and the northern Doab passes through the ter-

ritory of Futtehpoor. This district formerly belonged to the nabobs of Oude, but was ceded to the E. I. company in 1801, who annexed it to the presidency of Bengal. Since the division of that presidency it has constituted part of the government of the N. W. provinces.—FUTTEHPoor, the capital of the above district, is a large, well built town, 70 m. N. W. from Allahabad, with which it has communication by the great trunk railway, opened to this point March 25, 1858; pop. 20,864. The town was taken by the rebels during the great revolt, and was recaptured by Gen. Havelock, July 12, 1857, after an engagement of 4 hours, in which the rebels suffered severely and lost 12 guns, while no British soldier was either killed or wounded.

FUTTIPOOR SIKRA, or FUTTEHPoor SIKRI, a town of the N. W. provinces, British India, in the district of Agra, and 28 m. W. from the city of that name; pop. 5,949. It is enclosed by a high stone wall, 5 m. in circuit, with towers and battlements, but contains little more than heaps of massive ruins, a grand mosque, and a good bazaar. The mosque is built on a commanding hill, and is still in tolerable repair. Its gateway is 73 feet high from the pavement to the summit of the interior outline, or 120 feet to the exterior summit. Westward of it are the remains of a vast palace, with terraces, gardens, irrigating canals, wells, and long rows of handsome stables. All the apartments are

arched, and appear to have been highly decorated. Near it there is a column 40 or 50 feet high, built of composition moulded to imitate elephants' tusks; and outside the walls is a ruined embankment, 20 m. in circuit, which pent up the waters of a torrent till they formed a broad lake, on the margin of which was an amphitheatre for public games, elephant fights, and other amusements. These great works were constructed as late as the year 1571 by the emperor Akbar. On Oct. 28, 1857, a body of rebels were defeated here by a British force from Agra.

FYZABAD, or BANGLA, a town of British India, in the territory of Oude, situated on the right bank of the Goggra, which in the rainy season is here sometimes 1½ m. wide, 89 m. E. from Lucknow; pop. estimated at 100,000. It was founded by Saadat Ali Khan, 1st vizier of Oude, and was beautified by his successors, particularly by Surajah Dowlah, under whom it became the capital instead of the ancient city of Oude or Ayodha, adjoining it on the S. E. In 1775 the seat of government was removed to Lucknow. Since that time the deserted city has been falling to decay, and its population is rapidly decreasing. On June 8, 1857, 2 native infantry regiments, a troop of cavalry, and a detachment of artillery, mutinied here, placed their officers in confinement, and next day sent them in boats toward Dinapoor.

G

G, the 7th letter of the Latin and of almost all other European alphabets, was originally the 3d in the Phœnician and other ancient Semitic graphic systems, as well as in the Greek and ancient Italic. Its Semitic name, *gamal*, *gimel*, changed into *gamma*, arose from its similarity in shape to a camel's neck. It was pronounced in all those languages, and in the Celtic, Mæso-Gothic, Anglo-Saxon, Frisian, and other ancient German tongues, as in our words *go*, *get*, *give*, *glib*. This sound was wanting to the Etruscans and Sabines; and as the Romans first wrote it with Q, like the Umbri, employing K for the corresponding close sound (*e. g.* LECIONES, ECFOCIONT, &c., for *legiones*, *effugiant*, on the *columna rostrata* of Duilius; *Caius*, *Cnæus*, pronounced *Gaius*, *Gnæus*; *Kæso* for *Cæso*, &c.), a freedman of Spurius Carvilius Ruga (6th century of the city) formed the G from the Q, for the designation of this mild guttural sound. As such it was inserted between F and H, in the place of the Semitic *gim*, answering to *gym*. In Armenian and Georgian it is also the 3d letter, in Slavonic the 4th, in the various Irish writings the 10th or 12th, in the Runes *stungen kaun* (pointed K) or *gmael*. *Gim*, the 5th Arabic letter, although made from the 3d Oufic, is uttered with the hissing dental sound of our J; while *ghain*, the 15th (intensive *ain*), represents the deepest

guttural sound with a whirring of *r*. All these circumstances betray the organic affinity of sounds in various idioms. As, moreover, the sounds of *ain* and *ghain* are the prototypes of all vocality (fancality), we obtain *u*, *i* (*y*), with their consonants *v*, *w*, *j* (*y*), which are to be added to *k*, *h*, *f*, *z*. Jacob Grimm's scheme completes these affinities:

Greek.	Gothic.	Old High German.
Γ	K	OH
X,	G	K
K	H (G)	G

The genuine sound of G is guttural, and is thus produced: the posterior part of the tongue is raised toward the *velum palatinum*, which sinks to meet it; after a slight contact both are suddenly withdrawn, allowing the breath to pass, while the larynx oscillates and the margins of the glottis are contracted. This oscillation renders the G more sonorous and mild than K. The spurious sounds are more or less harsh dental hisses. G is guttural in the Romanic languages and in high German before *a*, *o*, *u*; before *e*, *i*, *y*, it is dental and hissing, and might be indicated by *dzh* in Italian, English, and Portuguese, and by *sh* in French (like *s* in *glacier*). In Spanish it sounds in those positions like *h* in *helmet*. The Bohemians pronounce it, even before *a*, *o*, *u*, like *y* in *yard*. In Italian *gli* answer to Fr. *ill mouille*, Span. *ll*, Portug. *lh*,

Magyar *ly*; Ital. and Fr. *gn* to Span. *ñ*, Portug. *nh*, Magyar *ny*. But Magyar *gy* is pronounced as if it were written *dy*. In Latin the final sound of a preposition, followed in composition by a *g*, is assimilated to the latter, as *aggero*, *suggero*, for *ad-gero*, *sub-gero*.—The following are specimens of interchanges of *G* with various letters: *O*, *K*—Heb. *gades*, Arab. *kadis*, heap of sheaves; Heb. *gānas* and *kānas*, to collect, &c.; Gr. *γροπερος* (dark), Lat. *creperus*, *crepuscus*; Προκη, *Progne*; κυκνος, *cygnus*; *rego*, *recti* (recti), *rectum*; *vicesimus* and *vigesimus*; *largo*, *longus*, Provençal *laro*, *long*; *Gades*, *Cádiz*; *crassus*, *grossus*, *acutus*, Fr. *gras*, *gros*, *aigu*; Fr. *cicogna*, second, pronounced *cigogna*, *second*; Gr. *γόνυ*, Lat. *genu*, Eng. *knee*; Lat. *genitus*, Germ. *Kind*; Lat. *generosus*, *generatus*, Eng. *kind*, *kindred*, &c. *Ch*, *H*—Gr. *χην*, Germ. *Gans*, Eng. *goose*, *gander*, Bohem. *hus*; Gr. *χῆνος*, Lat. *hesternus*, Germ. *estern*, Eng. *yester-day*, &c. *I*, *J*, *Y*, *U*, *V*, *W*, *X*—Provençal *esay*, Fr. *essai*, *essay* (barb. Lat. *ezagium*); Lat. *rex*, *regem*, *regalis*, *lex*, *legalis*, &c., Sanscrit *rajah* (dialect. *rayah*), Fr. *roi*, *royal*, Sp. *rey*; Fr. *loi*, Sp. *ley*, Eng. *law*; Germ. *Nagel*, *Segel*, *Regen*, *Tag*, *Säge*, *sagen*, *folgen*, *sorgen*, &c., Eng. *nail*, *sail*, *rain*, *day* and *dawn*, *saw*, *say* and *said*, *follow*, *sorrow*; Lat. *gilvus* (*helvus*, *fulvus*, *flavus*), Germ. *gelb*, Eng. *yellow*; Lat. *hortus*, Germ. *Garten*, Eng. *yard*, *ward*; Germ. *Hagen* and *Hain*, *Hecke*, *Hagedorn*, Fr. *Haie*, Eng. *Hague*, *hedge*, *hawthorn*; Gr. *γυρεν*, Lat. *gyrare*, Provenç. *virar*, Fr. *vire*, whence *environ*, &c. Promiscuous examples: Germ. *Gundobert*, Fr. *Jombert*; Ang. Sax. *gaflād*, Eng. *gavelock*, Fr. *javelot*; Sp. *hielo*, *hiema*, *hieso* (obsolete *yelo*, *yema*, *yeso*), from Lat. *gelu*, *gemma*, *gypsum*; Sp. *hermano*, (Portug. *irmão*), *hinojo*, from Lat. *germanus*, *genu* (*geniculum*); Sp. *laja*, from Germ. *Lage*; Germ. *schlagen*, *Schlacht*, Eng. *slay*, *slaughter*. Compare *guardian*, *guerre*, *guêpe*, *gain*, *Gallia*, with *warden*, *war*, *vespa*, *win*, *Wallon* and *Wales*; Fr. *Jacoux*, Lat. *Gabali urbs*; Slavic dialects, *hospodin*, *hlava*, *holub*, *Halica*, *hora*, &c., with *gospodin* (master, lord), *golova* (head), *golub* and *golomb* (Lat. *columba*), *Galicia*, *gora* (mountain), &c.; *gallus* with Germ. *Hahn*. Gr. *καμπη* (a bent) gave Fr. *jamba*, *ingamba*, Eng. *ham*, Fr. *jambon*. Unorganic, accidental substitutions: Fr. *changer*, from barb. Lat. *camdiare*; Turkish *Gharandaberk* (for Prussia), from *Brandenburg*; Gr. *γαλαρος* and *βαλαρος*, Lat. *glans*, Eng. *acorn*; Gr. *γληχων* and *βληχων*, whence Lat. *pulegium*; Gr. *Δημητηρ* and *Γημητηρ*, *δευκος* and *γλευκος*, *γλυκυς*, Lat. *dulcis*; Gr. *σαγμα*, Romanic *salma*, *soma*, Germ. *Saum*, load of a beast of burden; *Bagdad*, Ital. *Baldacco*; Gr. *σμαραγδος*, Ital. *smaraldo*, Fr. *émeraude*. The degeneration of the guttural *G* into the dental is foreshadowed by the Greek *Z*, which sounds as if it were written with the English *ds* or *ed* combined; hence the correspondence between *ζηλος* and Ital. *geloso*, Fr. *jaloux*, Eng. *jealous*; *Ζευς*, *Διος*, *Διеспiter*, *Jupiter*, Ital. *Giove*, like *giorno* from Lat. *diurno*, Fr. *jour*, &c. *G* is omitted in Latin *fibula*, *examen*, *con-*

tamino, &c., from *sigibula*, *exagmen*, *contagmin*; *nascor*, *noseo*, *narus*, *nauus*, which correspond to *γίγνομαι*, *gignor*, *γινωσκω*, retaining the *g* in compounds, as in *cognatus*, *cognitus*, *ignarus*, *ignavus*; Ital. *Aosta*, Fr. *aodt*, Lat. *Augusta*; Ital. *nero*, *leale*, *sciaurato*, *conoscere*, from Lat. *nigro*, *legale*, *exaugurato*, *cognoscere*, &c.; Sp. *pereza*, Fr. *paressa*, Lat. *pigritia*; Provençal *flairar*, Fr. *flairer*, Lat. *fragrare*; Ital. *coitare*, *freddo*, *paese*, &c., Sp. *cuidar*, *frio*, *país*, from Lat. *cogitare*, *frigidus*, *pagenae*; Ital. *augmentare*, *frammento*, from Lat. *augmentare*, *fragmento*; Fr. *bénin*, *malin*, Lat. *benignus*, *malignus*. The German particle *ge* (Lat. *cum*, *que*, *ac*), a formative of the past participle, collective nouns, &c., is expressed in English by *e*, *y*, *a*; thus: *enough*, *yclad*, *agone*, Germ. *genug*, *gekleidet*, *gegangen*. From the last we obtain also *yon*, *yonder*.—During the decline of Latinity *G* was used to designate 400, and 400,000. As an abbreviation it denotes Gellius, Gallia, Germania, Galeria tribus, gens, gratia; and in the middle ages Senarius. On modern coins it indicates Poitiers, Geneva, Nagy-Bánya in Hungary, and Stettin in Pomerania. It is the last dominical letter.—In music, it is the name of the 5th diatonic interval, and the 8th string of the diatonic-chromatic string. It is the clef—altered into *g*—of the violin or the treble. Capital *G* marks the deepest tone of the human voice; its octave being the small *g*. It is named *sol* in solmization.

GABELENTZ, HANS KONON VON DER, a German philologist, born in Altenburg, Oct. 18, 1807, has written *Éléments de la grammaire Mandchoue* (Altenburg, 1832); *Grundzüge der Syrischen Grammatik* (1841); *Beiträge zur Sprachenkunde* (Leipzig, 1852–'8); *Grammatik und Wörterbuch der Kassiasprache* (1857), &c.

GABELLE, a French word derived from the German *Gabe*, gift or tribute, meaning originally every kind of indirect taxes, but afterward applied exclusively to the duty upon salt. This, from the beginning, was the most unpopular of taxes; its arbitrary assessment, and the tyrannical measures of the officers intrusted with its collection, frequently caused rebellions among the poor people in the provinces of France; while every kind of subterfuge was resorted to in order to avoid the payment of it. It was finally repealed in 1790.

GABOON RIVER, called also the Mpongwe in the language of the people at its mouth, is a large river of western Africa, in lat. 0° 30' N., long. 9° E., about 120 miles in length, which takes its rise in the Sierra del Crystal mountains. It empties into a large bay 12 or 15 m. wide, 10 long, and 7 wide at its mouth, which receives also the waters of several smaller streams, and in which are two islands known as Parrot and König islands. The Gaboon is a broad and deep stream, with hardly any current, the mass of its waters being due to the tide, which rises from 7 to 9 feet at 60 m. from its mouth. The river is very unhealthy; mangroves abound along its shores. At the mouth of the river the French established in 1843 a fortified factory.

The exports in 1854, consisting chiefly of various kinds of gum, amounted in value to \$174,689.

GABRIEL (Heb., the mighty one of God), the angel sent to Daniel to interpret the vision of the ram and the he-goat (Dan. viii.), and to communicate the prophecy of the 70 weeks (Dan. ix. 21-27); employed also to announce to Zachariah the birth of John the Baptist (Luke i. 11), and that of the Messiah to the Virgin Mary (Luke i. 26). Though nothing is stated in the Scriptures concerning his rank, he is accounted both by Jewish and Christian writers one of the archangels. According to rabbinical legends, he is the prince of fire, and presides over the ripening of fruit; he alone of the angels understood Chaldee and Syriac, and taught Joseph the 70 languages spoken at Babel; and he with Michael set fire to the temple at Jerusalem and destroyed the host of Sennacherib. Mohammedan writers esteem him one of the 4 most highly favored angels; he is styled the spirit of truth, and to him a copy of the Koran was committed, which he dictated in successive portions to Mohammed.

GACHARD, LOUIS PROSPER, principal archivist of Belgium, born in France about 1800, was at first a journeyman printer, joined the Belgian revolution of 1830, was naturalized in Belgium in 1831, appointed archivist, and in 1834 a member of the academy of Brussels. He has most diligently explored the archives of Simancas in Spain, and others at home and abroad, and has published a great number of works and documents relating to the history of Belgium. Among his more recent publications are: *Correspondance de Guillaume le Taciturne* (4 vols. 8vo., Brussels, 1847-'51); *Correspondance de Philippe II. sur les affaires des Pays-Bas* (3 vols. 4to., Brussels, 1848-'51); *Correspondance du duc d'Albe sur l'invasion du comte Louis de Nassau en Fries* (Brussels and Leipsic, 1850); *Lettres écrites par les souverains des Pays-Bas aux états de ces provinces, 1559-1794* (Brussels and Leipsic, 1851); *Retraite et mort de Charles V.* (Brussels, 1854); and *Relations des troubles de Gand sous Charles V., par un anonyme*, accompanied with 330 documents (4to., Brussels, 1856). Mr. Prescott says, in his edition of Robertson's "History of Charles V." (Boston, 1857), that M. Gachard's work on that emperor places at the disposition of the future biographer of Charles the original materials with which to reconstruct the history of his latter days. During the recent discussions in Brussels (July, 1859) respecting a national monument to Egmont and Horn, the city authorities decided against it, chiefly upon the ground of the new and less favorable light thrown upon the character of these heroes by the historical documents which were published under M. Gachard's auspices.

GADARA, a city of Palestine, the capital of Peræa (or "the country beyond the Jordan"), and one of the 10 cities called the Decapolis. It was E. of the Jordan, and about 8 miles S. E. of Lake Tiberias, and gave its name to the can-

ton or district known as Gadaritis or the country of the Gadarenes. In Matthew it is called the country of the Gergesenes, but this term, as well as the existence of the city of Gergesa, is supposed to have been invented by Origen in the endeavor to reconcile various readings, as no such city can be traced. Though now wholly in ruins, in the time of Josephus Gadara was an important city, strongly fortified, having a court of justice, and in its vicinity several famous hot baths and medicinal springs, reckoned by the Romans inferior only to those of Baia. It was probably near this place that Christ wrought the miracle recorded in Luke viii. 26-36, on the demoniac who "had his dwelling among the tombs;" and we are told by modern travellers that there may still be seen the remains of those ancient tombs, hewn in the rocks by the early inhabitants of Galilee, which even now seem a fit resort for such wretched outcasts of society as had their dwelling in them 2,000 years ago.

GADDI, I. GADDO, a Florentine artist, born in 1249, died in 1312. He was an excellent worker in mosaic, and a friend of Cimabue, whose manner he combined with the Greek style then prevalent in Italy. He is considered the founder of the modern mosaic art, which, in conjunction with his friend Andrea Taffi, he brought to great perfection. He also painted altarpieces. II. TADDEO, son of the preceding, a painter, born in 1300, was living in 1352. He was the godson and favorite pupil of Giotto, whose style he developed, and whom he is even considered to have excelled in beauty and grandeur. Many of his finest works in Florence, and all that he painted in the Campo Santo at Pisa, have been destroyed by time, but his smaller pictures are to be found in the principal galleries of Europe. His decorations of the Spanish chapel in the church of Santa Maria Novella at Florence, in competition with Memmi, are among the finest specimens of art produced in the 14th century. Some figures of the fathers of the church in the latter series, representing religion, have been considered the grandest development of the allegorical style introduced by Giotto. On one of the walls of this chapel are the reputed portraits of Petrarch and Laura. Taddeo was also distinguished as an architect. III. ANGELO, son of the preceding, also an artist, born, according to Baldinucci, about 1324, died in 1389. He was an imitator of his father and of Giotto, but did not improve in proportion to his abilities. He lived for many years in Venice, where he engaged in commerce, and has been considered, though on doubtful authority, the founder of the Venetian school.

GADE, NIELS WILHELM, a Danish composer, born in Copenhagen, Oct. 22, 1817. He commenced the study of music at a comparatively advanced age, and in a few years became an accomplished performer on the violin and piano forte, after which he devoted himself to composition. In 1841 his overture entitled *Nach Klänge von Ossian* ("Echoes of Ossian") received

the prize of the Copenhagen musical union, and secured to him a royal stipend to travel and study his art abroad. He passed several years in Germany and in Italy, and greatly increased his reputation by a symphony in C minor. The favor with which this work was received in Leipsic induced him to visit that city, where in 1844 he was appointed to succeed Mendelssohn in the direction of the Gewandhaus concerts. In 1850, having received the appointment of royal chapel master to the king of Denmark, he returned to Copenhagen, where he has since resided. Among his published works are 4 symphonies, a number of overtures, sonatas, quintettes, and romances, *Comala*, a lyrical drama, and the *Nibelungen*, an opera. Some of his symphonies have been performed with effect in England and the United States, and the first, from its romantic, dreamy tone, is a favorite in the concert room.

GADFLY, a dipterous insect, belonging to the genus *tabanus* (Linn.), with 3-jointed antennæ and wide-spreading wings. The gadflies are among the most bloodthirsty and tormenting of insects; they attack not only man, but cattle, horses, camels, and various ruminating animals. The most common species in the United States is the *T. atratus* (Fabr.), of a black color, with a whitish bloom on the back, like that of a plum; the eyes are very large, almost meeting at the top of the head, and of a shining purplish or bronze black color, with a jet black band across the middle; it is about an inch long, with an expanse of wings of nearly 2 inches. The orange-belted gadfly (*T. cinctus*, Fabr.) is smaller and less common, black, with the first 3 abdominal rings orange-colored. A smaller and very common species is the *T. lineola* (Fabr.), which has a whitish line along the top of the hind body. There are many other American species, described and undescribed. There are about 40 European species, for a knowledge of whose habits and metamorphoses we are principally indebted to De Geer. The species which so torments cattle is the *T. bovinus* (Linn.), about an inch long; the thorax and abdomen are dark brown, the former with yellowish hair, and the latter with a reddish yellow cross band on the hinder edge of the segments, and bright yellow triangular spots; abdomen yellowish gray, with black triangular spots; thighs dark brown, and tibiae bright yellow. These insects appear about the end of June, and continue their attacks through summer; the proboscis, though not very long, is armed with 6 very sharp needles, by which they can pierce the thickest hide. It is said that they will not touch a horse whose skin has been thoroughly washed with a strong decoction of walnut leaves. Camels are worried by a species of *tabanus*; and the moose is so tormented by them that he immerses himself in water to escape their attacks, leaving out only the tip of the nose for purposes of respiration.—In the allied genus *chrysops* (Meigen), or golden-eyed gadflies, may be mentioned the *C. cæcu-*

tiens (Meig.), about $\frac{1}{2}$ of an inch long, common in Europe in meadows and pasture lands, stinging both men and horses very severely; the yellowish brown thorax is marked with 8 long black stripes; wings white with blackish brown spots; abdomen yellowish. American species are *C. ferrugatus* (Fabr.), of a black color, and *C. vittatus* (Wied.), striped black and yellow; they are found in woods and thickets in July and August. The genus *hæmatopota* (Meig.) contains the troublesome gadfly called *cleg* in Scotland; this, the *H. pluvialis* (Meig.), is about the size of the common house fly; the large eyes are greenish, with 4 undulating brown bands running through each of them; the body is gray, with brownish cross stripes; the wings gray, spotted with brown. It attacks man, cattle, and especially horses, in sultry weather just before rain; the wounds are painful at the time, but are not followed by any lasting burning or itching.—The name of gadfly is also given to several species of *æstrus*, especially to that one which deposits its eggs about the knees and sides of the horse, and which, conveyed into this animal's stomach, constitute the disease known as bots. (See BOTS.)

GADSDEN, a N. co. of Fla., bordering on Georgia, bounded E. by the Ocklockonee river, and W. by the Appalachicola; area, about 1,260 sq. m.; pop. in 1850, 8,783, of whom 4,879 were slaves. It has an uneven surface and a fertile soil, suitable for tobacco, cotton, sugar, &c. The productions in 1850 were 776,177 lbs. of tobacco, 292,850 bushels of Indian corn, 143,000 of sweet potatoes, 65,403 gallons of molasses, 5,609 bales of cotton, and 108,370 lbs. of rice. The production of tobacco and molasses was greater than that of any other county in the state, and that of Indian corn exceeded all but Leon. There were 20 churches and 800 pupils attending public schools. Capital, Quincy.

GADSDEN, CHRISTOPHER, an American statesman of the revolutionary period, born in Charleston, S. C., in 1724, died in the same city, Aug. 28, 1805. He was sent to England to be educated, and studied under the care of his relatives, returning to Charleston in his 17th year. He was soon after apprenticed to a merchant in Philadelphia, with whom he remained till his 21st year. After a second visit to England, he engaged in mercantile business in Charleston. His father had possessed a large estate in Charleston, but had lost it in play with Admiral Anson, on his visit to that city in 1733. The success of Christopher in commerce enabled him to recover by purchase all this property. He was one of the boldest in denouncing British oppression from the time of the stamp act. Near his residence was a wide-spreading oak, under which the patriots were wont to assemble in 1765 and 1766 to discuss the political questions of the day. The oak was therefore called the "liberty tree," and beneath it, amid the rejoicings which followed the repeal of the stamp act in 1766,

Gadsden, who was in correspondence with Samuel Adams, warned his friends not to be lulled into a dangerous inactivity. It is claimed that more than 2 years before he had first spoken of American independence. As the revolution advanced, he was one of the most resolute patriot leaders in both civil and military affairs. He was a delegate to the stamp act congress, which assembled in New York in 1765; a delegate to the first continental congress in 1774, in which he urged an immediate attack upon Gen. Gage at Boston; became senior colonel (and afterward brigadier) of 3 South Carolina regiments in 1775; was actively engaged at the siege of Charleston in 1776; was one of the framers of the constitution of South Carolina, adopted in 1778; resigned his military commission in 1779; and, as lieutenant-governor of the state, signed the capitulation when Charleston was taken by Sir Henry Clinton in 1780. Shortly after, in open violation of the terms of capitulation, he was suddenly arrested with 77 other influential public men, hurried on board a prison ship, and conveyed to St. Augustine. He alone of the prisoners refused to enter into any engagements whatever to secure a degree of freedom on parole, and was therefore incarcerated for 42 weeks in the dungeon of the castle of St. Augustine. Being exchanged, he was sent to Philadelphia, and after his return to Charleston, as member of the state legislature, notwithstanding the violence he had suffered, he opposed the confiscation of the property of loyalists. He was elected governor of the state in 1782, but declined the honor, preferring to retire to private life.

GADSDEN, CHRISTOPHER EDWARDS, D.D., grandson of the preceding, third bishop of the Protestant Episcopal church in South Carolina, born in Charleston, S. C., Nov. 25, 1785, died in the same city, June 24, 1852. He was graduated in 1804 at Yale college, where he began a life-long friendship with J. C. Calhoun, was ordained deacon in 1807, and after having charge for 2 years of the parish of St. John's, Berkley, was in 1810 admitted to the priestly office, and elected assistant minister of St. Philip's church, Charleston, with which he was connected during the remainder of his life. It is the oldest church in the diocese, and he became its rector on the death of the Rev. J. D. Simons, in 1814. He was influential in 1810 in establishing the Protestant Episcopal society for the advancement of Christianity in South Carolina, of which he was from the first a trustee, and from 1840 *ex officio* president. On the death of Bishop Bowen, in 1839, there were two parties in the diocese, each of which had its candidate for his successor. Dr. Gadsden was elected on the first ballot by a small majority of the clergy and a large one of the laity. After the adjournment of the convention, he called the clergy around the chancel, and proposed the nomination of some third man upon whom they could all unite, and in whose favor he would most gladly decline the office. The tone

and import of the address had a most conciliatory effect, and resulted in a general acquiescence in his election. He was consecrated bishop at Trinity church, Boston, June 21, 1840, and on Sept. 9 following held his first confirmation in St. Michael's church, Charleston, when 126 persons, more than 20 of whom were colored, became subjects of that rite. On his visitations he was particularly attentive to the colored people, often collecting them for purposes of devotion and instruction, and thus setting an example which was followed with happy effects by his presbyters and deacons. He published several sermons and charges to his clergy, an "Essay on the Life of Bishop Dehon" (1838), and many contributions in the "Gospel Messenger," of which he was editor.

GADSDEN, JAMES, an American statesman, brother of the preceding, born in Charleston, S. C., May 15, 1788, died there, Dec. 26, 1858. He was graduated at Yale college, and was engaged in commerce till upon the declaration of the war of 1812 he solicited a commission in the army. Appointed a lieutenant in the engineer corps, he was variously engaged in Canada and New York, and after the peace was selected as aide-de-camp of Gen. Jackson in the expedition to examine and report upon the military defences of the gulf of Mexico and the S. W. frontier. In the following year he was appointed to review the examinations in coöperation with Gen. Bernard, and published in a separate report conclusions different from those of his associate. In 1818 he accompanied Gen. Jackson in the Seminole campaign, and took part in the capture of St. Mark's, where Arbuthnot was made prisoner; and when Ambrister, the confederate of Arbuthnot, was subsequently arrested at Suwannee, Gadsden at the head of a detachment captured a schooner in the service of the enemy, on board of which was found the correspondence that led to the condemnation and execution of these two leaders of the Indians. At Pensacola he planned the approaches and established the batteries which forced the governor, Massot, to surrender at discretion. At the close of the Indian war he was made a captain, and detailed to take charge of the works to be constructed for the defence of the frontier on the gulf. He was engaged in the fortification of Mobile bay, when he was called to the military staff of Gen. Jackson, as inspector-general of the southern division, with the rank of colonel. He accompanied Jackson to Pensacola when the latter took possession of Florida as governor, and was active in reconciling a dispute between him and the Spanish governor concerning the interpretation of the treaty between the two countries. Upon the reduction of the army in 1822, Col. Gadsden was retained, and for several months was employed as adjutant-general with Mr. Calhoun, who was reorganizing the war department, but for political reasons his name was rejected by the senate. He then became a planter in the wilds of Florida, where

under a commission from President Monroe he effected a treaty for the removal of the Seminoles from middle to southern Florida, and was the first white man who crossed Florida through jungles and morasses from the Atlantic to the gulf. He resumed agricultural pursuits near Tallahassee, but soon became president of the South Carolina railroad, was occupied for several years with commercial enterprises, and afterward engaged in the new culture of rice by tidal irrigation near Charleston. He was recalled to public life by President Pierce, who conferred on him the mission to Mexico, an office which the issues that had grown out of the execution of the treaty of Guadalupe-Hidalgo made one of great difficulty. Disputes had arisen concerning the boundary line between Chihuahua and New Mexico, involving the possession of the Mesilla valley, of which, though claimed by the United States, the Mexicans took armed possession. The 11th article of the treaty, imposing upon the United States the obligation to restrain the Indian marauders on the Mexican frontier, had been neglected, and the reclamations in consequence amounted to between \$15,000,000 and \$30,000,000. Gen. Gadsden concluded a convention, Dec. 30, 1853, by which a new boundary was agreed upon, and by which were secured all the objects which had been erroneously supposed to be attained by the original treaty, the 11th article being abrogated, and a commission provided for the adjustment of claims. For the territory now called Arizona, the United States was to allow Mexico \$10,000,000. Gen. Gadsden was the bearer of his own despatches to the government, and the treaty was finally confirmed by the senate, but with such modifications as made it necessary for the envoy to return to Mexico and renew the negotiation. He had reconciled Santa Anna to the modifications when a revolution drove the dictator from the country, and Gen. Gadsden engaged in negotiations with the new administration when he was superseded, and retired to private life and the pursuits of agriculture, which occupied him till his death.

GADWALL, a fresh water or river duck of the sub-family *anatina*, and the genus *chaulasmus* (Gray). In this genus the bill is as long as the head, the lamellæ distinctly visible below its lower edge, and its color black; the head and neck brownish white, each feather spotted with dusky, and the top of the head generally with a reddish tinge; lower neck, breast, back, and sides banded with narrow bars of black and white; rump and tail coverts black; greater wing coverts velvet black, middle chestnut, and speculum white with a black border. From its general color it is often called the gray duck. The length is about 22 inches, the extent of wings 85, and the weight about 1½ lbs. The only species described is the *C. streperus* (Gray), which is generally considered the same in America and Europe; our species presents some slight differences in measurements and coloration, and it may be that a careful exami-

nation would prove the two birds different species, as the general rule, except in a few arctic species, would lead us to believe. It occurs from the fur countries to Texas, in both of which localities it breeds; it is most common in the interior, especially on the larger rivers; it arrives with the widgeon in the vicinity of New Orleans in the autumn, in small flocks, passing the winter in the large lakes near the gulf of Mexico, feeding on small fish, insects, and aquatic grasses; the flesh is considered excellent eating. The gadwall is a good diver and swimmer, and walks uncommonly well; it is a rapid flier, with a whistling noise of the wings; in its excursions on land it nibbles the tender grass, and will eat acorns, seeds, and grain. Experiment has proved that this species is capable of domestication, the peculiarity of the plumage being retained in this condition.

GAEL, or **GAIL** (Gaelic, *Gadhel* or *Gaoidheal*), the plural of *Gal* or *Cal* (akin to Latin *celo*, to hide, as the people dwelt or were hidden in forests; or more probably signifying wanderer), the name of the northern and western branch of the great Celtic family of nations, whose other branch is formed by the Kymri or Oymri. The Gael inhabit the Scotch highlands and Ireland, and distinguish themselves as Gael Albinach, or Gael of Albion, and Gael Erinach, Gael of Erin (from *ar* or *iar*, west, and *is*, island; Romanized into *Iuerna* and *Hibernia*). Both these divisions are called Erse, the former by the Scotch lowlanders, who derive them from Ireland. The descendants of the Kymri dwelling in Wales are called Gwyddel by the Gael, while those in France are named Breiziz (Britons; see **BRETON LANGUAGE**), and those of Cornwall (*corn*, *cairn*, rock, and *gal*) ceased in the 18th century to speak their peculiar dialect. Gadhelic or Gaoidhilg is the epithet especially appropriated to the Irish and to their tongue, and Gaelic especially denotes both the highland Scotch and their language. (See **ERSE**.) Caledonia is composed of *Cal* and *dun* or *don*, mountain; Gaeldoch of *Gael* and *dock*, land; both being names of Scotland; but Gaoldoch or strangers' land is the distinctive name of that part of Scotland which is inhabited by non-Celtic people.—It was believed at one time, even by Gibbon, that the Irish were of Punic origin; but Dr. Prichard and others have proved that they, as well as all other Celts, are of the Indo-European family, as having arrived before the Teutons from the regions on the Oxus and from Media, and having penetrated through the Allophyllic races (see **FINNS**) along the southern shores of the Baltic sea into the west of Europe at a time of which we have no historic data. Traces of this migration, although altered, are found everywhere in the word *Wal* (Gal), as in Wales, Wallon, Wallia (Valais) in Switzerland, Wälsch-land (the German name of Italy), Wallachia (the country of the Ruman), in walnut (this tree having been imported from Italy, the northern part of which was Gallia Cisalpina), &c. A. B. Marx has written an interesting treatise on Gaelic

music (in Erach and Gruber's *Encyclopædia*, 1850), showing the influence of the Celts in the countries above mentioned, and in Spain, Galatia in Asia, and even in Africa, as the music of the Moors was found by Lemprier (1789) to resemble the Celtic modes. See also Skene, the "Highlands of Scotland" (London, 1887); Diefenbach, *Celtica* (Stuttgart, 1889-'92); Wilson, the "Archæologic or Præhistoric Annals of Scotland" (Edinburgh, 1851).

GAËTA (anc. *Caieta*), a fortified city of the kingdom of Naples, in the province of Terra di Lavoro, on the gulf of Gaëta, an arm of the Mediterranean, 76 m. S. E. of Rome; pop. of the city proper, about 3,000, but including its suburbs, 14,800. It is neatly though irregularly built. The principal public edifices are the citadel, one of the strongest fortresses in Italy, and the key of the kingdom of Naples; the cathedral, which is a handsome symmetrical structure, with a fine tower; and the royal palace, which is a favorite summer residence of the Neapolitan kings. Gaëta gives title to an archbishop; and thither Pope Pius IX. fled when the republican party obtained supremacy in Rome in 1848.

GÆTULIA, an ancient country of Africa, situated S. of Mauritania and Numidia, bounded E. by hills separating it from the country of the Garamantes, W. by the Atlantic ocean, and S. according to Pliny, by the river Niger. Nearly all of this region was included in the Sahara or great desert, the W. oases of which, and perhaps some portions of the fertile belt on its N. margin and of the basin of the Niger, were inhabited by the Gætuli. They were one of the two great aboriginal races of N. W. Africa, the other being the Libyans, and had formerly dwelt on the coast of the Mediterranean, but were expelled by the Mauritaniens and Numidians, and driven S. of Mt. Atlas. They were a nomadic race, of warlike disposition and savage manners, living on milk and flesh, clothed with skins, and without regular government. They are by some supposed to have been the ancestors of the Berbers, and of Asiatic origin. They were divided into several tribes, one of which, the Melanogætuli, were nearly black from intermingling with the Nigræ on the S. In the Jugurthine war they served as cavalry against the Romans, but afterward a body of them joined the army of Marius; and from this period to the close of the civil wars we frequently find them serving as auxiliaries with the legions. They were sometimes however troublesome to the Romans, and in the reign of Augustus an army under the command of Cornelius Cossus Lentulus had to be sent against them. The barbarians were vanquished, and the general obtained a triumph and the surname of Gætulicus.

GAGE, THOMAS, the last royal governor of Massachusetts, born in England, died there in April, 1787. He was an active officer during the 7 years' war, was appointed governor of Montreal in 1760, and succeeded Gen. Amherst in 1788 in the chief command of the British

forces in America. Being appointed to supersede Hutchinson as governor of Massachusetts, he arrived in Boston, May 17, 1774, while the people of that colony were preparing to resist the port act framed for their chastisement. But he was qualified neither to reconcile nor subdue, and, though personally esteemed, inspired the public with neither confidence nor fear. He was instructed to seize and punish Samuel Adams, Hancock, and Warren, but durst not even attempt their arrest. As precautionary measures he seized the powder in the public magazine in Charlestown (Sept. 1), and began to fortify Boston, out of which city his power was at an end. He planned the expedition to Concord which resulted in the first battle of the revolution (April 19, 1775), and on June 12 established martial law throughout Massachusetts, and proscribed Samuel Adams and John Hancock by name, offering pardon to all other rebels who would return to their allegiance. After the battle of Bunker Hill (June 17, 1775) Gage was superseded by Gen. Howe, and sailed for England on the following Oct. 10.

GAGERN, HEINRICH WILHELM AUGUST, baron von, a German statesman, born in Baireuth, Aug. 20, 1799. He entered the army of the duke of Nassau in 1815, and fought at the battle of Waterloo as sub-lieutenant. He afterward studied law, and entered the public service of the grand duchy of Hesse-Darmstadt. As a writer and a member of the legislature he opposed the views of the government, and was obliged to resign his office in 1833, after which he devoted himself exclusively to the diffusion of political liberalism. Being considered the leader of the opposition, he was called upon to form a ministry when the popular outbreak of 1848 compelled the government to adopt a liberal policy. He was elected a member of the national German parliament at Frankfort-on-the-Main, and acted as its president until Dec. 15, when he entered the cabinet of the vicar of the empire (*Reichsverweser*), the Austrian archduke John, as prime minister. In that position he avowedly endeavored to reconstruct Germany upon the basis of an exclusion of Austria. His administration lasted only 3 months. He afterward applied all his influence to the promotion of a plan of a limited German union under the leadership of Prussia. He was justly considered the soul of that party which from a convention held at Gotha in 1849 obtained the name of *Gothaer* (men of Gotha), a moderately liberal party, whose political ideal was the British constitution. After having taken part as a volunteer in the Holstein war against Denmark, Gagern went to Heidelberg, and has since lived there in retirement.

GAINES, EDMUND PENDLETON, an American general, born in Culpepper co., Va., March 20, 1777, died in New Orleans, June 6, 1849. He entered the U. S. army as ensign in 1799, was for many years actively employed in frontier duty, and was instrumental in procuring the arrest of Aaron Burr. About 1811 he resigned

his commission, intending to fit himself for the practice of the law; but at the commencement of the war of 1812 he returned to the army, with which he remained connected until his death. At the battle of Chrystler's field, fought Nov. 11, 1813, he rendered important services by covering the retreat of the American forces with his regiment, the 25th, and he subsequently commanded at Fort Erie when the night assault by the British troops under Gen. Drummond was repulsed. For his conduct during the siege of this place, where he was severely wounded, he was promoted to be brevet major-general, having passed during the war by successive promotions through the inferior grades from lieutenant-colonel upward, and received the thanks of congress and a gold medal. He received similar testimonials from the states of Virginia, Tennessee, and New York. He was subsequently engaged in the Creek and Seminole wars, and held the chief command of the southern military district till 1821, when the western division was assigned him. At the commencement of the Mexican war he called out a large force of the southern militia, without awaiting orders, and without obtaining any result commensurate with the expense, for which he was tried by a court martial, but not censured.

GAINSBOROUGH, THOMAS, an English landscape and portrait painter, born in Sudbury, Suffolk, in the early part of 1727, died in London, Aug. 2, 1788. At a very early age he manifested a taste for drawing. Allan Cunningham says: "At 10 years of age, Gainsborough had made some progress in sketching, and at 12 was a confirmed painter." At the age of 15 he was sent to London and placed under the instruction of Gravelot the engraver and Hayman the painter, and soon began to paint landscapes and portraits. But his position did not improve until his marriage in 1746 with a young lady named Burr, of striking beauty, and a fortune which laid the foundation of her husband's independence. He then resided successively in Ipswich and Bath, and in 1774 returned to London, where some portraits which he painted of members of the royal family at once gave him a name and ample employment. He passed the remainder of his life in London, where Sir Joshua Reynolds, his great rival and friend, had settled before him. In 1768 he was chosen one of the original 86 academicians, and from that time until 1784 he sent numerous pictures to the academy, excepting during the 4 years from 1773 to 1777, when, as was supposed, some dispute with Sir Joshua Reynolds deprived the academy of his contributions. It is said that Chatterton sat to him during this interval, and that the portrait was a masterpiece. As a landscape painter Gainsborough achieved the highest excellence, and was the first of his class in England to show any real originality. The "Life of Thomas Gainsborough," by George William Fulcher, edited by his son, appeared in London in 1856.

GAIUS, or CAIUS, a Roman jurist, who flour-

ished during the reigns of the emperors Hadrian, Antoninus Pius, and Marcus Aurelius. Of his personal history little or nothing is known, and even the spelling of his name has been a subject of controversy. From references in the Digest it would appear that he was the author of upward of 15 works, of which the Institutes was by far the most important. This is supposed to have been the first work of the kind not compiled from previous sources, and to have afforded the first instance of a popular manual of Roman law in the sense of modern elementary text books. Such was the estimation in which it was held that after a lapse of 4 centuries from the period of its publication it was incorporated almost bodily into the celebrated Institutes prepared by the order of Justinian. The fame of Gaius as a legal writer, although amply sustained by the latter work, is established on a firm basis by the accidental discovery of a nearly perfect copy of his original treatise, supposed to have been lost after the promulgation of Justinian's compilation. In 1816 Niebuhr in a transient visit to Verona examined a palimpsest in the cathedral library, containing 251 pages, of which one detached and undefaced leaf of 2 pages had been described and partly published by Scipio Maffei 60 years before, with a conjecture that it was part of a compendium of Justinian's Institutes. With this exception the whole original manuscript had been washed and sometimes scratched out and overlaid with the epistles of St. Jerome, and 63 pages had been written over a second time; yet Niebuhr succeeded in restoring and deciphering a portion of it, and at once concluded that it was a treatise of some ancient jurist of celebrity, probably Ulpian. He communicated the results of his labors to Savigny, who published them, together with a learned note suggesting that the ancient text of the parchment was the lost Institutes of Gaius. The sensation caused by these investigations induced the royal academy of Berlin in 1817 to send two accomplished civilians, Göschel and Hollwegg, to Verona, who, after incredible labor in deciphering the characters on the parchment, succeeded in making a transcript of the original writing with the exception of 8 leaves and a few scattered passages which were illegible. A comparison of the work thus recovered with the quotations in the Digest, and its agreement with the Institutes of Justinian, confirmed Savigny's conjecture, and the discovery, by clearing up difficulties in the interpretation of ancient jurisprudence before regarded as hopeless, has been considered to form an era in the study of Roman law. Several editions of the text have been published, that of Göschel of 1842 being considered the best; and commentaries on detached portions by Van Assen, Heffler, Klenze, Böcking, and others, have appeared; but no edition of the whole work with a good commentary has yet been published.

GAJ, LUDVIG, a Slavic journalist, born in Croatia about 1810, studied in Hungary and

Germany, and after having visited St. Petersburg, became one of the chief agitators for a national union of the south-Slavic tribes. He established a national printing office in Agram, introduced a new system of uniform orthography for the Croatian, Slavonian, and Dalmatian dialects, called collectively the Illyrian language, and commenced in 1835 the publication of the "Croatian News." In the following year this paper assumed the title of "Illyrian News," but when the south-Slavic movement, though exceedingly effectual as a counterbalance to the national movement of the Magyars, seemed to become threatening to the interests of Austria, the appellation Illyrian was prohibited, and Gaj styled his journal Croato-Slavono-Dalmatine. In 1848, after the outbreak of the revolution in Austria, Gaj headed a deputation to the emperor, and returned from Vienna with the title of councillor. He continued his agitation against the Magyars, and was elected to the Slavic congress of Prague by the high school of Agram. In consequence of renewed political activity, which appeared untimely to the government, he was arrested for some time in 1853. He is also popular as a poet.

GALACTOMETER (Gr. γαλα, gen. γαλακτος, milk, and μετρος, measure), an instrument for determining the specific gravity of milk, as an indication of its quality. The common hydrometer may be used for this purpose, but a better instrument is that called the centesimal galactometer, invented by M. Dinocourt. This is a glass tube made to float upright in the liquid, and surmounted with a stem upon which are two scales, one intended to be used in skim milk, the other in milk from which the cream has not been removed. The normal range of each quality is designated upon one of the scales, and the divisions above are intended to mark hundredths of water that has been added. Though the specific gravity of genuine milk commonly is found between 1.026 and 1.031, the determination of this is a very uncertain test of its purity. Cream being specifically lighter than milk, its removal leaves the fluid comparatively heavier; water might be added to this, and the specific gravity be thus brought to that of genuine milk. The instrument therefore should be used only in connection with another called the lactometer, the object of which is to determine the proportion of cream present. This being known, and the specific gravity ascertained with the accuracy due to the graduation of the galactometer, the quality of the milk can be more correctly determined than by the use of other instruments.

GALAM, or KAJAAGA, a country of West Africa, in Senegambia, intersected by the parallel of 14° 45' N. and by the meridian of 13° 10' W. It consists of a narrow but densely populated strip along the left (S. W.) bank of the Senegal river, bounded S. by Bondoo and Bambook, and divided by the Faleme into 2 parts, the W., called Lower Galam or Goye, and the E., Upper Galam or Kamera. It is a

mountainous region, abounding in fine scenery, and favored with a fruitful soil and fertilizing streams. The lion, elephant, wild boar, ape, hippopotamus, and crocodile are among its indigenous animals. The inhabitants, who occupy a string of towns on the Senegal, are mostly Serawollis. They are described as a robust, agricultural people, not ignorant of trade, and largely employed as carriers. They exchange the products of the country for European goods, and at one time Galam, or Fort St. Joseph, their capital, was the centre of an active commerce with the French and an important slave depot. Pagan worship is gradually giving way to Mohammedanism; every town has its mosque and priests, and the latter form the wealthiest and most respectable class of the nation. Honesty is a virtue little understood; the boundless exactions of the native chiefs, dignified by the name of customs, have doubtless contributed more to the destruction of commerce than almost any other cause; but in other respects their treatment of whites is friendly. The government is in the hands of a ruler called the *tunka*, whose power, however, is limited by a representative assembly. He derives his authority by collateral succession. The country was visited by Mungo Park in 1795-6.

GALAPAGOS ISLANDS, a group of islands in the N. Pacific ocean, comprising 11 of considerable size and a great number of islets, about 600 m. from the coast of Ecuador, to which state they belong. They lie between lat. 1° 30' S. and 0° 44' N., and between long. 89° 20' and 92° 10' W. The largest of the group, Albe-marle island, is 75 m. long and about 15 m. broad, and its highest summit is, according to Humboldt, 4,686 feet above the level of the sea. These islands are all of volcanic origin, and of comparatively recent formation. Their general appearance is not at all inviting, but in the interior of Charles island is an extensive plain, cultivated by convicts, and producing luxuriant crops of tropical fruits and vegetables. These islands so abound in elephant or land tortoises, which in Spanish are called *galapagos*, that they have derived their name from them. In 1882 the republic of Ecuador converted Charles island into a penal settlement, and sent thither a small colony. When Capt. Fitzroy visited it in 1835, there were 80 houses and some 200 souls, chiefly convicts, on the island. Humboldt in his "Cosmos" says: "Scarcely anywhere else, on a small space of barely 120 or 140 geographical miles in diameter, has such a countless number of conical mountains and extinct craters (the traces of former communication between the interior of the earth and the atmosphere) remained visible. Darwin calculates the number of the craters at nearly 2,000. When that able observer visited the Galapagos in the expedition of the Beagle under Capt. Fitzroy, two of the craters were simultaneously in a state of igneous eruption. On all the islands, streams of a very fluid lava may be

seen, which have forked off into different channels and have often run into the sea. . . . On the largest and most westerly island of the Galapagos group, Albemarle, the cone mountains are ranged in a line and consequently on fissures. The western bay, in which the peak of Narborough, so violently inflamed in 1825, rises in the form of an island, is described by Leopold von Buch as a crater of upheaval, and compared to Santorino. Many margins of craters on the Galapagos are formed of beds of tufa, which slope off in every direction. A part of what in the old descriptions is called tufa, consists of palagonite beds, exactly similar to those of Iceland and Italy, as Bunsen has ascertained by an exact analysis of the tufas of Chatham island, the most easterly of the whole group."

GALATIA, a province of Asia Minor, lying N. E. of Phrygia, of which it was once a part, and called Gallo-Græcia or Galatia from the Gauls, who, having left the army of Brennus, conquered this region and settled in it. No ancient geographer has laid down with precision the limits of Galatia. Its inhabitants, though intermixed with the Greeks, still retained their native language down to the days of the apostle Paul. Callimachus calls them "a foolish people;" and Hilary, himself a Gaul, as well as Jerome, speaks of them as unteachable. Though marked by that warmth and volatility of character for which the Gauls in all ages have been noted, they were less effeminate and less debased by superstition than the natives of Phrygia, and therefore more ready to receive the gospel when it was made known to them. Paul first preached Christianity and organized churches in Galatia. He was there once with Silas and Timothy (Acts xvi. 6) about A. D. 53, and again, several years later, on his return from Corinth (Acts xviii. 23).

GALATIANS, EPISTLE TO THE, addressed by St. Paul to "the churches of Galatia," and forming one of the canonical books of the New Testament. There is little evidence and much diversity of opinion as to when and where it was written. In the Galatian churches were many Hebrew converts, who had incorporated Jewish rites with the ordinances of Christian worship. Some of them seem even to have questioned the divine commission of Paul, with a view of exalting the authority of Peter, who was believed to be at variance with him concerning the relation of the Jewish to the Christian ceremonial. To recall the Galatians to the simplicity of the gospel was the object of Paul in this epistle, in which he vindicates his apostolic commission (i., ii.), urges the doctrine of salvation as the cardinal truth of Christianity, illustrates the relation of the Christian to the Jewish church (iii., iv.), and concludes with exhortations and benedictions.

GALATZ, or **GALACZ** (anc. *Asiopolis*), a town and the only port of Moldavia, capital of the district of Kovourloni, on the Danube, just below the mouth of the Sereth; pop. about 86,000. It is an important commercial town, one of the two

ports on the Danube open to foreigners, and an entrepot for most of the traffic between Germany and Constantinople. Steam packets ascend the river to Vienna, and a line of vessels established by the Austrian Lloyd company connects Galatz with Trebizond and Constantinople. In 1847 steamboat communication was also opened with Odessa. Galatz is a free port, is accessible by vessels of 800 tons burden, and though distant about 80 miles from the sea promises to become the chief emporium on the Danube. Since the removal of many oppressive commercial regulations in 1829 it has made great advances. It exports wheat, maize, barley, tallow, hides, skins, bristles, bones, jerked beef, lard, butter, wool, linseed, yellow berries, barilla, coarse cheese, timber, &c., and imports cotton goods, iron, steel, hardware, sugar, coffee, olives, and olive oil. The value of the exports, chiefly maize, in 1856, was about \$4,000,000, and of the imports \$5,000,000. The trade was formerly monopolized by the Greeks, and is still chiefly in their hands, although the English and other merchants now participate in it more than formerly. Galatz consists of an old and a new portion, the former of which is dirty, ill built, and crowded with miserable wooden huts. The latter has a number of handsome stone buildings, Greek churches, a convent, a hospital, and a large bazaar. A battle was fought here between the Turks and Russians in 1769; the Russians took the town in May, 1789; and the Turks gained a victory here in August of the same year. Between 1848 and 1856 Galatz was on several occasions occupied by Turkish, Russian, and Austrian troops.

GALAXY (Gr. *γαλαξίας κύκλος*, milk circle, the milky way), an irregular band of whitish light surrounding the heavens, stretching in winter evenings from S. E. to N. W., in summer from S. W. to N. E., and caused, as may be seen with telescopes of low power, by numerous stars too faint to be seen singly by the naked eye. It is the almost unanimous opinion of astronomers that this faintness arises chiefly from distance, so that the sun and the fixed stars may be considered as the central portion of an immense flat cluster of stars whose circumference is the milky way. Other specimens of such clusters of stars, it is believed, are visible in some of the great nebulae.

GALBA, **SERVIVS SULPICIUS**, a Roman emperor, born near Terracina, Dec. 24, 3 B. C., died Jan. 15, A. D. 69. Inheriting great wealth and possessing great talents, it was predicted both by Augustus and Tiberius that he would become the head of the Roman world. He attained the prætorship in A. D. 20, and the consulship in 38, carried on a war in Gaul in 39 against the Germans, was intrusted with the administration of Africa in 45, lived in retirement for several years under Nero, but in 61 was invested with the government of Hispania Tarraconensis. He was faithful to the empire till in 68 Vindex rebelled in Gaul, and his own assassination was plotted by Nero. He then

took the title of legate of the Roman senate and people, marched toward Rome, and upon the death of Nero received the imperial dignity from the senate. He offended the prætorian guard by refusing the donative which had been promised in his name, and completed his ruin by adopting Piso, a noble young Roman, for his successor. Otho, who had hoped for the adoption, immediately formed a conspiracy among the soldiers, and Galba was murdered in the forum 7 months after the beginning of his reign.

GALBANUM, a gum resin obtained from India and the Levant. The tree which produces it is not known with certainty. On doubtful authority it has been referred to the *bubon galbanum* of the eastern coast of Africa, to the *ferula ferulago* of Linnæus, and the *F. galbanifera* of Lobel. Lindley named the tree from which he supposed it came *opoidia galbanifera*, and Don from some seeds found in the gum proposed a new genus, *galbanum*, with the specific name *officinale* for the tree producing the gum, or rather the seeds found in it. A German traveller, F. A. Buske, saw the galbanum plant growing on the shores of the Caspian with the gum exuding from it, and according to his description it is a *ferula*, very similar to the *F. erubescens* of Boissier, if not this species. The drug is imported in massive lumps of irregular shapes, apparently made up of agglutinated tears. They are of brownish yellow color, sometimes greenish, the tears sometimes translucent and of a bluish or pearl white color. Its consistency in cold weather is that of wax; in warm weather it is soft and adhesive, and at 212° F. it can be strained, a process requisite to separate the stems and other impurities with which it is commonly mixed. When quite cold it is brittle and may be pulverized. The taste of galbanum is bitterish, hot, and acrid, and its odor balsamic, peculiar, and disagreeable. It is wholly soluble, except impurities, in dilute alcohol; less so in ether. Its specific gravity is 1.312; and its composition, by the analysis of Meissner, is as follows: resin, 65.8; gum, 22.6; bassorin, 1.8; volatile oil, 8.4; bitter matter with malic acid, 0.2; vegetal remains, 2.8; water, 2; loss, 1.4; total, 100. An essential oil is obtained by distillation, of a fine indigo blue color, which it imparts to alcohol. Varieties of galbanum of somewhat different qualities are occasionally met with. The uses of galbanum are medicinal, rarely as an internal remedy, though it possesses stimulant, expectorant, and antispasmodic properties, on account of which it is sometimes prescribed in catarrhs, chronic rheumatism, &c. Its most useful application is in the form of a plaster, alone or in combination with other substances, for promoting resolution or supuration of indolent swellings.

GALEN (GALENTUS), CLAUDIUS, a physician of antiquity, born in Pergamus in Mysia, A. D. 180, died, according to Suidas, in 200 or 201, but according to his Arabic and some other biographers, from 10 to 18 years later. Galen received the rudiments of his education from his father, and

when 15 years of age he began to study logic and philosophy. Two years afterward he was placed under the best instructors in the science of medicine; and at about the age of 20, after the death of his father, he travelled into various countries to complete his studies. He was absent 9 years from Pergamus, and when he returned he was appointed city physician to the school of gladiators. Some popular commotions having arisen in Pergamus a few years after his appointment, he went to Rome, where he remained 4 years and acquired great reputation for skill in anatomy and medicine. As soon as the troubles in Pergamus had passed away, Galen hastened back with the intention of remaining there; but hardly had he reached his destination when he was summoned by the emperors Aurelius and Verus to attend them at Aquileia in Venetia, where a fearful pestilence raged in the camp. The emperors set out for Rome shortly after Galen presented himself. Verus died of apoplexy on the way, and Galen accompanied Aurelius to the capital. When returning to the camp after the apotheosis of his colleague, Aurelius urged Galen to accompany him, but the latter declined under pretence that Æsculapius had enjoined him to remain. How long he sojourned in Rome during his second visit is uncertain, but while there he continually added to his fame by his lectures, writings, and successful practice. We know little more of his latter days than that he ultimately returned to his native city, and died there. Galen was not only the most eminent physician, but also one of the most learned and accomplished men of his age. He was a very voluminous writer on medical and philosophical subjects. There are still extant 88 treatises of his, and 15 of his commentaries on various works of Hippocrates, beside the fragments of his lost works and those writings which are falsely attributed to him. The best edition of his works is that by Kühn, which appeared at Leipzig, 1821-'33, in 20 vols. 8vo. Writings attributed to him were discovered and published in Paris by Minas in 1844, and by Daremberg in 1848.

GALENA, sulphuret of lead, the ore which furnishes most of the lead of commerce. It occurs in highly crystalline masses, which separate into cubical fragments. Its structure is also granular, and sometimes fibrous. Freshly fractured, it presents a brilliant lustre like polished steel, which changes by exposure to a dull lead-gray color. Its hardness is from 2.5 to 2.75; its specific gravity 7.25 to 7.7. Its composition, represented by the symbol PbS, is lead 86.6, sulphur 13.4; but it often contains other metals, as antimony, silver, zinc, iron, and copper, as well as the substance selenium. It is also largely intermixed with the earthy gangues that form the principal portion of the veins in which it is found. From these, and from the sulphurets of zinc and the pyritous copper and iron usually associated with the ore, it is separated as far as practicable before smelting by the processes of stamping or crushing, jigging, &c. (See LEAD,

and METALLURGY.) In some veins and beds it is frequently found in large groups of cubical crystals, which are very free from mixtures with foreign substances. In this form it is met with in the fissures in the limestone of the lead region of Wisconsin, Iowa, and Illinois, imbedded in the clay with which the fissures are filled. Galena is a valuable ore for the silver it often contains, as well as for the lead. In reducing the ore by smelting, the silver all goes with the lead, which is run out; and from this it is afterward separated either by the process of cupellation, or parting by crystallization, or other method. The lead ores do not, however, all contain silver enough to render its extraction profitable; and of those worked in the United States, only the ores of Davidson co., N. C., are sufficiently argentiferous for the separation of the silver to be an object, and yet the separation is so cheaply conducted that 3 oz. of silver to the ton of lead will pay for the operation. Galena much richer in silver than this is a product of numerous veins in the granitic and metamorphic rocks of New England and other parts of the United States; but the more argentiferous it is, the less certain is the yield of the veins in quantity, and none of this character has been found profitable to work. In Cornwall and Devonshire, England, mines of argentiferous galena have been worked profitably for centuries, even when a product of 9 or 10 oz. of silver to the ton of silver-lead was required to pay the expense of separation. The richest metal was from the ores of mines near Beer Alston in Devonshire, which yielded from 80 to 120 oz. of silver to the ton of lead; one portion of the mines, known as the South Hooe, yielded lead containing 140 oz. of silver to the ton. These mines, though now of little importance, were celebrated for their production in the time of Edward I. and II. Other mines produce, some 40, some 50, and some 70 to 100 oz. of silver. In Ireland the product of the lead ores in silver in 1851 was 3,860 oz. of the value of £1,029 6s. 8d. The average yield of the lead was 7 oz. to the ton. The lead from the mine of Shallee yielded 25 oz., of Luganure 8 oz., of Ballyhickey 15 oz., and of Kilbricken 120 oz. Argentiferous galena is a common product of mines upon the continent of Europe, and also of Mexican mines. Among the localities in the United States where it is met with are Shelburne and Eaton, N. H., the lead obtained from the ores of each locality yielding from 3 to 7.53 lbs. of silver to the ton; Middletown, Conn., 40 to 70 oz.; Uxbridge, Mass., a specimen from one of the small veins of which yielded at the rate of 18.53 lbs. troy to the ton; Ancram, Columbia co., N. Y., 25 to 30 oz. to the ton of lead; Ellenville, Ulster co., N. Y., 12 oz.; Phoenixville, Chester co., Penn., 25 to 37 oz. The mines at all these localities have been abandoned.

GALENA, a city of Illinois, county seat of Jo Daviess co., and the centre of the region known as the "Galena lead mines," situated upon both sides of Galena river, 8 m. from its

junction with the Mississippi, 468 m. above St. Louis, and 406 below St. Anthony; lat. 42° 22' N.; pop. in 1882, 1,000; in 1841, 2,225; in 1850, 6,004; in 1859, 14,000. The first house was built at Galena in 1819, the place at that time being known as La Pointe or Frederic's Point. In 1827 a village was laid out by Capt. Martin Thomas of the U. S. army, and named Galena, that being the name of the sulphuret of lead which abounds in the locality. In 1828 the first newspaper was established, entitled the "Miner's Journal," and in the same year the village comprised about 100 houses. The city has a high and healthy location, far enough removed from the Mississippi to be entirely free from the miasmatic exhalations of the river, and yet sufficiently near to enjoy all its commercial advantages. Galena river is always navigable for any steamboats that can ascend the rapids of the Mississippi. The ground upon which the city is built rises abruptly at a short distance from the river on both sides, and some of the bluffs reach a height of upward of 200 feet. These bluffs, which encircle the whole city, are composed of mountain limestone, and give the place an extremely irregular and picturesque appearance. In the environs are many streams of water, which afford ample power for manufacturing purposes. On these streams are 12 or 15 mills. The public and private buildings of Galena are mostly of brick, and many of them in a good style of architecture. There are 12 churches, 2 daily newspapers, 10 public school-houses with 1,500 scholars, a seminary, a U. S. marine hospital, and a custom house and post office built of stone at a cost of \$70,000. There are 3 large steam saw mills, 1 large steam flouring mill, 2 lead furnaces, 2 iron foundries and machine shops, 2 extensive plough manufactories, 5 wagon shops, 2 large furniture manufactories operated by steam, 1 pottery, 8 lumber yards, 3 large leather furnishing houses, 3 soap and candle manufactories, 7 breweries, and 2 carriage manufactories. Two daily lines of steamboats run to St. Paul and St. Anthony, and intermediate points, and 2 daily lines to St. Louis; and there are 4 daily passenger and 2 freight trains of the Illinois central railroad. Galena is 8 hours from Chicago, 18 from St. Louis, 24 from Cincinnati, and 48 from New York. The steamboat tonnage owned there amounts to 4,962 tons, and there were 490 arrivals and departures of steamboats in 1857. The exports of lead in 1857 were valued at \$801,824, while the value of horses, cattle, grain, flour, potatoes, pork, and bacon exported was \$889,014. The total amount of lead shipped from the Galena mines from 1821 to 1858 was 820,622,839 pounds, the value of which was \$82,824,918. The greatest amount in any one year was in 1845, when 54,494,850 pounds were shipped. In 1857 the amount shipped was 34,183,250 pounds.—The Galena mines will be described in the article LEAD.

GALERIUS, CAIUS VALERIUS MAXIMIANUS, a Roman emperor, reigned from A. D. 305 to 311.

A native of Dacia and the son of a peasant, he distinguished himself in the armies by his courage, and was appointed Cæsar in 293 by Diocletian, whose daughter he married. Receiving Thrace and Macedonia for his province, he was defeated by the Persian king Narses, but was so disdainfully received by the emperor at Antioch on his return that he again set out, crossed the Euphrates, and gained a decisive victory over the Persian king. His power was now such that he extorted from Diocletian an edict of proscription against Christianity, which was bloodily executed. After the abdication of Diocletian in 305 he reigned over the East; but when Italy recognized the authority of the usurper Maxentius, he marched thither to besiege Rome, which he had never yet seen, but was defeated by Maxentius, and died at Sardica.

GALES, JOSEPH, an American journalist, born in England about 1760, died in Raleigh, N. C., Aug. 24, 1841. He was originally a printer and bookseller at Sheffield, where he founded and published the "Sheffield Register." His sympathy with the French revolution and his republican principles involved him in difficulty with the government, and in 1798 he sold his journal to James Montgomery the poet, and emigrated to the United States. He settled in Philadelphia, which was then the seat of the federal government, where he conducted the "Independent Gazetteer" for 2 or 3 years. He was the first to introduce the practice of reporting by short hand the debates in congress. In 1799 he sold the "Independent Gazetteer" to Samuel Harrison Smith and removed to Raleigh, N. C., where he established the "Register," which he conducted for nearly 40 years.—JOSEPH, son of the preceding, also an American journalist, born April 10, 1786, in Eckington, near Sheffield, accompanied his father to the United States at the age of 7 years. He was educated at the university of North Carolina, went to Philadelphia to learn the art of printing, and in 1807 settled at Washington as the assistant and afterward as the partner of Samuel Harrison Smith, who in 1800 had removed the "Independent Gazetteer" to Washington and changed its name to the "National Intelligencer." In 1810 Mr. Smith retired from business, and Mr. Gales became sole proprietor of the journal, which was at that time published tri-weekly. In 1813 he took into partnership his brother-in-law, Mr. William W. Seaton, and in Jan. 1813, began to issue the "National Intelligencer" daily. The journal is still conducted and published by Gales and Seaton.

GALESVILLE, the capital of Trempealeau co., Wisconsin, situated on Beaver creek, 6 m. E. of the Mississippi river, 20 m. N. W. of the city of La Crosse, and 12 m. E. of the city of Winona, Minnesota; pop. in 1858, about 500. The village plot was first laid out in the summer of 1854 by the Hon. George Gale, the proprietor of the land on which it is situated. It is the seat of Galesville university, chartered by the legislature of the state in 1854. It has an en-

dowment of \$44,000, of which \$32,000 were given by the Hon. George Gale. A stone edifice for the normal department was erected in 1858 at a cost of \$10,000. It is under the patronage of the Methodist Episcopal church, which nominates one-third of the board of trustees.

GALIANI, FERDINANDO, a Neapolitan author, born in Chieti, Dec. 2, 1728, died in Naples, Oct. 80, 1787. He received a learned education, devoting himself especially to antiquities and political economy. He wrote in his 16th year a remarkable dissertation upon the money current at the siege of Troy, and soon after revenged himself for a slight from the Neapolitan academy by publishing a collection of addresses in prose and verse upon the death of an executioner, after the manner of the academical eulogies. In 1750 he published an ingenious treatise on money, which gained him the friendship of the leading savants and statesmen of Italy and admission into the academy *della Crusca* of Florence. In 1760 he went as secretary of legation to Paris, where he remained 10 years, and became associated with the principal personages of the time in philosophy and letters. He wrote in French in 1770 his *Dialogues sur les blés*, a work which had great success; but as it took part against the economists who were favored by Choiseul, the latter demanded his recall. His brilliant wit and his vast erudition made Voltaire say that Plato and Molière seemed to be united in him. He returned to Naples, received important civil offices, composed a life of Horace with extracts from his poems, and a philosophic comic opera entitled the "Imaginary Socrates." In his various poems and short novels he is often not inferior to Rabelais.

GALIANO, ANTONIO ALOALA, a Spanish author and politician, born in Cadiz, July 22, 1789. He is the son of a distinguished naval officer who fell in the battle of Trafalgar, took an active part in the revolt which resulted in the constitution of 1820, became in 1821 a member of the cortes, and one of the principal and most eloquent orators of the liberal party, but in 1823, after the French intervention under the duke of Angoulême, he was compelled to take refuge in England and resided there 7 years, familiarizing himself with the English language, and writing for the leading English reviews. He was appointed the first professor of the Spanish language and literature of the London university (1828), and published in the "Athenæum" (1834) a "History of Spanish Literature in the 19th Century," which attracted considerable attention. He left England in 1830, but was not permitted to return to Spain till 1834. He has since been again compelled to resort to flight on several occasions, but while in Madrid he was reelected to the cortes, and held other offices, and at the same time exerted much influence as a journalist, chiefly as a writer for the *Piloto*, which he had established in concert with Juan Donoso Cortes. He has translated into Spanish Dr. Dunham's "History of Spain," and Thiers' "History of the Consulate and the Empire."

GALICIA (Ger *Galizien*, Pol. *Galicya*), a crownland or province of Austria, now consisting of the kingdom of Galicia and Lodomeria, the duchy of Auschwitz (Oswiecim) and Zator, and the grand duchy (late republic) of Cracow, lies between lat. $47^{\circ} 50'$ and $50^{\circ} 40' N.$, and long. $18^{\circ} 54'$ and $26^{\circ} 81' E.$, and is bounded N. by Russian Poland, from which it is in part separated by the Vistula, E. by Russia, S. by the Bukowina, or duchy of Czernowitz, and Hungary, being separated from the latter by the Carpathian ridge, and W. by Austrian and Prussian Silesia; area, 80,157 sq. m.; pop. about 5,700,000. Its S. part is occupied by the N. branches of the Carpathians, which in some parts rise to a height of about 6,000 feet, and in some peaks above 8,000; the central region is hilly; the N. belongs to the great Polish plain. From the Carpathians and their offshoots descend all the rivers which cross the country, flowing mostly in a N., and partly in a S. E. direction. Those flowing N., the Biala, Sola, Skawa, Raba, Dunajec, Wisloka, San (which divides the country into two unequal parts), and the Bug, are tributaries of the Vistula; the Pruth and the Dniester flow S. E., the former to the Danube, the latter, with its affluents the Stry, Sered, and Podhorce, to the Black sea. There are some marshes in the N. E. part of the plain, and numerous mountain lakes, called "eyes of the sea," in the Carpathians, some at heights of 3,000 to 4,000 feet; sulphurous and other mineral springs abound in the valleys. The climate is healthy but cold, the country being exposed to the winds from the E. and N., and closed against those from the S.; the winters are long. The soil is varied, only the lower region, where loam and sand prevail, being productive, and in some places fertile; the mountains are rocky and sterile, or wooded. The principal products are wheat, rye, barley, oats, maize, potatoes, peas, beans, and other common vegetables, chicory, clover, flax, hemp, anise seed, rape, tobacco (which is monopolized by the government), hops, pears, apples, cherries, plums, and various other fruits, which are greatly inferior in quality to those of Hungary. There are few vineyards, and these yield no wine, the climate being too rough for the culture of the grape. The pine prevails in the forests, but the oak and beech also grow to an imposing size. Honey and wax, potash and tar, are made in large quantities. The rivers are rich in various kinds of fish. Among the wild animals are the wolf, fox, stag, hare, lynx, and bear, the wild goose, heron, swan, eagle, and vulture. The chief mineral productions are iron, which is found along the whole line of the Carpathians, salt, mostly from the celebrated rock salt mines of Wieliczka and Bochnia in the vicinity of Cracow, and partly from saline springs in the eastern parts of the country, sulphur, produced chiefly at Swosowice, and naphtha; but coal, lead, copper, zinc, silver, and gold are also found. The inhabitants are mostly Slavi, of Polish (including the Mazura, W.

of the San, and Gorale, or western mountaineers) and Ruthenian race; but Jews, Germans, Armenians, and gypsies are also numerous. The nobility are mostly of Polish descent, vivacious, warlike, and ardently attached to their nationality; the peasants are hardy, rude, filthy, intemperate, sluggish, and slavish; the Jews, who are very numerous in the cities, of which they often form half the population, are, with few, sometimes brilliant exceptions, ignorant, bigoted, distinguished by a peculiar half oriental dress and an unpleasant German jargon, and treated with the utmost intolerance. Education, agriculture, and industry are still greatly neglected; wealth is rare; excessive misery, especially among the Jews and mountaineers, a frequent occurrence. Distilleries abound in the villages, and stores and trading shops in the town quarters of the Jews, who before the revolution of 1848 were excluded by the government from both cities proper and villages. The chief manufactures are linen, woollens, paper, wooden utensils, tobacco, leather, potters' ware, and glass. Commerce is limited and carried on mostly by Jews, the chief commercial cities being Cracow, Brody, and Lemberg, the capital. The chief exports are cattle and horses, grain, salt, timber, potash, skins and hides, and wool. Brody is an emporium for the transit trade with Russia. Other considerable towns are Zloczow, Tarnopol, Czortkow, Zolkiew, Brzezany, Stanislawow, Kolomea, Przemyśl, Sambor, Stry, Rzeszow, Sanok, Tarnow, Jaslo, Bochnia, Sandec, and Wadowice—all, as well as Lemberg, capitals of circles of the same names—Jaroslaw, Dukla, Trembowla, and Halicz, from the last of which the country derives its name. The principal existing divisions are those of Cracow, Lemberg, and Stanislawow. The chief courts of justice (*Oberlandesgerichte*), as well as the two universities of the province, and other principal institutions, are at Lemberg and Cracow. The Roman Catholics, about 2,200,000, have bishops at Przemyśl and Tarnow, and an archbishop at Lemberg; the members of the Greek united church, about 2,050,000, mostly Ruthenians, have a bishop at Przemyśl; the non-united Greeks, mostly Moldavians, belong to the bishopric of Czernowitz; the Armenians have an archbishop at Lemberg; the Protestants have a superintendent in the same city; the Jews, about 850,000, have no hierarchical centralization. The literary productions of the country, mostly in Polish, are scanty; a few journals and magazines appear at Cracow and Lemberg; various Hebrew periodicals have lately been commenced. Galicia is the only large division of the empire which has no regular fortresses; transportation of troops, however, is facilitated by good roads, as well as by extensive railway lines, which will soon connect Cracow and Lemberg with each other and with all the principal cities of the empire.—The earliest regular settlement of Galicia was by the Ruthenians (Pol. *Rusini*), who now occupy the eastern division, also called Red Russia. This

was occupied toward the end of the 9th century by the Magyars, then passing to Hungary. Lodomeria, E. of modern Galicia, and then connected with it, was subdued by the Russians at the beginning of the 11th century. Various principalities, the chief of which was Halicz, were formed in the following period under the protection of the kings of Hungary. About the middle of the 13th century Galicia was annexed to Lithuania, in the early part of the 14th to Moscow, and after the death of the last prince of Halicz (1840) to Poland, under the reign of Casimir the Great. From that time it shared the destinies of the latter country, down to the time of its first division in 1772, when it was taken by the empress Maria Theresa, on the ground of the old claims of the crown of Hungary to its possession. It received the title of kingdom of Galicia and Lodomeria, though Lodomeria was in the possession of Russia. The last division of Poland (1795) brought new fragments of Poland into the possession of the Hapsburgs, and the province was divided into E. and W. Galicia. A part was ceded in 1809 to the duchy of Warsaw, and was afterward annexed to Russian Poland; another part was converted by the treaty of Vienna into the republic of Cracow (1815), and was annexed to Austria after the Polish rising of Feb. 1846, which was suppressed in Galicia through a frightful slaughter of the nobility by the peasantry. Insignificant attempts at insurrection were made in the spring of 1848 at Cracow and Lemberg. Several conspiracies have since been detected and severely punished. The Bukowina has been separated from Galicia since the beginning of the reign of Francis Joseph.—For further particulars see the articles on AUSTRIA, CRACOW, and POLAND, to which latter head the history of Galicia chiefly belongs.

GALICIA, a province in the N. W. of Spain, comprising the 4 modern subdivisions of Corunna, Lugo, Orense, and Pontevedra, bounded N. and W. by the Atlantic, S. by Portugal, and E. by the Asturias and Leon; area, about 17,000 sq. m.; pop. in 1857, 1,891,878. It is intersected by numerous narrow valleys, and is mostly mountainous, as the western continuation of the Cantabrian range spreads over the greatest part of the province, and watered by numerous torrents, streams, and rivers. The most remarkable of the latter are the Minho, with its affluents the Sil and the Tea, the Lerez, the Ulla, and the Tambrá, which all become navigable in their lower course and empty into the Atlantic, forming there wide estuaries, or rias, and safe harbors. The coast, being rugged and more broken than those of the Asturias and Biscay, owing to the violent currents of the Atlantic in these latitudes, presents many deep inlets and lofty promontories. Among its excellent harbors are those of Ferrol, said to be the best in Europe, and Vigo, the principal port on the western coast. The climate is cold in the interior and the more elevated regions, temperate in the lower country and

along the coast. The proportion of arable land is very limited. The soil produces flax, maize, barley, wheat, and an abundance of fruits, which constitute the main food of the population; the best oranges and wine are found in the S. part. Fishing and navigation form a principal part of the industry of the people, who also manufacture linen for domestic use. The inhabitants, called Gallegos, are a hardy and robust people, and speak a dialect greatly differing from the common Spanish. About 100,000 of them yearly leave their country, supplying the larger cities of Spain and Portugal with porters and servants, and the neighboring provinces with hands for the harvest. They return with their earnings after a longer or shorter absence, during which their wives perform the work in the house and the labor in the field. The chief towns are Corunna, the capital, Ferrol, Vivero, Pontevedra, Vigo, Mondonedo, Lugo, Santiago de Compostella (the ancient capital), and Orense.—Galicia was in antiquity the country of the Artabri and a section of Gallaecia. After the invasion of Spain by the barbarians, in the commencement of the 5th century, it shared for a time the fate of the larger part of the peninsula, being successively conquered by the Suevi, Visigoths, and Saracens. Ferdinand I. erected it into a kingdom for one of his sons, who was soon deprived of his throne and estates by Alfonso, king of Castile. Galicia was subsequently often held by the younger sons of the kings of Castile as an appanage, became independent in the course of time, and was finally annexed to his dominions by Ferdinand the Catholic.

GALILEE, the northernmost of the 8 western divisions of Palestine, divided into Upper and Lower Galilee. Upper Galilee was bounded N. by Mt. Lebanon, Coele-Syria, and the regions of Tyre and Sidon, W. by the Mediterranean sea, E. by the Jordan, and S. by Lower Galilee. This division was called Galilee of the nations, or of the gentiles, because of the mixed nature of its population. Lower Galilee was bounded N. by Upper Galilee, W. by the Mediterranean, E. by the lake of Tiberias or Gennesareth, and S. by Samaria. This division contained the tribes of Zebulun and Asher, and its inhabitants spoke a rude, corrupt dialect, different from that of the Jews, and were noted for their turbulent and rebellious spirit. Here Christ resided till he was 30 years of age, and first appeared to his apostles after his resurrection. The chief city of Upper Galilee was Cæsarea Philippi; of Lower Galilee, Tiberias.

GALILEO GALILEI (Galileo, by which he is commonly known, being his Christian name), an Italian philosopher and mathematician, born in Pisa, Feb. 15, 1564, died in Arcetri, Jan. 8, 1642. He came of a noble Florentine family, whose original name was Bonajuti, which they exchanged for that of Galilei about the middle of the 14th century. Vincenzo, the father of the philosopher, was a man of learning and the author of a number of treatises on music. Owing to his large family and his straitened circumstances,

he was unable to give his sons a thorough education, but Galileo acquired, amid various discouragements, a fair knowledge of the classics and the common branches of learning, beside attaining no mean proficiency in music, drawing, and painting. The last named art he seems to have resolved upon cultivating as a profession, but his father had other designs for him, and sent him to Pisa to study medicine, where he was matriculated at the university as a scholar in arts, Nov. 5, 1581, and became a pupil of the celebrated botanist Andreas Cæsalpinus. He still employed his leisure in his favorite branches of the fine arts, and his love of drawing led him to study geometry, in which he took such delight that medicine was neglected, and after many fruitless remonstrances his father was obliged to leave him to the natural bent of his genius. His first discovery was in 1582, when he was led to infer the isochronism of the vibrations of the pendulum by noticing the regular swinging of a lamp in the cathedral of Pisa. The principle does not rigorously hold true when the arcs of oscillation are long and very unequal, but though it was 50 years before the philosopher applied his discovery to clock work, he at once perceived its importance, and caused it to be employed by physicians in counting the pulses of their patients. Some time afterward, having read the treatise of Archimedes on floating bodies, he invented a hydrostatic balance, and wrote a description of it, which introduced him to the friendship of Guido Ubaldi, the mechanist and mathematician. A paper on the centre of gravity, composed at the instance of this distinguished man, was indirectly the means of securing for him at the age of 24 a professorship of mathematics in the university of Pisa. The salary was but 60 crowns, and he had to look for his support partly to private pupils. His native impetuosity at once found vent in attacking the notions of the Aristotelians; but though he fortified his arguments with careful experiments, the sarcasm and violence of his language raised him up a host of enemies, whose attacks pursued him for the rest of his life. He refuted the maxim that the velocity of falling bodies is proportional to their weight, by letting fall unequal weights at the same time from the top of the leaning tower of Pisa, explaining that the trifling difference of time noticed in their respective descents was owing solely to the resistance of the air. The death of his father in 1591 left him the duty of supporting the family, and soon after this the interest of Ubaldi procured him the appointment of professor of mathematics for 6 years in the university of Padua by the republic of Venice. This new position, upon which he entered in Sept. 1592, gave him a salary of 180 florins, beside enabling him to remove from a city where the hostility of the Aristotelians embittered his existence. He constructed for the use of the state several useful machines, and composed treatises on gnomonics, astronomy, mechanics, architecture, and even fortification, which he

delivered in the form of lectures. In 1597 he made a kind of thermometer in which both air and water were employed. It was during this period that he began a friendly correspondence with Kepler, which continued until the death of the latter; and about the same time appeared a treatise on the sphere after the Ptolemaic system, which has been attributed to Galileo on rather insufficient grounds. It was published from a MS. in the library of Somaschi at Venice (Rome, 1656). Probably between the years 1593 and 1597 Galileo became a convert to the Copernican theory of the revolution of the earth about the sun; but it is impossible to fix the date of this important event in his life, for he tells us in a letter to Kepler (1597), that in deference to public opinion he concealed his conviction of the truth of the new doctrines for some years after he had formed it. On the expiration of the term of his professorship, the Venetian senate appointed him for 6 years more, and raised his salary to 320 florins. In 1604, a new star of remarkable brilliancy having appeared in the constellation Serpentarius, he attacked the popular notion that it was a meteor, and proved by the absence of parallax that it was far beyond the limits of our system. In 1606 his appointment at the university was again renewed, with an addition of 200 florins to his compensation. The crowds that came to hear him were now so great that he sometimes had to lecture in the open air, and his reputation was equally high at home and abroad. In 1609 a report reached him at Venice, where he was then visiting, that a Dutchman had constructed an instrument which had the property of making distant objects seem near. Upon his return to Padua the philosopher immediately applied himself to the solution of the mystery, and after trying several combinations of lenses, succeeded in making an instrument which magnified 3 times. It consisted merely of a leaden tube—an organ pipe in fact—with a plano-convex glass at one end and a plano-concave at the other; but so elated was he with his imperfect work, that he carried it to Venice, where it at once became an object of the intensest public curiosity. He presented it to the senate, who thereupon confirmed him in his professorship for life, and raised his salary to 1,000 florins. Galileo soon constructed another telescope which magnified 8 times, and at length a third which had a power of 30. The wonders of the heavens now unfolded to him, which no man had ever seen before, filled him with "incredible delight." His earliest observations were upon the moon, whose inequalities of surface he was the first to trace. He saw myriads of stars in the milky way, counted 40 in the Pleiades, and at length, on Jan. 13, 1610, after 6 nights' observation, discovered the revolution of 4 satellites around the planet Jupiter. He did not publish this intelligence until by repeated examination, up to March 22, he had insured himself against the danger of mistake. The account of his discoveries, which he entitled

Nuncius Siderius, the "Sidereal Messenger," was received by the astronomers of the old school with insults and incredulity. Some exclaimed against the impiety of scooping out valleys from the fair face of the moon; some attempted to explain away the satellites of Jupiter as mere appearances caused by reflected light. A professor in the university at Padua argued that as there were only 7 metals, 7 days in the week, and 7 apertures in a man's head, so there could be but 7 planets; and when forced to admit the visibility of the satellites through the telescope, he reasoned that, being invisible to the naked eye, they were useless, and consequently did not exist. Several claimed a prior discovery of the "Jovian planets," and the astronomer Zach, as late as 1788, claimed for the Englishman Thomas Harriot the credit of having observed them on Jan. 16, 1610, some time before Galileo's discovery was made known. According to Sir David Brewster, however, Harriot did not perceive them until Oct. 17. The invention of the compound microscope is ascribed to Galileo, not without reason; Viviani, in his life of the philosopher, tells us that the telescope led Galileo to the construction of this instrument, and that he presented one of his microscopes to the king of Poland in 1612. The grand duke of Tuscany rewarded Galileo's services to science by a present of 1,000 florins, and by making him his philosopher and mathematician with a liberal salary and nominal duties. He now removed to Florence. To guard against future attempts to steal his laurels, he published his subsequent discoveries in enigmas, and thus in the course of the same year he announced that Saturn was "triple," an appearance which Huyghens subsequently showed was caused by that planet's rings. Galileo was the first to notice that Venus exhibits phases like those of the moon; and if not the first to descry spots on the sun's disk, he was at least the first to note their peculiarities, and to infer from them the sun's rotation. Some of these observations were made in 1611 at Rome, which he now visited for the first time, where he erected his telescope in the Quirinal garden belonging to Cardinal Bandini. He was received on this occasion with the highest honors, and became a member of the famous Lincean academy founded by Federigo Cesi near the beginning of the 17th century. In 1612 he combated in his work on the laws of floating bodies the common opinion that the tendency of substances to sink or swim in water depends on their shape. With this period in his life the philosopher may be said to have reached the zenith of his prosperity, while at the same time the malice of his enemies began to acquire a dangerous intensity. The Copernican system, which Galileo had long taught in public, afforded a good pretext for attacking him. The sun's revolution round the earth was thought to be a truth of Scripture. Certain Tuscan ecclesiastics began to preach against the wickedness of sending our world spinning through space, and a sarcastic Domini-

can hurled a sermon at Galileo from the text: *Viri Galilæi, quid statis adpicientes in cælum?* "Ye men of Galilee, why stand ye looking up into heaven?" In 1618 Galileo had addressed a letter to his pupil Castelli, showing that the language of the Bible should be interpreted according to popular ideas, and that the Ptolemaic system is really as much at variance with it as the Copernican. This was followed by one to Christina, grand duchess dowager of Tuscany, reiterating his views, and supporting them by quotations from the writings of the fathers. A Dominican, Lorini, laid a copy of the Castelli letter before the Roman inquisition in Feb. 1615, but the inquisitors refused to act in the matter, remarking that by confining himself to the system and its demonstration, and letting alone the Scriptures, Galileo would be secure from molestation. His enemies, however, continued their intrigues, and about the end of 1615 he went to Rome, either to obtain a formal sanction of his opinions, or, as some suppose, in obedience to a summons. His case came again before the holy office in Feb. 1616. He was charged with teaching that the sun is the centre of the planetary system, and interpreting Scripture to suit his own theory. The qualifiers of the inquisition pronounced the obnoxious doctrines "formally heretical, because expressly contrary to Holy Scriptures." Galileo's letters to Castelli and the grand duchess, Copernicus's work on the revolution of the heavenly bodies, and Kepler's epitome of the Copernican theory, were placed on the *Index Expurgatorius*, whence they were not removed until the time of Benedict XIV.; and Galileo himself, having failed in deference to the holy office, was obliged to promise never again to teach the motion of the earth and the stability of the sun either by speech or writing. He had a gratifying audience of the pope, however, who assured him of his protection, and in 1617 he returned to Florence. A sickness prevented him from observing the 8 comets which appeared in 1618, but he entered warmly into discussions about them, and is supposed to have had the chief share in a lecture delivered by his friend Guiducci and printed in 1619, in which those erratic bodies are held to be only meteors. This discourse was attacked by the Jesuit Grassi under the pseudonyme of Lotario Sarsi, and defended by Galileo in his *Saggiatore* ("Assayer"), one of the most beautifully written but least sagacious of his works. On the accession of his friend Cardinal Barberini to the pontificate under the title of Urban VIII., he went to Rome to offer his congratulations, arriving in the spring of 1624, and receiving during the 2 months that he remained every mark of esteem and liberality. The pope granted a pension of 100 crowns to him, and one of 60 crowns to his son. Encouraged, perhaps, by the friendly dispositions of the pontiff and the liberal declarations of some of the cardinals relative to the Copernican system, he set about composing a work in which he might sum up all the arguments for his favorite theory. It was

written in the form of dialogues, and accompanied by a preface which was doubtless the most imprudent thing that Galileo ever wrote. In it he treats the inquisition with contempt, charges it by insinuation with ignorance and passion, and covers the decision of 1616 with ridicule. Having ingeniously deceived the censors as to its real character, he managed to procure a license for his book, and it was accordingly published at Florence in 1682 under the title of "Dialogue on the two Principal Systems of the World, the Ptolemaic and Copernican." Such a violation of the injunction could not be overlooked. Galileo was ordered to appear in person at Rome, where he accordingly arrived in Feb. 1683, and took up his quarters with the Tuscan ambassador. His trial was short. The principal ground of complaint was the disobedience of the command of 1616, and the main defence which Galileo seems to have made was that in the years that had elapsed since then he had forgotten that the decree applied not merely to teaching the Copernican doctrine from the Scriptures, but to teaching it in any manner. The sentence was solemnly pronounced, June 22. It set forth the offence of the accused in teaching a condemned proposition, violating his pledge, and obtaining a sanction for his book by improper means, declared him to be vehemently suspected of heresy, required him to abjure his errors and all other heresies against the Catholic church, prohibited his "Dialogue," and condemned him to be imprisoned at the inquisition during pleasure, and to recite once a week for 3 years the 7 penitential psalms. Galileo made his abjuration with all the formality which commonly attended such proceedings. Clad in sack-cloth and kneeling, he swore upon the Gospels never again to teach the earth's motion and the sun's stability; he declared his detestation of the proscribed opinions, and promised to perform the penance laid upon him. Then rising from the ground, he is said to have exclaimed in an under tone: *E pur si muove*—"It does move for all that!" After 4 days' confinement under the eyes of the holy office, Galileo returned to the Tuscan ambassador's, but for the rest of his life he was kept under surveillance. He passed some time in Sienna, in the archbishop's palace, and in December reentered his own house at Arcetri, near Florence, where he remained until the close of his life. A fresh misfortune soon befell him in the death of his favorite daughter Maria, and this stroke so affected his already broken health that he begged permission to visit Florence for medical assistance. It was only after 4 years (1688) that he obtained it, and then under severe restrictions. He seems now to have paid little attention to astronomy, but other branches of natural philosophy engaged his intellect as successfully as ever. In 1688 his book of "Dialogues on Local Motion," completed 2 years before, which he prized above all his other works, was printed at Amsterdam by Louis Elzevir. In 1686 also he discovered the moon's diurnal libration. He next renewed

an attempt which he had made 20 years before to introduce a method of computing longitudes at sea by means of the satellites of Jupiter, but his negotiations on the subject with Holland failed, and indeed his method is now considered impracticable. In 1687 a disease which had impaired his right eye for some years attacked the left also, and in a few months he became totally blind. The severity of the inquisition was somewhat relaxed in his affliction; he was visited by eminent men of his own and foreign countries, among whom were Milton, Gassendi, and Diodati, and in the last years of his life his pupils Viviani and the celebrated Torricelli formed part of his household. Almost complete deafness afterward came upon him, and at last, while preparing for a continuation of his "Dialogues on Motion," he died of fever and palpitation of the heart.—In person Galileo was of middle size, well formed, with fair complexion and penetrating eyes. He was cheerful, frank, and amiable; frugal and abstemious, but fond of gay company and good wine, and profuse in his hospitality. His domestic life was neither virtuous nor happy. His temper was quick, but placable. His general accomplishments made him a favorite in mixed circles; but though he knew so well how to adapt his conversation to his company, he could not bend himself to circumstances when his favorite scientific theories were in question. Too eager for victory to judge well how to secure it, he damaged his own cause far more than the follies and prejudices which he had to combat. Nevertheless, astronomy owes to him, if not its richest inventions, at least some of its most brilliant discoveries. The telescope in the hands of his predecessors was a mere toy; in his hands it acquired such importance that he is often called its inventor. There was scarcely a part of mechanical philosophy which did not employ his genius with the grandest results, and his scientific writings were marked by a clear, elegant, and spirited style, which he owed to a careful study of the literature of his country. He was a great admirer of Ariosto, whose "Orlando Furioso," it is said, he knew by heart, and wrote severe "Considerations on Tasso" (Venice, 1793), to show that author's imitation of his favorite poet.—The following is a list of his principal works which were printed separately: *Operazioni del compasso geometrico e militare* (Venice, 1606); *Difesa contra alle calunnie ed imposture di Balt. Capra nella considerazione astronomica sopra la nuova stella del 1604* (1607); *Nuncius Siderius* (Florence, Venice, and Frankfort, 1610); *Discorso intorno alle cose che stanno in sul' acqua e che in quella si muovono* (Florence, 1612); *Epistola ad M. Velsorum de Maculis Solaribus* (1612); *De Maculis Solaribus et Stellis circa Jovem errantibus accuratior Disquisitio* (Augsburg, 1612); *Istoria e dimostrazioni intorno alle macchie solari e loro accidenti* (Rome, 1613); *Dissertatio de Cometa Anni 1619* (Florence); *Il saggiatore* (Rome, 1623); *Dialogo sopra i due massimi sistemi*

del mondo, Telemaco e Copernicano (Florence, 1632; a Latin translation by Bernegger, entitled *Systema Comicum* &c., Strasbourg, 1635; an English version, "The Systems of the World, in 4 Dialogues, Englished from the Original Italian Copy by Thomas Salusbury," London, 1661); *Discorsi e dimostrazioni matematiche attenenti alla meccanica ed i movimenti locali* (Leyden, 1638; an English translation under the title "Mathematical Discourses of Mechanics," by Thomas Weston, London, 1780); *Epistolæ tres de Conciliatione Sacra Scriptura cum Systemate Telluris Mobilis* (printed with Gassendi's *Apologia*, Lyons, 1649). Collections of Galileo's works were published at Bologna by Manolesi (2 vols. 4to., 1656); Florence, by Bottari (8 vols. 4to., 1718); Padua (4 vols. 4to., 1744); Milan (13 vols. 8vo., 1808). A complete edition was begun at Florence in 1842, and 12 vols. royal 8vo. had appeared in 1854.—For lives of Galileo see Viviani, *Vita del Galilei*, in the *Fatti consolari dell' accademia Fiorentina*; Frisi, *Elogio del Galileo* (Leghorn, 1775); Brenna, in Fabrina's *Vita Italorum*; Nelli, *Vita e commercio letterario di Gal. Galilei* (2 vols. 4to., Lausanne, 1793); Libri, *Histoire de la vie et des œuvres de Galil. Galilei* (Paris, 1841); Biot, in Michaud's *Biographie universelle*; Drinkwater, "Life of Galileo," in the "Library of Useful Knowledge;" Sir David Brewster, in Lardner's "Cabinet Cyclopædia," reprinted with lives of Tycho Brahe and Kepler under the title "Martyrs of Science" (London, 1841).

GALLOT, the smallest kind of galley, without guns, used chiefly in the Mediterranean. It is designed only for chase, and has both sails and oars. The name is also given to a peculiar flat-bottomed vessel, strongly built, and used as a bomb ship against forts and batteries. A kind of merchant vessel, strong and clumsy, used by the Dutch, Swedes, and other northern nations, is also termed a galiot.

GALL, FRANZ JOSEPH, the founder of phrenology, born in Tiefenbronn, near Pforzheim, in Würtemberg, March 9, 1758, died at Montrouge, near Paris, Aug. 22, 1828. His father, of Italian origin, was a merchant, and he was first prompted to study by his uncle, a neighboring curate. After literary studies at Baden and Bruchsal, he devoted himself especially to natural history and anatomy at Strasbourg under Hermann, and passed thence in 1785 to the medical school of Vienna, where he attended the lectures of Van Swieten and Stoll, and received the degree of doctor in 1785. He gradually obtained success in the practice of his profession, with leisure, however, for gardening and study. While a boy he had been struck with the differences of character and talents displayed by his companions, and after some time he noticed that those students who excelled in committing pieces to memory all had large eyes. By degrees he suspected that the external peculiarities of the head corresponded with differences in the intellectual endowments and moral qualities, and disputed the theories of Aristotle, Van Helmont, Des-

cartes, and Drelincourt, who fixed the soul respectively in the heart, the stomach, the pineal gland, and the cerebellum. He began diligently to examine the heads of those who had exhibited any striking mental peculiarity; the lunatic asylum gave him opportunities to make observations on monomaniacs; he visited prisons, courts of justice, and seats of learning; and whenever he heard of a man remarkable for either good or evil, he made his head a study. He extended his observations to animals, and finally sought confirmation in the anatomy of the brain, of which he was the first to perceive the true structure. After 20 years he conceived that he had determined the intellectual dispositions corresponding to about 20 organs, that he had found the seats of these original faculties in the brain, and that they formed prominences or protuberances on the skull proportionate to their degree of activity. In 1791 he published the first volume of a general medical work, and in 1796 began to lecture on his peculiar theory in Vienna, where the novelty of the views made a great sensation. The first written account of them appeared in a letter published in the *Deutscher Mercur* of Wieland in 1798. In 1800 he gained his best disciple, Spurzheim, who gave great aid in the development and popular exposition of the doctrine. Dr. Gall continued his lectures till in 1802 they were interdicted by the Austrian government as dangerous to religion. He quitted Vienna in 1805, and in company with Spurzheim, who was his associate till 1813, travelled in central and northern Europe, lecturing in the principal, especially the university towns, and arrived in Paris in 1807. He established himself as a medical practitioner, and immediately delivered a course of lectures before a numerous audience. His principles, however, met with much opposition; ridicule was not spared, and Napoleon opposed him and classed him with Cagliostro and Mesmer. He presented to the institute in 1808 his *Recherches sur le système nerveux en général, et sur celui du cerveau en particulier*, and published it in the following year. In 1821 his name was proposed for the academy of sciences, but he obtained only the vote of the friend who had counselled the step, Geoffroy St. Hilaire. In 1823 he made a short visit to London, where the receipts from his lectures were less than the expenses. The most elaborate of his works is the *Anatomie et physiologie du système nerveux* (4 vols., Paris, 1810-'19), a second edition of which was published in 6 vols., each bearing a different title. An English translation of the whole work by Winslow J. Lewis, Jr., M.D., was published in Boston (6 vols., 1835).

GALL BLADDER, the pear-shaped membranous reservoir, situated in a slight depression on the lower surface of the right lobe of the liver, which contains the bile during the intervals of digestion. The larger extremity is directed forward and to the right side; the body of the organ is adherent above to the substance of the liver by dense areolar tissue, free below,

covered by the peritoneum, and resting upon the pylorus, duodenum, and right arch of the colon; the neck is narrow and continuous with the cystic duct, about an inch and a half long, which unites with the hepatic duct from the liver, of about the same length, to form the common bile duct (*ductus communis choledocus* of anatomists). It is composed of an external serous coat, a middle areolar contractile tissue, and an internal mucous membrane; the arteries are derived from the hepatic branch of the coeliac axis, the nerves from the hepatic plexus, and the veins empty their contents into the vena portæ. The hepatic duct is formed by the junction of the 2 principal branches (one from each lobe), the result of the union of the numerous ramifications from the interior of the liver; during digestion the bile flows without obstruction into the duodenum, but in the intervals of this process the intestinal orifice of the common duct is closed, and the bile flows by the cystic duct backward into the gall bladder, whose office is essentially that of a reservoir, enabling the bile to be constantly secreted, and insuring a supply for the service of digestion. The common duct is formed by the union of the hepatic and cystic ducts, and is about $3\frac{1}{4}$ inches long, opening obliquely into the duodenum near its last curve, by an orifice in the middle of a slight elevation. The stimulus of the food opens the intestinal orifice, and bile is discharged both from the liver and the gall bladder during digestion, its passage being effected by the contraction of the walls of the gall bladder and the ducts. Ordinarily containing a few ounces, the gall bladder may be so distended as to contain several pints, and it may be so atrophied as to be little larger than a pea; these cases, and the fact of the absence of the reservoir in many animals, show that its physiological importance is not very great. It is subject to ossification, cancer, acute and chronic inflammation from the irritation of gall stones or extension of diseases from the intestine; its diseases may end in ulceration, and obliteration of the ducts. From its small size and protected situation it is rarely directly wounded, though it is sometimes ruptured by great external violence. The gall bladder is absent in invertebrates, in which the bile ducts open directly into the digestive cavity; it is present in most fishes, all reptiles, and most birds. There seems to be no general law regulating its presence or absence in mammalia; it is wanting in many rodents (as the mice), in the elephant, rhinoceros, tapir, camel, peccary, horse, stag, and dolphin; it is present in the monkeys, bats, carnivora, almost all edentates, and in many ruminants (as the ox, sheep, goat, and antelope). In the cats there are sometimes 2 gall bladders. With the exception of the dolphins, it seems that all mammals in which it is absent are vegetable feeders.

GALL INSECTS, various genera belonging to the orders *hymenoptera* and *diptera*, which deposit their eggs in the tissue of plants, producing excrescences or galls upon them, in the

interior of which their young are brought to maturity. The insects which produce the nut galls of commerce, used in dyeing and the manufacture of ink, are *hymenoptera* of the genus *cynips* (Linn.) or *diplolepis* (Geoffr.); they are small, with 4 wings, the anterior long and with a single or few nervures, the posterior small and veinless; the head is small, the antennæ short and slender, the thorax thick and elevated, the abdomen sharp-edged above and below, and attached to the thorax by a very slender stem; the females are provided with a long slender ovipositor, attached near the origin of the abdomen, whose curvature it follows, and contained between 2 sheath-like pieces which serve to conduct the eggs into the hole made by the piercer; they constitute the family *cynipide*. The wounds made in the plant are followed by swellings which increase rapidly, becoming spongy within; these galls partake of the chemical character of the juices, and on the oaks are highly astringent; the eggs dropped into the punctures grow by the absorption of the surrounding sap, and the grubs when hatched find themselves surrounded by an ample supply of food, and finally gnaw out of the gall when they arrive at maturity; the grubs resemble maggots, of a whitish color, and are without proper legs. Each species of gall fly generally confines itself to one sort of plant, and always produces galls of the same kind; hence there are almost as many kinds of galls as there are species of gall flies. Some of these excrescences are irregular and uneven, others round and smooth; some hang by small stems, others are flat, applied either to the wood or leaves; soft at first, they become hard and woody. The insect which produces the nut gall used in medicine and the arts is the *C. gallæ tinctoriæ* (Geoffr.), which pierces the dyer's oak, a native of the middle latitudes of Asia; the body is fawn-colored, the upper part of the abdomen shining brown, and the antennæ dark; a single insect usually inhabits each gall. The *C. confluentus* (Harris) of America is nearly $\frac{1}{2}$ of an inch long, with an expanse of wings of $\frac{3}{4}$ of an inch; the head and thorax are black, roughened by hairs, the hind body smooth and of a shining pitch color, the legs brownish red, and the fore wings with a brown spot. It pierces the leaves of the red oak, and the swellings (or oak apples) measure $1\frac{1}{2}$ to 2 inches in diameter; green and soft at first, they become hard-shelled and drab-colored, inclosing a quantity of brown spongy matter, and a central woody kernel as large as a pea; the grub becomes a chrysalis in the autumn, when the oak apple falls to the ground, and it changes to a fly in the spring, though it sometimes comes out a perfect insect in October. Most species of oak are susceptible to this kind of action; our white oak has its small twigs pierced by the *C. oneratus* (Harris), a small species only $\frac{3}{8}$ of an inch long, which produces clusters of galls about the size of bullets, greenish on one side and red on the other. The *C. nubilipennis* (Harris), with a smoky tip to the wings, causes

galls of the size and color of grapes. There are many other gall-producing insects, and the excrescences found on oaks in the United States are different from those of Europe. Rose bushes are attacked by the *C. bicolor*, *dichlo-cerua*, and *semipiceus*. All such galls on plants of any value should be cut off and burned; many of these gall insects are destroyed in the grub state by parasitic *hymenoptera* of the family *chalcididae*.—There are several dipterous insects which produce unnatural enlargements of the stems of plants, especially in the genus *cecidomyia*, or gall gnats. The willow gall fly (*C. salicis*, Fitch) is about $\frac{1}{2}$ of an inch long, of a deep black color above, paler and downy beneath; its galls are found on the ends of the slender twigs of the American basket willow (*salix rigida*) and other dwarf species, of an oval shape, about $\frac{3}{4}$ of an inch long and $\frac{1}{4}$ of an inch thick, terminated by a brittle conical beak; when cut open in winter or spring, in a longitudinal silk-lined channel will be found an orange-colored maggot $\frac{1}{2}$ of an inch long; this becomes a pupa in the course of the spring, of a blood-red color, without any shedding of the larval skin. The *C. robinia* (Hald.) is a smaller species, thickening the edges of the leaves of the locust tree. Other *diptera* of the family *ortulididae* deposit their eggs in the stems, buds, and leaves of plants, producing excrescences or galls in which the young reside; swellings thus caused, as large as walnuts, are sometimes seen on the stalks of asters or starworts; it is the *tephritis asteris* (Harris), about $\frac{1}{2}$ of an inch long, of a light yellowish brown color, with paler legs.

GALL NUTS. See GALLIA.

GALL STONES, or BILIARY CALCULI, the concretions formed from the elements of the bile, situated most frequently in the gall bladder, but found also in the liver and its ducts, whence they pass into the intestines and are often discharged from the body. The most common form of these stones consists principally of cholesterine, a crystallizable fatty ingredient of healthy bile, whose chemical constitution is $C_{27}H_{45}O_2 + 2Aq$; according to Berzelius, it does not exceed in quantity one part in 10,000 in the bile; taurocholic acid (choleic acid of Strecker) possesses a certain solvent power over it, and holds it in solution; owing, however, to its extreme insolubility, when once deposited it cannot be reabsorbed, and hence often accumulates in the gall bladder. Cholesterine gall stones have a crystalline structure, fuse at a heat of $298^{\circ}F.$, and have sometimes less specific gravity than water; they vary considerably in shape and appearance, in some cases nearly semi-transparent and crystallized throughout, in others strongly tinged with the coloring matters of the bile, or formed of concentric layers on a nucleus of phosphate of lime. Their forms are generally rounded, and worn by attrition one against the other; their size varies from a fine sand to the volume of a hen's egg, the usual dimensions being about $\frac{1}{2}$ to $\frac{1}{4}$

inch in diameter; Meckel has described one $5\frac{1}{2}$ inches long and $4\frac{1}{2}$ in circumference, weighing $1\frac{1}{2}$ oz. They are rarely single, and are often found several hundreds together; the color is light in proportion to the amount of cholesterine in their composition, and dark in proportion to the amount of the green coloring matter of the bile. They are most common in old persons, and especially in the female sex; it is very rare to examine the hepatic system of aged females without finding more or less gall stones; under the age of 12 years they are very uncommon. The formation of these concretions, which vary much in hardness as well as in size and number, has been attributed to irritation of the gall bladder and its ducts, and to the retention of the bile from inertia of its walls, the position and tortuous character of the ducts, and the consequent deposition of the elements of the bile; but as cholesterine, the principal ingredient of these stones, is a normal constituent of the blood, and is present in the brain and in various natural and diseased exudations, it is more likely dependent on some ill-understood but ever-acting vital chemical changes, as yet beyond the ken of organic chemistry.—The presence of gall stones is not necessarily indicated by any special or painful symptoms, and their existence in considerable numbers is not incompatible with good health and long life; when of large size, or obstructing the flow of bile in any direction, there may be pain, tenderness, swelling, vomiting, jaundice, and constipation. When a stone of large size or irregular shape is impacted in any of the ducts, the pain may be intense, causing what is called hepatic colic, accompanied with fever and inflammatory symptoms; this agony continues until the patient is stupefied by narcotics, or the stone has passed into the alimentary canal, whence it is removed by the stools, or in some cases by vomiting. A stone may become enlarged in the intestines, and cause a fatal obstruction; it is said that Loyola, the founder of the Jesuits, came to his death by the passage of a stone from the gall bladder by perforation into the vena portæ. The pathognomonic signs of these stones are the passage of one or more from the intestine, and the sound of friction or crepitation when the gall bladder is suddenly compressed by the hand; if to these be added frequent accessions of pain and heaviness in the right hypochondrium, with jaundice, the diagnosis is greatly assisted. If inflammation arises in the organ, adhesions may take place, and the stones may safely pass into the intestines, or externally through the abdominal walls. The indications of treatment are to relieve pain and spasmodic action of the ducts, to cause the solution or evacuation of the stones, and to arrest any accompanying inflammation which may arise. The first indication was formerly met by the free exhibition of narcotics, especially opium, and by the external application of fomentations and refrigerants; of late years, the inhalation of sulphuric ether has been found to answer the purpose in a complete, rapid, and

safe manner. To fulfil the second indication, gross animal or salted food, acrid vegetables, and spirituous liquors are forbidden, and an opposite diet with ferruginous mineral waters recommended; mixtures of sulphuric ether and spirits of turpentine were believed to have the property of dissolving biliary concretions; emetics were given to cause their expulsion by the contractions of the diaphragm and the consequent concussions of the organs, and powerful cathartics to insure the removal of any that might be lodged in the intestines. Any complicating inflammation is treated on general principles. It has sometimes been found necessary to procure adhesion of the gall bladder to the abdominal walls by caustic potash, and then to remove the stone by the knife or by caustic; persons have lived for years with fistulæ communicating with the gall bladder, without any apparent suffering in health. Alkaline solutions have without sufficient reason been regarded as the most likely to dissolve gall stones.

GALLAGHER, WILLIAM D., an American journalist and poet, born in Philadelphia in 1808. He removed in 1816 to Cincinnati, where in 1825 he entered the printing office of a newspaper. He wrote occasionally for the press, and became editor successively of the "Backwoodsman," at Xenia, O. (1830), the "Cincinnati Mirror" (1831), the "Western Literary Journal and Monthly Review" (1836), the "Hesperian, a Monthly Miscellany of General Literature" (1838), and in 1839 associate editor of the "Cincinnati Gazette," in which position he remained till 1850. He published 3 small volumes of poetry (1835-'7), each entitled "Erato," the principal pieces in which are the "Penitent," the "Conqueror," and "Cadwallen." In 1841 he published a volume of "Selections from the Poetical Literature of the West," and in 1846 a select edition of his poems. When Thomas Corwin became secretary of the treasury in 1850, Mr. Gallagher accompanied him to Washington as his confidential clerk. In 1853 he removed to Louisville, Ky., and was for a time one of the editors of the "Daily Courier," but has since resided on a farm near the city.

GALLAIT, LOUIS, a Belgian historical painter, born in Tournay in 1810, spent several years in studying his art in Paris. Among his pictures most celebrated and popular in Belgium is one illustrating the last honors paid to Egmont and Horn after their execution, which has been purchased by his native city, and one representing the last moments of Egmont (1853). His "Abdication of Charles V." is in the court of casation of Brussels, and his "Montaigne visiting Tasso" is in the possession of King Leopold. His "Temptation of St. Anthony" has been presented by Leopold to Prince Albert. Most of his pictures have been exhibited and much admired in Paris; some of them are at Versailles and in the Luxembourg. He is now (1859) completing his great tableau of "Dalla."

GALLAND, ANTOINE, a French antiquary

and linguist, born near Montdidier, in Picardy, April 4, 1648, died in Paris, Feb. 17, 1715. In 1670 he became attached to the French embassy at Constantinople, visited Jerusalem, and copied there a great number of inscriptions, several of which Montfaucon published in his *Paleographia Græca*. Returning to France in 1675, he subsequently made two voyages to the Levant to collect medals, coins, &c. He was afterward appointed antiquary to the king. In 1709 he was appointed professor of Arabic in the royal college of France. His works are very numerous, but the most popular of them all perhaps is his translation into French of the "Tales of the Thousand and One Nights" (12 vols., Paris, 1704-'17), the famous "Arabian Nights' Entertainments," which he was the first to introduce to the knowledge of Europe. For some time they were thought to be inventions of his own.

GALLAS, a race of E. Africa, comprising a number of tribes inhabiting the imperfectly explored region to the west, south, and east of Abyssinia, bordering on the country of the Danakil, Harrar, the Somaui, and the countries of Zendero, Guragne, Caffa, and Enarea. They are also found in various parts of Abyssinia, where they have made extensive conquests. They seem to hold an intermediate place between the Arabian and negro races. Their color is dark brown, their hair strong and frizzled, though not exactly woolly, their eyes are small, features thick and flattened, faces round, and persons generally large and well formed. They are mostly pastoral in their mode of life, although some of the tribes bordering on Abyssinia are tillers of the soil. Mohammedanism has made converts among them, but the majority of the tribes adhere to paganism. Their religion is said to resemble that of the Caffres. They worship a supreme incomprehensible being whom they call Wak, and who manifests his will by dreams and omens, of which priests are the interpreters. These priests, who, according to Major Harris, are divided into 2 orders, sacrificers and sorcerers, carry with them a whip and bells, and the intestines of goats wound about their necks; these last implements of priestcraft are their favorite means of divination. The Gallas pray occasionally to their god, believe in a future state of reward or punishment, and the males of all the pagan tribes, however differing in other respects, make pilgrimages to a sacred tree on the banks of the Hawash, south of Shoa. A remarkable resemblance of the Galla religion in some points to Christianity was pointed out by Dr. Beke in the "Friend of the African" (vol. i., 1844), and seems to justify the belief that at some remote period they had a knowledge of the Christian faith. Their language bears affinity to the languages of the Somaui and Danakil. The word Galla in their tongue signifies invader, and the name by which they designate all their tribes in common is Oroma (*orma*, men). The tribes are independent of each other, some observing a patriarchal form of government, and

some being ruled by females. The origin of this people has been much disputed. Some supposed them to be descendants of whites belonging to the Hebrew nation, and derive their name from the Hebrew *halab*, milk—an allusion to their original color. Others believed them to be Meccan Arabs who settled on the W. coast of the Red sea at a very early period. Dr. Beke places their cradle far S. of Abyssinia, and probably in the mountainous country near the sources of the Nile. It seems certain that they are of negro race, and that their original territory is some distance S. of that which they now occupy. The Abyssinians trace the origin of the Gallas to an Abyssinian princess who was given in marriage to a slave from the country S. of Gurgue, and had 7 sons who became mighty robbers and founders of tribes. They invaded and settled in Abyssinia as early as 1537, and have continued their conquests and appropriations until they are now in possession of the fairest portions of that country.

GALLATIN. I. A. N. co. of Ky., separated from Indiana by the Ohio river; area estimated at 150 sq. m.; pop. in 1850, 5,137, of whom 704 were slaves. It is diversified by well wooded hills, and abounds in blue or Trenton limestone. The productions in 1850 were 402,150 bushels of Indian corn, 27,388 of wheat, and 198,095 lbs. of tobacco. There were 6 churches, 1 newspaper office, and 880 pupils attending public schools. Value of real estate in 1855, \$1,000,623. Capital, Warsaw. II. A. S. E. co. of Ill., drained by Saline creek, separated on the E. from Kentucky by the Ohio river, and from Indiana by the Wabash; area, 810 sq. m.; pop. in 1855, 6,728; in 1858, about 8,500. It consists mostly of forest land, has a fertile soil, and contains valuable salt springs. The staples are horses, cattle, swine, lumber, tobacco, and salt. The agricultural products in 1850 were 436,125 bushels of Indian corn, 25,987 of oats, 200 lbs. of tobacco, and 47,622 of butter. There were 7 churches, 1 newspaper office, and 555 pupils attending public schools. A railroad has been projected from Vincennes to Paducah, which will pass through the county. Capital, Equality. Organized in 1812.

GALLATIN, ALBERT, an American statesman, born in Geneva, Switzerland, Jan. 29, 1761, died in Astoria, Long Island, N. Y., Aug. 12, 1849. His original name was Abraham Albert Alphonse de Gallatin. His father, Jean de Gallatin, was a councillor of state. His parents, who were both of ancient and distinguished noble families, numbering among their connections the celebrated Necker and his daughter Madame de Staël, died while he was an infant. To the care of a female relative of his mother he owed an excellent education, which was completed at the university of Geneva, where he was graduated in 1779. At the university he gained the friendship of the young landgrave of Hesse-Cassel, who offered him a commission as lieutenant-colonel, which he declined, his republican principles and his sympa-

thy with the Americans in their revolutionary struggle impelling him to prefer, like Lafayette, to cross the Atlantic and volunteer his services to the cause of liberty. Early in 1780 he embarked for Boston in a vessel which by stress of weather was compelled to put into one of the harbors of Cape Ann. At a tavern on the cape near where he landed he found some Swiss from Geneva who knew his family. They were on their way to Machias, in Maine, where they intended to settle. He was easily persuaded to accompany them thither. On his arrival at Machias he found Capt. John Allen, the commandant of the fort, employed in raising volunteers for the defence of Passamaquoddy. Gallatin offered his services, and marched with the volunteers to the frontier, assisting them to drag a heavy cannon over swamps and muddy roads. He was soon appointed commander of the fort of Passamaquoddy, which was garrisoned by a small force of volunteers, militia, and Indians. The troops being in great want of supplies, he advanced \$600 out of his own pocket, for which he received from Allen an order on the treasury of the United States. In Oct. 1780, he went to Boston, and on presenting his order found that there was no money in the treasury. His necessities compelled him to sell the draft for about one third of its nominal value. Soon after reaching Boston, with a fondness for geographical investigations that distinguished him through life, he made a series of excursions in different directions, in one of which he ascended Wachusett mountain, the highest in Massachusetts east of the Connecticut. In 1788 he was for a short time teacher of French at Harvard college, and in the following year, having received from Europe his patrimonial property, he went to Virginia and purchased a large tract of land in the western part of that state for the purpose of forming a settlement, from which he was deterred by the hostilities with the Indians. While surveying these lands he first met with Washington, who also owned large estates in that region. Washington was seated in a land agent's log cabin, surrounded by a number of squatters and hunters, whom he was examining with a view to ascertain the best route for a road across the Alleghanies. Gallatin mingled with the throng and stood looking on for some time, while Washington put his questions with slowness and deliberation, and carefully noted down the answers. It was soon evident to the quick-minded Swiss that there was but one practicable pass; and after the testimony had abundantly settled the point, he grew impatient at Washington's slowness in coming to a conclusion, and suddenly interrupting the general's cross examination, cried out: "Oh, it's plain enough that [naming the place] is the most practicable." The by-standers stared with astonishment at the presumptuous youngster, and Washington, laying down his pen, looked at him sternly for a moment in evident displeasure, but did not speak. Presently he resumed his pen, put a

few more questions to the man he was examining, then suddenly threw down his pen, and, turning to Gallatin, said: "You are right, sir." "It was so on all occasions," said Gallatin to Mr. John Russell Bartlett, to whom, more than 60 years afterward, he related the anecdote; "Gen. Washington was slow in forming an opinion, and never decided until he knew he was right." After Gallatin went out, Washington inquired about him, and, learning his history, made his acquaintance, and urged him to become his land agent. Gallatin, however, declined the situation, and in 1786, by the advice of Patrick Henry, he purchased some land on the banks of the Monongahela in Fayette co., Penn., settled there, became naturalized, and devoted himself to agriculture. In 1789 he was elected a member of the convention to revise the constitution of the state, and in the two succeeding years was a member of the legislature, to which he was chosen as the candidate of the republican or democratic party. In the latter body he proposed measures to resuscitate the credit of Pennsylvania which gave strong indications of the financial abilities which he afterward displayed so conspicuously in the administration of the federal treasury. In 1793 the legislature elected him U. S. senator. He took his seat, but his right to it was contested, and at the end of two months it was decided by a strict party vote of 14 federalists to 12 democrats that he was ineligible. The constitution requires that a senator should have been 9 years a citizen. It was contended by the democrats that the 9 years' citizenship began with Gallatin's arrival in Massachusetts in 1780; but the federalists maintained that it did not begin until he took the oath of allegiance in 1785. The legislature of Pennsylvania acquiesced in the decision, and chose James Ross in Gallatin's place. In 1794, during the recess of congress, the disturbance known as the "whiskey insurrection" broke out in western Pennsylvania; its object was resistance to the excise laws. Gallatin took part in the peaceful political opposition to the excise, and afterward, on Aug. 1, 1794, acted as secretary of a great meeting of armed men collected by the leaders of the insurrection. He also acted as secretary of a delegate convention of the same party assembled Aug. 14 at Parkinson's Ferry, and subsequently was one of a committee appointed by the insurgents to propose terms to the government. His object, however, in mingling with these transactions, was to exert his influence to suppress the insurrection, and to bring about a peaceful accommodation between the government and the people. This was finally effected, in great part by Gallatin's tact, courage, and firmness, at considerable personal risk to himself. So highly were his services in the cause of order estimated in his own neighborhood, that the people of a district adjoining that in which he resided, comprising Washington and Alleghany counties, nominated him without his knowledge for representative to congress, on the express ground of his successful management of

the excise difficulties, and elected him 8 days after his nomination over the regular candidates of both political parties. For 3 terms in succession he was reelected from the same district. He entered congress in Dec. 1795, and soon took a high position in debate and legislation, and was recognized as the leader of the republican or democratic party, though Madison and other able and experienced men of the same party were in the house with him. By a speech delivered April 26, 1796, in opposition to the British treaty, during the great debate on that question, he established beyond all dispute his reputation as a dexterous and unflinching politician, though the tone he adopted greatly exasperated the federalists, who could not patiently listen to denunciation of Washington and Jay as having pusillanimously surrendered the honor of their country, coming as it did, says Hildreth, "from the mouth of one whose evident youth and foreign accent might alone serve to betray him as an adventurer, whose arrival in the country could hardly have been long anterior to the termination of the revolutionary struggle." A leading federalist, Mr. Tracy of Connecticut, replied to Gallatin, and in the course of his speech remarked that "he could not feel thankful to any gentleman for coming all the way from Geneva to accuse Americans of pusillanimity." Two days later, Fisher Ames made his great and decisive speech in favor of the treaty. In the course of the debate Gallatin made a speech on the resolution calling on the president for Jay's correspondence, which Jefferson in a letter to Madison declared was "worthy of being printed at the end of the 'Federalist,' as the only rational commentary on the part of the constitution to which it relates." In every important debate that took place while he was in congress Gallatin participated with vigor and effect, though his favorite topics were such as related to financial questions. It was on his motion that the committee of ways and means was first organized as a standing committee of the house in 1796. He explained his financial views in two pamphlets, "A Sketch of Finances" (1796), and "Views of Public Debt," &c. (1800). Beside his speeches on the British treaty, he made important speeches on "Foreign Intercourse," March 1, 1798; on the "Alien Law," March 1, 1799; and on the "Navy Establishment," Feb. 9 and 11, 1799. On May 15, 1801, he was appointed by President Jefferson secretary of the treasury, which office he held through 3 presidential terms, under Jefferson and Madison, till 1813. He was eminently successful in his management of the treasury department, and soon attained a distinguished reputation as one of the first financiers of the age. His annual reports exhibit great ability, and had the highest influence upon the general legislation of the republic. He opposed the increase of the national debt, and prepared the way for its gradual extinction. He systematized the mode of disposing of the public lands, and was a zealous advocate of internal improvements, and particularly of the national

road and of the coast survey. He also exercised great influence on the other departments of the government, and on the politics of the country. In 1809 President Madison offered him the state department, which he declined, preferring to remain at the head of the treasury. He was opposed to going to war with Great Britain in 1812, and as a member of the cabinet exerted himself strenuously to restore amicable relations with the British government. An offer having been made by the Russian government to mediate between the United States and Great Britain, President Madison, March 8, 1813, nominated as ministers to negotiate, Gallatin, James A. Bayard of the senate, and John Quincy Adams, at that time American minister at St. Petersburg. Gallatin and Bayard in May sailed for St. Petersburg in a private ship, with a cartel from the British admiral, granted at the request of the Russian ambassador at Washington. The appointment of these commissioners had been made during the recess of congress. In a few weeks the senate came together in a called session, when great opposition was made to Gallatin's confirmation, on the ground that a diplomatic appointment was inconsistent with the headship of a department, it appearing that Gallatin still remained secretary of the treasury, an arrangement having been made by which, during his absence, the duties of his office were discharged by the secretary of the navy, under an act of 1792 which allowed such temporary substitutions. The senate, after discussion, rejected Gallatin as commissioner by a vote of 18 to 17. The attempt at Russian mediation resulted in nothing, but in Jan. 1814, an offer was received from the British government proposing a direct negotiation for peace at London or Gottenburg. Selecting Gottenburg as the place, President Madison nominated as commissioners John Quincy Adams, Henry Clay, Jonathan Russell, Bayard, and Gallatin. Gallatin was still abroad, and to obviate the objection of the senate on account of his holding the office of secretary of the treasury, he resigned that post definitively, and a successor was appointed. It was finally decided that the negotiations should be conducted at Ghent. In the discussions which resulted in the treaty of peace, Dec. 24, 1814, and in the commercial convention with Great Britain a short time afterward, Gallatin had a prominent and honorable share. In 1815 he was appointed minister to France, where he remained until 1823. During this period he was twice deputed on special missions of importance, to the Netherlands in 1817 and to England in 1818. While in this office he rendered some essential service to Mr. Alexander Baring in the negotiation of a loan for the French government. Mr. Baring in return pressed him to take a part of the loan, offering him such advantages in it that without advancing any funds he could have realized a fortune. "I thank you," was Gallatin's reply; "I will not accept your obliging offer, because a man who has had the direction of the finances of his country as long as I have

should not die rich." On his return from France he refused a seat in the cabinet, and declined to be a candidate for vice-president, to which he was nominated by the democratic party. In 1826 he was appointed by President Adams envoy extraordinary to Great Britain. After negotiating several important commercial conventions, he returned to the United States in Dec. 1827, and took up his residence in the city of New York. Soon after his return he prepared the argument in behalf of the United States to be laid before the king of the Netherlands as an umpire on the Maine boundary question. In 1830 he was chosen president of the council of the university of New York. In 1831 he published "Considerations on the Currency and Banking System of the United States," in which he advocated the advantages of a regulated bank of the United States. He was a member of the free trade convention at Philadelphia in 1831, and prepared for that body the memorial which was submitted to congress. From 1831 to 1839 he was president of the national bank in the city of New York, and on his resigning the office was succeeded by his son James Gallatin. The remainder of his life was devoted to literature, and especially to historical and ethnological researches. He was elected president of the New York historical society in 1843, and held the office till his death. In the previous year he had been one of the chief founders, and was chosen first president of the ethnological society. During the controversy with Great Britain on the north-eastern boundary he published an able pamphlet on the subject, which displayed great research. Again, in 1846, during the Oregon difficulties, he published letters on the "Oregon Question," distinguished by impartiality, moderation, and power of reasoning. He was strongly opposed to war, and two years later, during the war with Mexico, he wrote a pamphlet of which 150,000 copies were printed, and which had a marked influence on public opinion. At an early period Mr. Gallatin turned his attention to the ethnological and philological characteristics of the American Indians. His first essay on this topic was written in 1823 at the request of Humboldt. He afterward published "Synopsis of the Indian Tribes within the United States, east of the Rocky Mountains, and in the British and Russian Possessions in North America," forming vol. ii. of the *Archæologia Americana* (American antiquarian society, Worcester, 1836); and the subject was one of the last that occupied his pen, in a work on the "Semi-Civilized Nations of Mexico, Yucatan, and Central America," with "Conjectures on the Origin of Semi-Civilization in America" (American ethnological society, New York, 1845). A French biographer of Gallatin, M. Feillet, remarks that his career was one of the happiest and most successful that ever fell to the lot of man. From the position of a friendless adventurer in a strange land he speedily raised himself by force of talent and energy to fame and power, filled with distinction the highest

offices, and after half a century of public service passed an honored and serene old age in study and in the cultivation of literature and science. "Mr. Gallatin," said Judge Story in a letter to a friend, "preserved a purity of character that is as valuable in a politician as it is rare. He is a most industrious and indefatigable man, and, by the consent of all parties, of accomplished genius and great acquirements. Let me say he is a truly great statesman. I rank him side by side with Alexander Hamilton."

GALLAUDET, THOMAS HOPKINS, LL.D., founder of the first institution in America for the instruction of the deaf and dumb, born in Philadelphia, Dec. 10, 1787, died in Hartford, Conn., Sept. 9, 1851. He was of Huguenot descent, early removed with his parents to Hartford, and was graduated at Yale college in 1805. He was successively a student of law, tutor in the college, and clerk in a counting-room, till in 1811 he entered the theological seminary at Andover, to prepare for the ministry. He was licensed to preach in 1814, but immediately became interested in the instruction of deaf mutes, and was appointed to superintend the establishment of an institution at Hartford for that purpose. To further this project, and to learn the best method of instruction, he went to Europe in 1815, visited London, Edinburgh, and Paris, and returned in the following year with Laurent Clerc, a highly educated deaf mute, who had been a favorite pupil of the abbé Sicard, and a teacher in the Paris institution. Meantime the asylum for the deaf and dumb had been chartered at Hartford, a building was in process of erection, and it went into operation in 1817 with a class of 7 pupils. Dr. Gallaudet retained his connection with it as principal till his resignation on account of impaired health in 1830, after which he continued to be one of the directors. More than 1,000 persons were educated at the asylum during his lifetime, which became also the parent of similar institutions in other parts of the country. After a short respite from his labors, he engaged again in philanthropic efforts, prepared various works to aid the education of the young, and in 1838 became chaplain of the Connecticut retreat for the insane, at Hartford, which office he retained till his death. He published a volume of "Discourses" (London, 1818), preached to an English congregation in Paris, a series of "Bible Stories for the Young," the "Child's Book of the Soul" (8d ed. 1850), the "Youth's Book of Natural Theology," and other similar works, and edited 6 vols. of the "Annals of the Deaf and Dumb" (Hartford). A discourse on his life, character, and services, by Henry Barnard, was published at Hartford in 1852. His biography, by Heman Humphrey, D.D., was published in New York in 1857.

GALE, I. G., a German astronomer, born in Pabsthausen, Prussian Saxony, in 1812, was for many years director of the observatory in Berlin, and has officiated since 1853 in the same capacity and as professor of astronomy in Breslau. He discovered a comet in the constellation

Virgo (Dec. 2, 1839), in the Dragon (Jan. 25, 1840), and in the Swan (March 6, 1840), and made the first observation of the planet Neptune (Sept. 25, 1846) predicted by Leverrier. He has found from recent estimates, and by comparison with neighboring stars, that the 3d and brightest of Jupiter's satellites is probably of the 5th or 6th magnitude, while the others, which are of various degrees of brightness, are all of the 6th or 7th magnitude; and he supplied his friend Humboldt with a lucid exposition of the photometric arrangement of fixed stars, and with all the calculations respecting the visibility of southern stars in northern latitudes.

GALLEON (Sp. *galeon*), in the middle ages, a large, fast-sailing ship, carrying from 30 to 50 guns; at a later period, among the Spaniards, large armed ships of burden, with 3 masts and 3 or 4 decks, employed especially in transporting treasure from the American colonies.

GALLEY (Fr. *galère*), a long and narrow vessel, low-built, with one deck, propelled by oars and sails, and much used in the Mediterranean until the middle of the 17th century. It was substituted for the ancient trireme under the Byzantine empire, and was adopted by the Venetians and Genoese. It had 2 masts with lateen sails, and those of the largest size were about 166 feet long and 32 broad, with 26 pairs of oars, and carried about 1,000 men, with munitions and provisions for 2 months. The rowers were usually Turkish prisoners or convicts condemned to the oars and chained to the benches on which they sat. This service was deemed one of the severest penalties. The galleys of the knights of Malta were constantly in pursuit of the Mussulmans, and the battle of Lepanto was gained by the galleys of Spain, Venice, and the Holy See over those of Turkey. Galleys were long employed against the Barbary privateers. After the invention of gunpowder the artillery of the galleys usually consisted of 5 cannon in the fore part, 12 swivels on the sides between the oars, and 2 swivels in the stern.—Galleys were formerly used in France, Spain, and the Italian republics, as places of punishment for criminals condemned to hard labor. They were employed as rowers of the galleys, and were called by the English galley slaves. The custom was discontinued in the reign of Louis XIV., when galleys ceased to be used in the navy. The name bagnio is now applied to the prisons which took the place of the galleys.

GALLIA, a S. co. of Ohio, separated from Virginia on the E. by the Ohio river, and drained by Raccoon and Symmes creeks; area, about 420 sq. m.; pop. in 1850, 17,063. It has a rough surface, underlying which are beds of coal and iron. The soil is generally poor except in the vicinity of the Ohio. The productions in 1850 were 377,865 bushels of Indian corn, 62,095 of wheat, 96,831 of oats, 7,908 tons of hay, and 172,131 lbs. of butter. There were 2 grist mills, 1 saw mill, 1 iron foundry, 1 woollen factory, 2 newspaper offices, 22 church-

es, and 2,819 pupils attending public schools. The county was settled by Frenchmen in 1790, whence its name. Capital, Gallipolis.

GALLIC ACID, a product of the decomposition of tannic acid or tannin, obtained in slender, silky needles or crystals. When pure, these are colorless, without odor, and of a sour and astringent taste. They are soluble in 100 parts of cold, or 3 parts of boiling water. Their solution decomposes by exposure to the air. The decomposition of the crystals dried at 212° F. is supposed to be represented by the formula $\text{HO}, \text{C}, \text{H}, \text{O}_2$, though they may perhaps retain an atom of water, in which case it is more correctly $2\text{HO}, \text{C}, \text{HO}_2$. Gallic acid is a useful reagent for detecting the presence of iron in solutions. It does not possess the property of the solution of galls of precipitating gelatine. It is employed in medicine on account of its astringent property, particularly for arresting internal hemorrhages. It is thought to be more readily absorbed than other astringents, and thus to reach more effectually distant parts of the system, while it does not produce, like others, constipation of the bowels. Several methods are in use for obtaining it, either directly from the galls or from the solution of tannic acid first, extracted from them. The powdered galls are made into a paste with water, and exposed for some weeks to the air at a temperature of 70° to 75° F., water being occasionally added to keep the paste moist. The residue, after expressing the paste to free it from the liquid portion, is boiled in pure water, and filtered while hot; the crystals of gallic acid separate as the solution cools. They should be purified by redissolving and boiling with a little animal charcoal or filtering through the same. As the presence of the smallest quantity of sesquioxide of iron will cause the crystals to be colored, the charcoal should be purified, and the filtering paper be washed with dilute hydrochloric acid. Gallic acid is obtained from solution of tannic acid by precipitation with sulphuric acid, the mixture being heated to the boiling point, and allowed to stand a few days.

GALLICAN CHURCH, a name for the Catholic church in France. The exact meaning of the term is not settled; some use it as merely signifying the Catholic church in France, while more commonly it is applied to that church only so far as it holds to certain national privileges, doctrines, and usages. Those who have advocated these distinguishing peculiarities, in opposition to Rome, have therefore generally been called the Gallican party, while their opponents were known as the Roman, papal, or, in modern times, the ultramontane party. There was in the church of France from the beginning a strong feeling of nationalism, the most important manifestation of which is found in the pragmatic sanction of St. Louis (Louis IX.), issued in 1268, which made the paying of taxes to the pope dependent on the consent of the king and the national clergy, and forbade the interference of a foreign power in the affairs of the national

church. The spirit of independence was strengthened by the decrees of the councils of Constance and Basel, which were adopted by France at the assembly of estates at Bourges in 1438, and promulgated in the pragmatic sanction of Charles VII., the fundamental law of the Gallican church. This placed the general council above the pope, forbade the paying of taxes to the pope for appointing bishops and prelates, and abolished the annates after the death of the then living pope. This sanction was repealed by Louis XI. in 1461, but restored by Charles VIII., and by Louis XII. through the edict of 1496. Its most important points were again changed by the concordat concluded in 1516 between Francis I. and Leo. X., which granted most of the demands of the pope, and, notwithstanding the protestations of the parliaments and provincial estates, remained valid until the revolution of 1789. The Gallican church became entirely dependent upon the kings, who often found it to their interest to strengthen the Gallican rather than the Roman tendencies. Thus, some of the decrees of the council of Trent were not received by France, as incompatible with the constitution of the national church, and as too favorable to the influence of the pope. The most important event in the history of Gallicanism is the "Declarations of the French Clergy" (*Declarationes Cleri Gallicani*), which in 1682, by order of Louis XIV., was drawn up by Bossuet, and defined the liberties and doctrines of the Gallican church in the following 4 articles: 1, kings and princes are in temporal matters subject to no spiritual power, and the latter can never absolve subjects from the oath of obedience; 2, the pope is subject to the decisions of an œcumenical council; 3, the power of the pope is moreover limited, as far as France is concerned, by the established prescriptions and usages of the Gallican church; 4, also in matters of faith the decisions of the pope are not infallible when not confirmed by the consent of the whole church. These propositions were proclaimed by a royal ordinance, to which all the instructions of the theological schools were to be conformed; but in Rome they were publicly burned by the common executioner. Louis XIV., in order to restore peace with the head of the church, soon revoked them, but his revocation was not received among the laws of the French state or church, and the articles therefore remained valid, and formed the palladium of the Gallican party in the church. The French revolution overthrew the whole Catholic church in France. Napoleon, as first consul of the republic, reestablished it as a state church by a concordat with Pius VII., in 1801. To the concordat he added, April 8, 1802, organic articles, which enacted that the proclamation of papal decrees depends upon the discretion of the government; that there shall always be an opportunity for an appeal to the council of state against the abuses of ecclesiastical power; and that the teachers in the seminaries shall be always bound by the 4 propo-

sitions of the Gallican clergy. The pope and a majority of the bishops protested against the validity of the organic articles, and a synod convoked in 1811 at Paris refused to declare the church of France independent of the pope. Louis XVIII. concluded, June 11, 1817, a new concordat, by which that of 1801 was abolished, and that of 1516 restored. As, however, the chamber of deputies refused to ratify it, the new concordat never received legal sanction. Although the clergy had no opportunity to declare themselves in synods and councils on the relation of the Gallican church to Rome, it was generally known that a majority were in favor of strengthening the union with Rome, and opposed to defending any thing in the national church which was regarded by Rome as un-Catholic. The remarkable change of ecclesiastical views which has taken place in France since the beginning of the present century is in great part owing to the influence of the works of De Maistre and Bonald. In consequence of some agitation among the people, who were excited against the Jesuits, the government in 1824 demanded of the superiors of the episcopal seminaries, and in 1826 of the bishops, that they should bind themselves to the declarations of 1682. The July revolution of 1830 had but little influence on the inner development of the Gallican church. Louis Philippe made as great concessions to the hierarchy as the origin of his own authority would allow. The bishops whom he appointed were mostly opposed to the Gallican tendencies. An attempt made in 1831 by the abbé Châtel to establish a religious association under the name of the French Catholic church (*église catholique Française*), was at once regarded by the Catholics as being not a movement within but a secession from the national church. The establishment of the republic in 1848 gave to the church a liberty in ecclesiastical and educational affairs which she had not enjoyed for centuries. For the first time within more than 100 years the bishops held provincial and diocesan councils. It appeared that there still existed a difference of views between them concerning the relation of the French church to Rome; but it was no longer the same party division as formerly, the Gallican party of old being found to be almost extinct. All the bishops agreed that it was desirable to strengthen the union between Rome and France, especially in order to give to the national church greater strength to resist the secular rulers. One of the clearest proofs of the spirit now prevailing is the introduction of the Roman instead of the old national liturgies, which took place in one diocese after another, until in 1858 there were only 8 in which the Gallican liturgy was retained. Under Napoleon III. the bishops claim the right to meet without previous authorization in provincial councils; and the government, in order to avoid a conflict, has permitted them to do so without deciding the legal question. The whole French episcopate are at present in the greatest harmony with Rome.—

Some of the most important works on the Gallican church, its history and liberties, are: J. de Maistre, *De l'église Gallicane*; Dupin, *La liberté de l'église Gallicane* (Paris, 1824); Fraysinoux, *Les vrais principes de l'église Gallicane*; and an anonymous *Mémoire sur la situation présente de l'église Gallicane*, addressed to the bishops, and vindicating the Gallican church and its doctrines against the attacks of Count Montalembert.

GALLIENUS, PUBLIUS LICINIUS EGNATIS, a Roman emperor, born A. D. 235, died in 268. He was proclaimed Cæsar by the senate in 253, when his father Valerian was saluted as Augustus. After the latter was defeated and made prisoner in 260 by Sapor, king of the Persians, he governed alone, and saw the empire during his whole reign rent by usurpers, invaded by barbarians, and desolated by the plague. While he abandoned himself to revelry at Rome, nearly 80 of his armies in different parts of the kingdom each elected their general to be emperor, and the military anarchy which succeeded has been called the age of the 80 tyrants. He regarded with indifference the dismemberment of his states, and the dignity of the empire was maintained only in the East, where Odenatus inflicted a defeat upon Sapor. When the legions of Illyria in 268 proclaimed Aureolus emperor, he immediately marched toward Rome to depose Gallienus; but the latter, waking from his apathy, besieged the usurper in Milan, and perished in the siege.

GALLINULE, a wading bird, of the sub-order *grallæ*, family *rallidæ*, and sub-family *gallinulina*; comprising the genera *porphyrio* (Briss.), *tribonyx* (Dubus.) from Australia, *gallinula* (Briss.), and *fulica* (Linn.); the last has been described in the article *Coor*. In the genus *porphyrio* (Briss.), or *porphyryla* (Blyth), the bill is short, thick, and strong, with the culmen much elevated at the base, and dilated on the forehead, with a large frontal plate and compressed sides; nostrils nearly circular; the wings and tail are short and rounded, the 2d, 8d, and 4th quills nearly equal and longest; the tarsi long and slender, with broad transverse scales; the toes very long and free at the base, claws long and somewhat curved. More than a dozen species are described, richly colored, inhabiting warm and temperate regions in pairs or small flocks, on the borders of lakes, rivers, and marshes; they prefer land to water, walk in a dignified manner, run lightly and quickly, and from the length of the toes are able to glide over the surface of floating water plants; their food consists chiefly of fruit, seeds, aquatic roots, and small fish and mollusks; their nest is concealed in the high reeds near the water's edge, made up of dried grasses, and the usual number of eggs is 3 or 4. The only American species is the purple gallinule (*P. martinica*, Linn.), with the head and lower parts fine bluish purple, darker and often nearly black on the abdomen and tibia; the sides and under wing coverts bluish green, and

lower tail coverts white; upper part of body dark green shaded with olive, and tinged with brown on the back and rump; quills and tail brownish black, with green outer edging; bill bright red with yellow tip, frontal plate blue, iris bright carmine, tarsi, toes, and claws yellow. The length to end of tail is about 18 inches, extent of wings 21½, tarsus 2½; weight about 8 oz. It is distributed over the southern states, and is accidental in the middle and northern; it is found also in South America. It runs, swims, dives, and flies well; when travelling far its flight is high, but low and short in its feeding or breeding grounds; it alights with the wings spread upward like the rail; the rapid jerking motions of the tail when alarmed are very remarkable; it sometimes alights on ships 200 or 300 miles from land. Its flesh is not generally held in estimation. It breeds at the south, very early in the year; the nest is built of rushes, 2 or 3 feet from the ground, and is about 10 inches in diameter on the inside; the eggs, from 5 to 7, are of a light grayish yellow, with blackish brown spots; the young, at first nearly black, are fully fledged by the 1st of June.—In the genus *gallinula* (Brisson) the bill is shorter and less stout, the tarsi are stronger, and the toes are margined by a slight membrane throughout their length, though in no way comparable to the pedal lobes in the coot. There are about 12 species in various parts of the world, living on the borders of slow and deep streams edged with reeds; they are more aquatic than the preceding genus, preferring water to land, swimming well and striking the water with the tail; they are excellent fliers and divers, and swim under water by means of their wings; they also walk well, flirting up their tails, and run swiftly among the reeds and through narrow places; they can pass lightly over the leaves of aquatic plants; they eat slugs, worms, insects, grains, &c.; the nest resembles that of *porphyrio*, the number of eggs is 8 to 10, and the young take to the water as soon as hatched. The American species is the Florida gallinule (*G. galeata*, Licht.), very closely resembling the *G. chloropus* (Linn.) of Europe; the principal differences seem to be that in the American bird the frontal plate is quadrate instead of acute, and the toes are longer. The head, neck, and under parts are deep bluish gray, blackish on the head and neck, and lighter on the abdomen; few feathers on the sides edged with white; lower lid, lateral lower tail coverts, edge of wing at shoulder, and outer edge of 1st primary, white; back and wings deep olive, darker on the rump; quills dark brown; tail brownish black; frontal plate and bill bright red, tipped with yellow; bare space on the tibia next to the feathers red; rest of legs yellowish green. The length to end of tail is about 13 inches, extent of wings 22; weight 12 oz. The female is like the male. This species is common in the winter along the rivers, ponds, and lakes, from eastern Florida to Texas, whence it migrates in spring and sum-

mer to the Carolinas, and occasionally even to the middle and northern states; it is also found in South America. It is both nocturnal and diurnal in its habits, often seeking for food on land, walking and nipping insects and grass like the common fowl; it is rarely seen on salt water, but sometimes in the winter visits the banks of bayous in which the water is brackish. The nest is generally a few feet from the water, among the rankest weeds; the eggs, about an inch and a half long, are of a dull dark cream color, with reddish brown and umber spots and dots; when the female leaves her nest she covers the eggs to protect them from crows and other enemies, and both sexes incubate; if not disturbed, they will hatch several broods in a season.

GALLIO, JUNIUS, a brother of the philosopher Seneca, adopted by the rhetorician Junius Gallio, whose name he assumed, died in A. D. 65. He was in 53 and 54 proconsul of Achaia under Claudius, and resided at Corinth, where he refused to listen to charges brought by the Jews against the apostle Paul on "a question of words and names, and of your law" (Acts xviii. 15). From him the name of Gallionism has been applied to indifference to the diversities of religions.

GALLIPOLI (anc. *Callipolis*), a town of Roumelia, European Turkey, 120 m. W. S. W. from Constantinople; pop. about 80,000. It is situated on a peninsula at the N. W. extremity of the Dardanelles, and was formerly well fortified. Its streets are narrow, dirty, and ill built, but its bazaars are large and abundantly supplied with goods. It has many mosques, fountains, Byzantine ruins and monuments, and manufactures of cotton, silk, and fine morocco leather. It has 2 harbors, and frequently receives the imperial fleets. It is the see of a Greek bishop. Gallipoli was formerly of great importance as a centre of the Greek and Italian commerce and as the key of the Dardanelles. The commerce is still considerable in grain, wine, silk, and oil, chiefly in the hands of the Greeks.

GALLIPOLI, a fortified seaport town of Naples, on an island in the gulf of Taranto, 29 m. W. S. W. of Otranto, connected with a suburb on the mainland by a bridge; pop. 8,500. It is well built, with a castle and fine cathedral, and is the great mart for the oil of Apulia, which is collected in extensive tanks excavated in the limestone rock.

GALLITZIN, GOLYZIN, or GALIZIN, a princely Russian family, numerous members of which have distinguished themselves as soldiers, statesmen, or authors. Their origin is traced back to Gedemin, prince of Lithuania, and the ancestor of the Jagiellons. I. MIHAIL commanded, in 1514, a Russian army against the Poles under Prince Ostrogski, was defeated, taken, and held in captivity for 38 years, together with his brother Dmitri, who died in the last year of their detention. Released by King Sigismund II., Mihail was received with distinction by the czar, but retired to a con-

vent, where he died. II. VASIL, defended Novgorod against the first pseudo-Demetrius, but soon followed the example of Basmanoff in espousing the cause of the pretender (1605); stained his hands with the blood of the son and widow of Boris Godunoff, his late master; was rewarded by the usurper, but conspired against him, and contributed to his fall and violent death (see DEMETRIUS); took part also in the conspiracy which overthrew his successor, Basil Shuiski, and was a chief member of the deputation which offered the throne of Moscow to Ladislas, the son of Sigismund III. of Poland. Offended by the conditions of the offer, the Polish king held the Russian envoys in arrest at Kiev, where Vasil died before the termination of the war between the two states. III. VASIL, surnamed the Great, born in 1633, received a classical education, fought against the Turks, Crimean Tartars, and Cossacks, and was made attaman of the latter; was active in bringing about the great reforms of Czar Fedor Alexievitch; was, after the death of that czar, treated with particular distinction by his sister, the princess regent Sophia; concluded in 1686 a favorable treaty with Poland; commanded in a new expedition against the Tartars of Crimea; promoted the ambitious designs of Sophia against her brother Peter the Great, and fell with her. He was tried, condemned, and confined to Yarensk in the government of Vologda, allowed to return to one of his estates on the intercession of other members of the family, but banished again in 1698 to a cold and dreary district in the government of Archangel, where he died. IV. MIHAIL, born about 1675, served in the guards of Peter the Great, and accompanied that monarch on his various campaigns; distinguished himself at the taking of Schlüsselburg; won a victory over the Swedes at Dobry in Lithuania (1706); defeated the reinforcements of Charles XII. under General Lewenhaupt at Liesno; fought in the battle of Pultowa (1709), and a few days after compelled the remnants of the Swedish army to surrender; accompanied the czar on his disastrous expedition to the Pruth (1711); was rewarded for his services with the most flattering honors, and was sent as commander-general to Finland, where he was victorious on land and sea, and remained till the peace of Nystadt (1721). He was made field marshal by Catharine I., the wife and successor of Peter, was also distinguished during the following reign of Peter II., and died in Moscow, Dec. 1730. V. ALEXANDER, son of the preceding, born Nov. 1718, served under Prince Eugene on the Rhine (1738), fought in the 7 years' war, commanded a Russian army on the Dniester in 1768, took Chocim, and died in 1783. VI. DMITRI, born in 1721, was ambassador to the court of Vienna, became by his will the founder of a magnificent hospital in Moscow, and died in 1793. VII. DMITRI, born in 1738, was sent in 1763 as ambassador to France, where he became acquainted with the most eminent men of the age; married Amalia, daughter of Count Schmet-

tan; went in 1773 as ambassador to the Hague; retired after the conquest of Holland by the French to Brunswick, wrote on natural sciences, and died in 1803. Among his works are a *Description de la Tauride* (1778), and a *Traité de la minéralogie* (1792). VIII. AMALIA, wife of the preceding, born in Berlin, Aug. 28, 1748, made the acquaintance of Prince Dmitri at Aix la Chapelle, was married to him, but afterward lived in separation from her husband, first in the vicinity of the Hague, and subsequently at Münster in Westphalia, where she became the centre of a circle of pietistic writers, being herself remarkable for literary accomplishments as well as personal attractions. She contributed not only to the peculiar religious development of her son Demetrius (see GALLITZIN, DEMETRIUS AUGUSTINE), but also to the conversion of Count Frederic Stolberg to Catholicism. Goethe was among her visitors, and Hemsterhuys addressed to her, under the name of Diotima, his *Lettre sur l'athéisme* (1785). She died Aug. 24, 1806. IX. SERGHEI fought against the Turks, under Potemkin, against the Poles in 1794, and against the Austrians in Galicia in 1809, commanding the troops which assisted the Poles to drive back the archduke Ferdinand, when he died. X. EMANUEL, born in Paris in 1804, studied in that city, entered the Russian army, distinguished himself at the taking of Varna, returned to France, travelled subsequently through Russia and other countries, wrote, translated, and edited in French a number of works on Russia and its literature, especially descriptions of travels, and died at Paris in Feb. 1858.

GALLITZIN, DEMETRIUS AUGUSTINE, a Russian nobleman, who exercised the functions of a missionary priest in the United States, born at the Hague, Dec. 22, 1770, died in Loretto, Penn., May 6, 1840. His father while Russian ambassador in Paris had gained the friendship and embraced the principles of Voltaire and Diderot; his mother, the countess of Schmettau, had similar inclinations; and the young Demetrius, while educated in all secular learning and accomplishments, was strictly debarred from a knowledge of religion. In his 17th year, however, he became a member of the Roman Catholic church, which his mother had joined a short time before. His father designed him for the army, and in 1792 he was aide-de-camp to Gen. Van Lilien, who commanded the Austrian forces in Brabant during the first campaign against the French. After the death of the emperor Leopold and the assassination of the king of Sweden, Austria and Prussia dismissed all foreigners from their armies; and his own country being at peace, Demetrius resolved to travel in America. He was accompanied on the voyage by a young German missionary, the Rev. Mr. Brosius, who improved the influence which his position as tutor gave him over the young prince's mind to turn his thoughts toward the priesthood. Soon after landing, in 1792, Demetrius entered the theological seminary recently founded by the Sulpicians in Baltimore,

and on March 18, 1795, he was ordained priest by Bishop Carroll, being the second Roman Catholic upon whom that order was conferred in the United States. He also joined the society of Sulpicians, but subsequently, finding his relations with the latter inconsistent with the life of a missionary, he unwillingly broke them off. His first pastoral charge was at Cone-wango, Penn., whence he officiated at various towns in the states of Pennsylvania, Maryland, and Virginia, until in 1799 he selected a bleak uncultivated spot, high up on the Alleghany mountains in Cambria co., Penn., about 250 m. from Philadelphia, as the site of a proposed Catholic colony. He purchased a large tract of land, which he divided into small farms and sold at a nominal price, or oftener gave away, to emigrants, erected saw and grist mills, and having laid the foundation of a town, named it Loretto. To meet the heavy debt which he thus incurred he relied upon his patrimony; but on the death of his father in 1803, the Russian government, in consequence of the son's change of religion, refused to allow him to succeed to the estate, and he was consequently involved for a time in great embarrassments. Some assistance from his relatives, however, from the king of Holland, one of his early friends, and from the Russian ambassador at Washington, relieved him, and he expended on his settlement about \$150,000. His life was peculiarly austere and laborious. His plain log cabin was always open to the poor and strangers, his dress was of the simplest homespun, and he concealed his rank under the assumed name of "Father Smith." There were at that time few Catholic priests or churches in Pennsylvania, and Father Gallitzin added to the care of his flock at Loretto incessant journeys over a wild and extensive region. He found time to compose several controversial works which were extensively read; his "Defence of Catholic Principles," "Letter to a Protestant Friend," and an "Appeal to the Protestant Public," are still often reprinted. He was several times proposed for the episcopacy, but would never accept that honor. At his death he left a flourishing community of 6,000 persons at Loretto. His name has since been given to a village there, and a monument was erected to his memory before the church in 1848.—ELIZABETH, Princess Gallitzin, cousin of the preceding, born in 1796, died in St. Michael's, La., Dec. 8, 1843. She abjured the Greek faith, joined the society of the sacred heart in Rome, and in 1840 was sent to America as visitatrix of the order. She founded an establishment in New York, and another in the far west at Potawatamie village.

GALLON, an old English measure of capacity, subdivided into 4 quarts. Formerly there were gallons of different capacities, one for wine, another for ale or beer, and a third for grain and dry goods. The wine gallon, called also the standard gallon, contained 231 cubic inches, the ale gallon 282 cubic inches, and the

corn gallon 268.6 cubic inches. In 1825 the imperial gallon was established by the British parliament, the capacity of which was 10 lbs. avoirdupois of distilled water, that weighed 252.458 grains to the cubic inch, thus making its contents 277.274 cubic inches. The gallon of the United States is the standard or Winchester wine gallon of 2.31 cubic inches, and contains 8.3388822 avoirdupois lbs. or 58372.1754 troy grains of distilled water at 39.83 F., the barometer being at 30 inches. The gallon of the state of New York is of the capacity of 8 pounds of pure water at its maximum density, or 221.184 cubic inches.

GALLOWAY, JOSEPH, an American loyalist, born in Maryland about 1730, died in England in Sept. 1803. He was educated for the bar, and in early life removed to Philadelphia, where he attained considerable eminence in his profession. In 1764 he became a member of the Pennsylvania assembly, and joined his friend Dr. Franklin in advocating the adoption of a royal government for the colony instead of the proprietary form then in use, which involved him in a controversy with John Dickinson. Subsequently he became speaker of the assembly, and in 1774 a delegate to the first congress. In this body he took a prominent part, and proposed to settle the difficulties between the colonies and the mother country by vesting the government in a president-general of the colonies, to be appointed by the king, and a council to be chosen by the several colonial assemblies; the British parliament to have the power of revising the acts of the latter body, which in its turn was to have a negative on British statutes relating to the colonies. The plan, though advocated by a few members, was rejected by congress; and the author, who had never been in favor of a political separation from Great Britain, although he had warmly urged the redress of the grievances which the colonists suffered, abandoned the whigs after the question of independence had begun to be agitated, and thenceforth was known as a zealous tory. He remained with the British army in Philadelphia and New Jersey until 1778, when he went with his daughter to England, where he passed the remainder of his life. Being summoned in 1779 before a committee of the house of commons to testify on American affairs, he animadverted severely on the course of Gen. Howe and other British officers. A new edition of this "Examination" was published in Philadelphia in 1855 by the "Council of the Seventy-Six Society." Galloway's estate, estimated to be worth £40,000, was confiscated upon his departure for Europe; but a large portion was subsequently recovered by his daughter. His literary remains comprise a "Speech in answer to John Dickinson" (8vo., London and Philadelphia, 1764); "Candid Examination of the Mutual Claims of Great Britain and the Colonies" (8vo., New York, 1775); "Letters to a Nobleman" (8vo., 1779); "Reply to Sir William Howe" (1780), &c. In the latter part of his life

he became interested in the scriptural prophesies, and wrote on the subject.

GALLS, or GALL NUTS, hard woody excrescences, in size from that of a pea to that of a nutmeg, formed by an insect on the twigs of the dwarf oak, *quercus infectoria*, in Syria and Asia Minor. (See GALL INSECTS.) They are brought to the United States principally from Smyrna and Trieste, and, being produced near Aleppo, are often called Aleppo galls. They are also obtained from Calcutta, to which place they are supposed to have been carried from Persia. Those are the best which are gathered when of good size, but before the insect by which they are produced has eaten its way out. They are known as black or blue galls, and possess in a higher degree the dark coloring property and the medicinal virtues of the article than the larger ones, from which the insect has escaped, and which are known as white galls from their lighter dingy color. About the season of gathering the galls they are carefully examined upon the trees, in order to collect them in their best condition. They are then of a dark bluish or lead color without, and internally whitish or brownish, hard and rough, with a knotted surface. They are solid, but easily broken, and form when ground a light yellowish gray powder. In the centre is a spot or cavity, caused by the presence of the larva or insect. Their taste is bitter and disagreeable, but they are without odor. They are powerfully astringent, and have been used in medicine since the time of Hippocrates; but excepting as a gargle in the form of infusion or decoction, or for external application mixed with some ointment, they are now little employed. Their chief value is in their soluble portions, producing black dyes when mixed with solutions of sulphate of iron. The portion that is soluble is taken up by 40 parts of boiling water. Ether takes up $\frac{1}{3}$, alcohol $\frac{1}{5}$ of the galls. The solution serves to detect the presence of iron in other solutions. Galls are used as a source of tannin or tannic acid, the principal ingredient in their composition, as appears by the following analysis of Guibourt: tannic acid, 65; gallic acid, 2; ellagic and luteo-gallic acids, 2; brown extractive substance, 2.5; gum, 2.5; starch, 2; sugar, 1.3; chlorophyl and volatile oil, 0.7; woody fibre, 10.5; water, 11.15; total, 100. It is questionable whether the gallic, ellagic, and luteo-gallic acids exist in the substance of galls, or are produced by the action of the oxygen of the air upon the tannic acid, this being easily thus converted into other acid compounds. The tannin is separated by treating the powdered galls with ether mixed with about one-tenth part of water protected from the air. The greater part of the tannin thus extracted separates from the ether by standing, and is obtained in a concentrated aqueous solution. The aqueous solution of galls possesses the property of precipitating gelatine from its solutions, by the tannic acid it contains.

GALLUP, JOSEPH ADAM, an American physician and author, born in Stonington, Conn.,

March 30, 1769, died in Woodstock, Vt., Oct. 12, 1849. He had not the advantages of a collegiate training, although he received a very thorough education, and in 1798 he was graduated as bachelor in medicine at Dartmouth college. He practised medicine a few years in Hartland and Bethel, Windsor co., Vt., whence he removed to Woodstock in Jan. 1800. His first writings appeared in 1802 in the "Vermont Gazette," published at Windsor, and attracted early attention. For 8 years commencing in 1820 he was president of and a professor in the institution at Castleton, Vt., then called the Castleton medical academy, and was also for several years a lecturer in the medical department of the university of Vermont. He subsequently established the medical institution at Woodstock, called at the outset the clinical school of medicine, and delivered his first course of lectures there in the spring of 1827. This school afterward became the Vermont medical college, and was incorporated in 1835. In 1815 he published "Sketches of Epidemic Diseases in the State of Vermont," to which are added "Remarks on Pulmonary Consumption," which was republished in England. He published in 1822 his "Pathological Reflections on the Supertonic State of Disease," beside other pamphlets, and in 1839 his more considerable work in 2 vols., entitled "Outlines of the Institutes of Medicine, founded on the Philosophy of the Human Economy in Health and Disease."

GALT, JOHN, a Scottish author, born in Irvine, Ayrshire, May 2, 1779, died in Greenock, April 11, 1839. After spending some years in mercantile life he began to study law at Lincoln's Inn, London, but in 1809 set out on a tour of nearly 3 years in southern Europe and the Mediterranean, publishing the results of his observations on his return in two books of travels. He sailed from Gibraltar to Malta with Lord Byron and Mr. Hobhouse, and in the Levant he schemed to introduce British goods into the continent by way of Turkey in defiance of the Berlin and Milan decrees. He had in 1803-'4 contributed to the "Scots' Magazine" portions of an ambitious composition in octosyllabic verse. He next produced a volume of dramatic pieces, which Scott called "the worst tragedies ever seen," and which was followed by lives of Benjamin West and Cardinal Wolsey, a tragedy entitled the "Appeal," acted in Edinburgh for a few nights, and "The Earthquake," a novel in 3 volumes. These works, written in the intervals of various commercial undertakings, made no impression upon the public, but his "Ayrshire Legatees," which appeared in successive numbers of "Blackwood's Magazine" in 1820-'21, unexpectedly turned the popular tide in his favor. Within the next 3 years appeared the "Annals of the Parish," generally esteemed his best work, written 10 or 12 years before, but then rejected by the publishers, the "Provost," which he himself preferred, the "Steamboat," "Sir Andrew Wyllie," the "Gathering of the West," the "En-

tail," "Ringhan Gilhaize," the "Spaewife," "Rothelan," and the "Last of the Lairds," all novels of Scottish life, and all successful. The character of Leddy Grippy in the "Entail" was a special favorite with Byron. In 1826 he visited Canada as the agent of the Canada company, a large landholding corporation; he founded in the forest the town of Guelph, but a difference with his employers having cast him adrift again, he returned to England in 1829, and shortly afterward took advantage of the insolvent debtors' act. He returned to his literary labors, and during the remainder of his life produced a number of novels and a variety of miscellanies, including a "Life of Lord Byron," the "Autobiography of John Galt" (2 vols., 1833), and "Literary Life and Miscellanies of John Galt" (8 vols., 1834). His novel "Laurie Todd" (1830), relating some of his experiences in the new world, is considered in his best vein. It was followed by "Southenham," "Bogle Corbet," "Stanley Buxton," the "Member," the "Radical," "Eben Erskine," and the "Lost Child." He died after 14 strokes of paralysis, having dictated compositions long after losing the use of every limb. His works are of very unequal merit, but are usually marked by an original quaintness and vigor and by defects of taste. The facility with which he wrote is attested by the fact that notwithstanding many years of his life were surrendered to business pursuits he published 44 works, of which 24 were novels, many in 3 vols.

GALVANI, ALOISIO, or LUIGI, an Italian physician, the discoverer of that branch of electricity which bears his name, born in Bologna, Sept. 9, 1737, died there, Dec. 4, 1798. Being of a devotional turn of mind in his youth, he was educated for the priesthood; but his tastes subsequently inclined toward the natural sciences, and abandoning theology he took the degree of M.D. at the university of Bologna in 1762. Soon after he was appointed medical lecturer at the institute of Bologna, to the "Memoirs" of which he became a frequent contributor, and increased his reputation by treatises on the urinary organs, and the organs of hearing in birds. In 1786 accident led him to his great discovery in physical science. (See ANIMAL ELECTRICITY.) During the French occupation of Italy he was deprived of his offices, and his pecuniary resources and health began to decline. The death of his wife also afflicted him greatly. Under the weight of these misfortunes he sank rapidly, and although his offices were subsequently restored to him, he died before resuming their duties.

GALVANISM. See ANIMAL ELECTRICITY, and ELECTRO-DYNAMICS.

GALVANIZED IRON. Sheets of iron superficially coated with zinc are said to be galvanized, though the methods usually practised of applying this coating do not require the use of the galvanic battery. By Mallet's process the sheets are first cleansed by immersion in a warm bath of equal parts of sulphuric or hy-

drochloric acid and water, followed by hammering and scrubbing with emery and sand. They are then placed in a preparing bath of a saturated solution of hydrochlorate of zinc and sulphate of ammonia; and from this they are removed to a metallic bath composed of 202 parts by weight of mercury and 1.292 parts of zinc. To every ton weight of the amalgam one pound of potassium, or better of sodium, is added. At the temperature of 680° F. the compound fuses, and the zinc is deposited upon the iron sheets; the iron at the same time is attacked so strongly, that in a few seconds a plate an eighth of an inch thick would be dissolved, if allowed to remain. Small articles are most advantageously treated after the strength of the mixture has been somewhat spent upon larger ones. Another method is to plunge the cleansed sheets of iron into a bath of melted zinc covered with sal ammoniac, and stir them about for some time. Undiluted commercial acids are also used for cleaning the surface of the iron, in which case some bits of zinc are immediately added, which dissolves and is directly precipitated, forming a film upon the iron. When coated the articles may be applied to use, or they may be made still more effectually to resist the action of oxidizing agents by next dipping them in a bath of melted tin. This metal then forms the exterior coat, and adheres much more firmly than if it had been applied directly to the iron.—The first attempt to protect iron for practical purposes from rusting, by means of the application of an unoxidizable metal, was made by Prof. John W. Revere, M.D., of New York. On March 17, 1829, he brought before the lyceum of natural history of New York the results of experiments upon which he had been occupied the 2 preceding years, and exhibited iron spikes which after being driven into a block of wood had been left since June 14, 1827, in sea water; also an iron plate, secured to wood with iron nails, which had been similarly exposed. These did not present the slightest appearance of corrosion. Dr. Revere at first looked only to the preservation of the iron fastenings used in copper sheathing; but his experiments satisfied him that the sheathing itself might be of iron sheets protected from all danger of rusting by electrochemical agency. This invention was patented in the United States and England, and either according to his original method, or by the same slightly modified, has been ever since extensively applied in practice.

GALVESTON, a S. E. co. of Texas, bordering on the gulf of Mexico and on Galveston bay, and including a long narrow island of the same name separated from the mainland by West bay; area, 680 sq. m., of which 406 sq. m. are land.; pop. in 1858, 6,922, of whom 1,208 were slaves. Its surface is generally level and its soil sandy and productive. The most valuable land is on Galveston island. In 1850 the productions were 5,780 bushels of Indian corn, and 4,705 of sweet potatoes.—GALVESTON, the capital of the county, a port of entry, and

the principal city of Texas, is situated at the N. E. extremity of Galveston island, and at the mouth of the bay of the same name, the entrance to which is by a narrow channel between the city and the S. W. point of the long peninsula of Bolivar; lat. $29^{\circ} 18' 11''$ N., long. $94^{\circ} 48' 48''$ W.; pop. in 1850, 4,177; in 1859 estimated at 10,000, about 1,000 of whom were negroes. The island is about 28 m. long and from $1\frac{1}{2}$ to $8\frac{1}{2}$ m. wide, intersected by many small bayous, diversified by several fresh water ponds, and bordered through its whole length by a smooth hard beach, which forms a pleasant drive and promenade. The bay is an irregular indentation, branching out into various arms, and receiving Trinity and San Jacinto rivers and Buffalo bayou. It extends 85 m. N. from the city to the mouth of Trinity river, and has a breadth of from 12 to 18 m. The harbor is the best in the state, and has 12 feet of water over the bar at low tide. There are several ship-building and repairing yards, good wharves, and large store-houses adjoining them. Nearly all the foreign trade of the state is transacted here, and the entrances and clearances from and to foreign ports during the year ending June 23, 1858, were as follows:

Vessels.	Entered.		Cleared.	
	Number.	Tonnage.	Number.	Tonnage.
American	14	4,231	81	14,041
Foreign	9	4,635	7	8,476
Total	23	8,866	88	17,517

The value of imports during the same period was \$71,881, and that of exports, \$2,428,465. The registered tonnage of the port was 3,589, and the enrolled and licensed 5,490; total 9,080. A large proportion of the trade, however, is carried on coastwise, and the total number of entrances during the year 1856 was 3,594, of which 1,065 were steamers. The principal business is shipping cotton, of which the annual receipts from the interior for exportation amount now (1859) to 800,000 or 400,000 bales. A large commerce is carried on with Brazoria by means of a canal. The Galveston, Houston, and Henderson railroad, now in course of construction, is in operation from Virginia point, on the mainland opposite Galveston, to Houston, a distance of $42\frac{1}{2}$ m.; and a railroad bridge, nearly 2 m. long, from Galveston to Virginia point, across the bay, was to have been completed by Sept. 1859. Regular lines of steamers ply between this port and New York, New Orleans, the S. W. towns of Texas, &c. The city has several foundries and machine shops, cotton presses, hotels, &c., and in 1858 contained 8 or 10 churches, 2 of which, the Episcopal church and the Roman Catholic cathedral, are costly brick buildings in the Gothic style, a female seminary, an academy, a convent of Ursuline nuns, a number of common schools, a bank (the only one in the state), many elegant stores and private houses, and several newspaper offices. The Roman Catholic uni-

versity of St. Mary is a large brick structure at the E. end of the city; it was founded in 1854, incorporated with power to confer degrees in 1856, and is under the charge of the order of Minor Conventuals.—The island of Galveston was occupied by the notorious pirate Lafitte in 1817, and continued to be his headquarters until his settlement was broken up by Lieut. Kearney, commander of the U. S. brig Enterprise, in 1821. The growth of the city dates from 1837.

GALWAY, a maritime county of Ireland, in the province of Connaught, bounded N. by Mayo and Roscommon, E. by Roscommon, King's county, and Tipperary, S. by Clare and Galway bay, and W. by the Atlantic ocean; length from E. to W., 92 m.; breadth from N. to S., 57 m.; area, 2,447 sq. m., of which less than one half is arable, the rest being mountain, bog, or water; pop. diminished from 414,684 in 1841 to 298,564 in 1857, and in 1859 probably not much above 270,000. The western part of the county is rugged and barren. Here are the celebrated district of Connemara and Lough Corrib, one of the largest of the Irish lakes. The E. division is in general level and fertile. Agriculture is in a very backward state. The principal crops raised are oats, barley, and wheat, and the total extent of land under crops in 1855 was 238,696 acres. Grazing is much followed, and the cattle and sheep are greatly esteemed. Limestone and marble are the chief minerals, and a very beautiful species of the latter is obtained near Oughterard, in the neighborhood of which town there is also a lead mine. The coast fisheries would be valuable if properly prosecuted. The principal fishing districts are Galway and Clifden. Galway has some manufactures, the most important of which are woollen hosiery, coarse linens, and friezes for home consumption. Celtic cromlechs and Anglo-Norman castles are frequently to be met with in this county. It returns 4 members to parliament. Its chief towns are Galway, Tuam, Loughrea, and Gort.—GALWAY, an ancient seaport town, capital of the above county, is situated on the N. side of Galway bay, $126\frac{1}{2}$ m. by rail from Dublin; lat. $53^{\circ} 15' 12''$ N., long. $9^{\circ} 8' 30''$ W.; pop. in 1851, 24,697. In the old town the streets are narrow, irregular, and dirty, but in the modern part they are in general spacious, handsome, and cleanly. The chief public edifices are the Queen's college, a beautiful building in the Elizabethan style, the collegiate church of St. Nicholas, which is in the decorated English style, and the Franciscan convent, a large and stately structure. There are several Roman Catholic chapels, monasteries, and nunneries, some Presbyterian and Methodist meeting houses, and two handsome court houses. Galway has few manufactures, but it has 2 breweries, 2 distilleries, a paper mill, a foundry, a tannery, and several flour mills in the town and neighborhood. It was formerly the principal emporium of Ireland, and the commerce was

considerable, especially with Spain. Latterly, however, it has fallen off greatly. The principal exports are corn, flour, kelp, marble, wool, and provisions. The chief imports are timber, wine, salt, coal, hemp, tallow, and iron. The entrances in 1856 were 88 vessels, tonnage 8,394, and the clearances 61 vessels, tonnage 6,185. It has a floating dock, which has an area of 5 acres, and admits vessels of 14 feet draught. On Mutton island, in front of the harbor, is a lighthouse 33 feet above high water. Galway returns 3 members to parliament.—In 1858 a regular steam service with New York, stopping at St. John's, Newfoundland, was commenced by Mr. John Orrel Lever, to whom, in 1859, Lord Derby's government gave a postal contract.

GAMA, VASCO DA, the discoverer of the route to India round the cape of Good Hope, born in Lines, a small Portuguese seaport, it is not known at what date, died in Cochín, India, Dec. 24, 1525. Bartholomew Dias, a Portuguese explorer, having visited the cape which he called *Cabo Tormentoso*, or stormy cape, brought back such interesting accounts of his discoveries that the Portuguese sovereign Emanuel, following the policy of his predecessor John II., determined to urge discovery beyond the point where Dias left it, and if possible to reach by sea the countries of the Indies. Accordingly an expedition was placed under the command of Vasco da Gama, a gentleman of the king's household, and a skilful and experienced mariner. The fleet consisted of the San Gabriel, flag ship of 120 tons, the San Rafael of about 100 tons, a caravel of 50 tons, and a store ship, with a total force of 160 men. The king presented Gama with the flag of the military order of Christ (a white cross within a red), also the journal of Covilham the navigator, who had 10 years before gone to India by way of the Red sea, and with letters to all known potentates, and to the mysterious Prester John. On July 8, 1497, Gama's expedition departed from Lisbon for the Cape Verd islands, whence it set sail on Aug. 8 southward along the African coast. For 3 months the voyagers pursued their way, harassed, as an early English narrator says, with torments of wind and rain. On Nov. 7 they put into a bay called St. Helena, near the cape, where they found the natives "lyttle men, ill favored in the face and of color blacke, and when they did speake it was in such manner as though they did alwayes sigh." Departing on the 16th, they encountered a succession of tempests such as had gained for the southern promontory of Africa the name of the cape of Storms. The courage of Gama's companions failed, and they besought him to put back, which he not only refused to do, but put the ringleaders of the movement in irons, and held on his course into the stormy sea. When they were beating about off the promontory, Gama fancied that he saw the spirit of the cape. Camoëns has sung this incident as a fact, while moderns, less poetical, say that the apparition could have been nothing more than that peculiar cloud whose sudden envelopment of the

cape is the forerunner of a storm. On Wednesday, Nov. 20, they doubled the cape of Storms, or rather, as Emanuel himself had named it ere the expedition set out, the cape of Good Hope. Proceeding along the coast, they touched at various points, among others at Natal. Further N. they discovered Mozambique, and came upon a country which exhibited a high stage of commercial advancement, the inhabitants having regularly built ports, with mosques. The natives were Mohammedans, carrying on a trade in pearls, rubies, silver, linen, and spices with Arabia and India. Gama took with him a pilot from this place. On April 1 the explorers discovered the island of Açoutado, which Gama so named from a flogging he gave to his pilot there; and on the 7th the island of Mombassa, where the people who inhabited it were bravely appparelled in silken stuffs and jewelry. As these men tried to cut his cable, Gama seized a boat containing 17 of them, and carried them off to Melinda, 8° S. of the equator, where the king of the place entered into the most friendly relations with the Portuguese, and gave them a pilot to conduct them across the Indian gulf. Melinda was described as a regularly built city, with wide streets, and houses of more than one story. The Melindese pilot is reported to have been acquainted with the astrolabe, compass, and quadrant. Under his guidance the voyagers steered 750 leagues across the open sea. In 23 days they arrived off the Malabar coast, and on May 20, 1498, they reached Calicut, the object of their search. Their mission was thus accomplished, and a new route to the East established. Gama's relations with the ruler of Calicut, who was called the Samoudri-rajah (abbreviated to Zamorin), were not of a cordial nature; and therefore, leaving the Indian coast on Oct. 15, Gama returned to Lisbon, calling at Melinda on the way to take on board an ambassador to Emanuel's court, and arriving in the Tagus, Sept. 1499, after an absence of 2 years and 2 months. He brought back only 55 men and one ship, a caravel which he had chartered at Cape Verd. The San Rafael had been lost on the coast of Africa, the store ship burned according to Gama's instructions, the San Gabriel condemned at Cape Verd, and Nicolao Coelho had slipped away with the remaining vessel, in order to be the first to tell the great news in Portugal. The king received Gama splendidly, and permitted him to bear the high-sounding title of "lord of the conquest of Ethiopia, Arabia, Persia, and India." Emanuel immediately fitted out a second fleet of 13 ships, with 1,200 men, under the command of Pedro Alvarez Cabral, to establish trading posts; but failing in its ends, another fleet of 20 ships was placed under command of Gama. This expedition, which was warlike in its character, sailed early in 1502. On reaching the Indian seas Gama made a treaty with the kings of Sofala and Quiloa, the latter agreeing to pay tribute to Portugal. Determined now to strike terror into the hostile kings of the Indian coast, he seized a large ship containing

800 male and female pilgrims of the highest rank of various nationalities on their way to Mecca, and killed them all, excepting 20 children, whom he saved to bring up in the Christian faith, as an atonement for one of the Portuguese who had apostatized to Mohammedanism. This sanguinary affair at once opened to him the port of Cananore, whence he sailed to Calicut, seizing on the way 50 of the natives. Here he demanded the right to trade, with immediate reparation for past indignities, and, not receiving it promptly, he hung his 50 prisoners at the yard arm and burned the town. Thence he proceeded to Cochin, where he entered into friendly relations with the king, and presented him a golden crown from the king of Portugal. The Calicut Zamorin, however, made war on Cochin for this alliance with the strangers. Gama, leaving 5 ships to cruise on the coast, returned home with 18 ships, having a battle on the way with the Calicut fleet, which he utterly routed. On his return the king created him admiral of the Indian ocean and count of Vidigueria. For the next 21 years Gama lived in retirement, till 1524, when, the Portuguese dominion having largely expanded in the East, John III. appointed him viceroy of the Indies. He proceeded to his seat of government, but died in the succeeding year at Cochin. In person Gama was short and stout, with a florid complexion. The salient points of his character were intrepidity, perseverance, and fertility in expedient, but he was sudden and violent in anger. In 1558 his body was brought to Portugal and interred with honor. Barras has published an account of his voyages, and Camoëns celebrates them in his "Lusiad." Dr. Pertz, the director of the royal library in Berlin, has announced his discovery of documents which tend to show that the route to the East *via* the cape was known 200 years previous to Gama.

GAMALIEL, a Pharisee, doctor of the law, member of the sanhedrim, and teacher of Saul, who was afterward the apostle Paul, died about A. D. 88. In the Talmud he is surnamed Hazaken, "the Elder," to distinguish him from his grandson and is represented as grandson of Hillel, the renowned teacher of the Mishna. He held a seat, and probably the presidency, in the sanhedrim during the reigns of Tiberius, Caligula, and Claudius. When Peter and the other apostles were brought before the council in Jerusalem, after being miraculously released from prison (Acts v.), he recommended to "let them alone, for if this counsel or this work be of men, it will come to nought; but if it be of God, ye cannot overthrow it; lest haply ye be found even to fight against God." The respect with which his opinions are always quoted by the rabbins is irreconcilable with a tradition that he was converted to Christianity by Peter and John.

GAMBIA, a British colony of W. Africa, occupying both banks and some islands of the river whence it derives its name; pop. in 1851, 5,693, of whom 191 were whites. In 1858-59

there were 462 births, 871 deaths, and 110 marriages. The chief settlements are Bathurst, Fort James, and Fort George. Bathurst and Fort James are situated in St. Mary's island near the mouth of the Gambia; Fort George on McCarthy's island, about 180 m. from the sea. The climate is generally considered unhealthy. In summer the heat is excessive, the thermometer frequently rising to 106° and 108° in the shade. The soil is rich and alluvial, and liable to periodical inundation. The principal exports are beeswax, ground nuts, and hides, and the imports cotton goods, tobacco, amber, rum, &c. In 1855 there were in Gambia 7 schools, attended by 715 male and 634 female pupils. The revenue of the colony was £15,853, and the expenditures £15,210. There were entered 217 vessels of 32,619 tons, and cleared 215 vessels of 32,242 tons. The imports amounted to £126,454, and the exports to £215,804.

GAMBIA, a large river of W. Africa, rising in the interior of the continent, and after a course of more than 100 miles, discharging itself into the Atlantic ocean at Bathurst, in lat. 13° 30' N., long. 16° 40' W. It is 9 m. broad at its mouth, and is navigable for vessels of 800 tons burden for 90 m. inland.

GAMBIER, a post village of Pleasant township, Knox co., Ohio, founded in 1826 on a tract of land belonging to Kenyon college; pop. in 1850, about 280. The college, which is an Episcopal institution, was established under the auspices of Bishop Chase in 1826, by funds which he had collected in England. It is richly endowed, and comprises 4 buildings, the principal of which is an imposing stone edifice in the Gothic style, 190 feet long and 4 stories high. There are 5 professors, 50 students, a number of pupils in the preparatory department, and 8,720 volumes in the library. The commencement is on the first Wednesday in August. Connected with the college is the theological seminary of Ohio, founded in 1828, and having a president, 3 professors, and a library of 4,500 volumes. The village occupies a beautiful site on a high ridge nearly surrounded by Vernon river. It contained in 1850 an academy, a few stores, and the offices of 2 or 3 religious periodicals. It was named after Lord Gambier, a benefactor of the college, the latter being named after Lord Kenyon.

GAMBIER, JAMES, baron, a British admiral, born in the Bahama islands, Oct. 18, 1756, died at Iver, near Uxbridge, April 19, 1838. He was of a French Protestant family, expatriated by the revocation of the edict of Nantes. Early entering the naval service, he obtained in 1778 the rank of post captain, and as commander of the frigate Raleigh was engaged in repelling the French attempt upon Jersey in 1781, and afterward in the reduction of Charleston, S. C. In 1793 he was appointed to the command of the Defence, of 74 guns, under Earl Howe, and in the engagement with the French fleet under Villaret de Joyeuse (June 1, 1793) his ship was the first to break through

the enemy's line. Advanced to the rank of rear-admiral in 1795, and of vice-admiral in 1799, he became third in command of the channel fleet in 1801, and in the following year was intrusted with the government and defence of Newfoundland. In 1807 he commanded the fleet sent to Copenhagen with troops under Lord Cathcart to demand the surrender of the Danish navy. The bombardment of the city continued 3 days, when Admiral Gambier took possession of 19 sail of the line, 23 frigates and sloops, and 25 gun boats, together with the stores in the arsenal. He was rewarded with the dignity of baron, and with the offer of a pension, which he declined. In 1808 he was appointed to the command of the channel fleet, drew up a code of signals and the general disciplinary instructions for the navy, and in April, 1809, attacked the French squadron in the Aix roads and burned 5 of the ships. Lord Cochrane had command of the British fire ships (catamarans), and in consequence of a disagreement between him and Lord Gambier, the latter requested a court-martial, by which he was honorably acquitted. In 1814 he was appointed at the head of the commissioners to conclude a peace with the United States, and the treaty was signed at Ghent on Dec. 24. He afterward lived in retirement, received the grand cross of the order of the bath in 1815, and was made admiral of the fleet on the accession of William IV. He was distinguished for benevolence and piety, and as an officer exerted himself to promote religious observances among the seamen under his command.

GAMBOGE, or **CAMBOGE**, a gum resin of Siam and Cochin China, and produced also in Ceylon. The tree from which it is obtained is the *hoeradendron cambogioides* of Dr. Graham of Edinburgh. The gum was first carried to Europe by the Dutch in 1608. It is imported into the United States only from Canton and Calcutta. The manner of collecting it in Siam is to catch in leaves or cocoanut shells the yellow milky juice which exudes from the fractured shoots and leaves of the tree, and, transferring this to earthen vessels, leave it to thicken. It is poured when semi-fluid into the hollow joints of the bamboo, and thus receives the cylindrical form and the shape of pipes or hollow cylinders by contraction in solidifying. It is also made into lumps or cakes of several pounds weight; these are commonly more or less mixed with bits of wood and other impurities. Farinaceous matters are also employed to adulterate it, their presence being detected by the green color communicated to the decoction by adding iodine. The inferior kinds are known in commerce as coarse gamboge. Those of finer quality are brittle, with conchoidal fracture, of reddish orange color in the mass, but bright yellow in powder, or when rubbed with water. It is without odor, and its taste, very slight at first, is soon followed by an acrid sensation in the throat. Its emulsion with much water affords films, which are good microscopic

objects for the observation of active molecules. It is wholly taken up by alkaline solutions and by strong acids. Its resinous portion is dissolved by sulphuric ether; the whole by the successive action of ether and water. The following analyses are given by Dr. Christison of the different qualities of gamboge:

Constituents.	Siam Gamboge.			Ceylon Gamboge.
	Pipe.	Cake or lump.	Coarse.	
Resin	72.5	64.7	48.3	71.8
Soluble gum	22.7	20.8	15.3	19.9
Woody fibre	trace.	5.8	12.8	5.7
Fecula	5.6	14.5	...
Moisture	4.8	4.1	8.8	8.2
Total	100.0	100.0	100.0	100.0

The resinous portion is obtained by evaporating the ethereal tincture. It has a deep orange color, and gives a yellow tint to 10,000 times its weight of alcohol. It is entirely insoluble in water. Johnston named it gambogic acid, and gave its composition $C_{10}H_{12}O_6$. This is said to be an active purgative in the dose of 5 grains, without the drastic and nauseating character of the gum resin. Gamboge is employed as a water color, and also as a medicine. In large doses it is an acrid poison, a single drachm having produced death. It is best used in combination with other and milder cathartics, and is then found an excellent remedy for obstinate constipation. It is also employed in the treatment of apoplexy and dropsy.

GAME LAWS, statutes which declare what birds and beasts are to be considered game, and impose penalties on those who unlawfully kill or destroy them. The game laws of England had their origin in the ancient forest laws, under which the killing one of the king's deer was equally penal with murdering one of his subjects. From the Norman conquest to the present day game has constantly been a subject of legislation in England. In 1889 the possession of property was made a specific qualification for the privilege of killing game, and it was enacted that "no manner of artificer, laborer, nor any other layman who hath not lands and tenements to the value of 40 shillings by the year, nor any priest nor other clerk if he be not advanced to the value of 10 pounds by the year," shall keep hunting dogs, or use other methods of killing game, upon pain of one year's imprisonment. In 1605 the qualification to kill game was increased to £40 a year in land and £200 in personal property. In 1670 the qualification was limited to persons who had a freehold estate of £100 per annum, or a leasehold for 99 years of £150 annual value. Persons who had not these qualifications were not allowed to have or keep game dogs. In 1785 an act was passed requiring persons qualified to kill game to take out a certificate to that effect. The property qualification was abolished in 1881, since which time the certificate itself, which costs £3 18s. 6d., gives a qualification. It must be taken out annually, and expires in

July. The sportsman must show it when demanded by collectors of taxes, gamekeepers, landlords, occupiers, and lessees, and if he refuses is liable to a penalty of £20. Uncertificated persons caught sporting are liable to a penalty of £5 for each offence, though the owner or occupier of enclosed grounds has a right to kill hares on his own grounds without taking out a game certificate. There are many restrictions upon the right which a certificate gives to kill game. It must not be killed on Sunday nor on Christmas, nor at the season when the pursuit of each kind of game is prohibited. The law is very severe against poachers or unauthorized persons who destroy game by night. For killing game or rabbits on any land at night, or for trespassing upon such land with instruments for taking or killing game, the penalty is 8 months at hard labor in the house of correction; and if at the expiration of the term the poacher cannot give security for good behavior for a year, he may be further imprisoned for 6 months. A third offence is punishable with transportation for 7 years, or 2 years' imprisonment. It is felony to unlawfully hunt, kill, or wound any deer kept in any enclosed land, and the punishment is transportation for 7 years or imprisonment for 2 years. Lords of manors are authorized to appoint gamekeepers to preserve or kill game within the manors. Gamekeepers are authorized to arrest poachers, and to seize all dogs, nets, and other implements used for killing game by uncertificated persons. The sale of game in England is subject to very strict regulations. A dealer in game must obtain an annual license in July. Innkeepers, victuallers, retail beer-sellers, coachmen, guards, and common carriers are prohibited from dealing in game. The administration of the English game laws being entirely in the hands of the class interested in preserving the game, they are very rigidly enforced.—In the United States laws have been enacted by several of the states to protect game from pursuit during certain seasons in order to prevent its entire destruction. But apart from these restrictions, any person who chooses is at liberty to kill or capture as best he can any wild animal, bird, or fish, anywhere in the United States, subject only to the usual laws against trespassing on the grounds of other persons.

GAMING, the playing together of two or more persons at some game, whereby one shall lose and the other win money or other property staked upon the issue. The game may be one of chance, as that of faro, or a game with dice, or one of skill only, as chess, or of skill and chance together, as whist or backgammon. There is nothing immoral in playing for mere amusement; but if money be staked, it becomes easily, and perhaps necessarily, a sport carried on for the sake of the money, in a greater or less degree, and then most moralists have agreed that it deserves reprobation. When this is carried to an extreme degree, and important sums are played for, it is obviously wrong, and deem-

ed so to be universally. But the common law never interfered with gaming, by any kind of prohibition or restraint, so long as there was no fraud. If there was fraud, it operated here as it does elsewhere in law; it avoided all contracts, and money paid in fraud could be recovered back, because no title passed to the payee. And if one cheated at gaming, as by false cards, dice, or other implements, or indeed in any way, he might be indicted as a cheat at common law. Both in England and in the various states of the Union, statutes have been passed for the prohibition or restraining of gaming, or, as it is commonly called, gambling. Here, all gambling, that is, all playing for money, is prohibited, and therefore it is held that one cannot recover back money lost at play, because the playing itself is illegal; and it makes no difference whether the playing was honest or cheating. But a loser may recover his money from a stakeholder, by demanding it from him before he pays it over to the winner. It has been held in Indiana that winning any sum of money, however small, at cards, is an indictable offence. But it has been said in New York, that playing to see who shall pay for the use of the implements, as a billiard table, is not gambling.

GAMING HOUSES, houses kept for the purpose of enabling persons to gamble therein. These are said to be nuisances, and indictable as such at common law; but the keeping of them is prohibited and punishable by statute in most of the United States.

GAMMELL, WILLIAM, an American author, born in Medfield, Mass., in 1812. He is the son of the late Rev. William Gammell, who was settled in Newport, R. I. He was graduated at Brown university in 1831, and soon afterward was appointed a tutor in the university; in 1835 he was chosen assistant professor of rhetoric, and in 1836 professor of rhetoric, in the place of the late Prof. W. G. Goddard, who then resigned. He continued to perform the duties of that office till 1850, when he was transferred to the professorship of history and political economy. Prof. Gammell has published various orations and discourses on literary and historical subjects; also numerous articles in reviews and magazines, especially in the "Christian Review," of which, for several years, he was one of the editors. He has written a life of Roger Williams, and one of Governor Samuel Ward, for Sparks's "American Biography." He is also the author of a "History of American Baptist Missions," which was written at the request of the board of the American Baptist missionary union; a work which forms a most valuable contribution to the history of Christian missions. The writings of Prof. Gammell are marked by an elegance of diction and an earnest moral and religious tone.

GAMUT, in music, the scale on which the notes are placed in their several orders. Its invention is ascribed to the monk Guido Aretino, who commenced his scale with the note represented by the Greek letter Γ (gamma), corre-

sponding to the English G. Before his time musical scales commenced on A, one degree higher. (See ARISTINO, GUNDO.)

GANDO, a city and kingdom in Africa, lying on both sides of the principal branch of the Niger. The city is the residence of the sultan, and lies in a narrow valley surrounded by hilly chains. It is intersected from N. to S. by the broad and shallow bed of a torrent, the borders of which are covered with luxuriant vegetation, and it is adorned with a variety of trees, among which the banana is prominent. The onion of Gando is superior in size and quality to any produced in the neighboring districts. Though a central place and favorably situated for commerce, at the time of Dr. Barth's visit (May, 1853) it was extremely dull, and its commerce was insignificant, a fact which was explained by the anarchical state of the provinces around. The inhabitants prepare cotton cloth of excellent quality, but their dyeing is much inferior to that which distinguishes the manufactures of Nupe and Kano.—The kingdom of Gando consists of several rich provinces, comprising the western half of Kebbi, Mauri or Arewa, Zaberma, Dendina, a great part of Gurma, a small portion of Borgu or Barba, a large portion of Yoruba, Yaura, and Nupe or Nyfi. Much of the territory is well inhabited, and presents a luxuriant vegetation, embracing the yam, the date, and the banana. The inhabitants are of the Foola race, and most of them Mohammedans. The latest rulers of the kingdom have been Aba Allahi, Mohammed Wani, and Khalilu, who, when visited by Dr. Barth in 1858, was in the 18th year of his reign. Khalilu lives in almost monastic seclusion, leaving the administration in the hands of one of his brothers, and the provinces have consequently been plunged into anarchy and mutual hostilities.

GANGES, the principal river of Hindostan, rising on the S. slope of the Himalaya mountains, and falling into the bay of Bengal. Its remotest feeder is the Bhagirathi, which issues from a wall of snow, supposed to be 800 feet thick, in the territory of Gurhwal, between the mountains St. Patrick, St. George, and the Pyramid, at an elevation of 13,000 feet above the sea. Thence it flows N. W. to Bhairogathi, where it is joined by the Jahnvi, a considerably larger stream than itself, and bends westward and then S. W. At Sookhee, in lat. 30° 59' N., long. 78° 45' E., it breaks through the Himalaya proper at an elevation of 7,608 feet, its average descent from its source having been 70 feet per mile, though to Bhairogathi it is 255 feet. Its general course is then S. W., S., and S. E., to Deoprag or Devaprayaga, in lat. 30° 8', long. 78° 39', where, 120 m. from its source, it receives the large river Aluknunda, and first takes the name of Ganges. Thence it flows W. and S. W., receiving on the right the Sooswa, and on the left the Nyar, to Hurdwar, 47 m. Its direction is now nearly S. for about 180 m.; thence S. E., receiving about midway the Ramgunga on the left and the Kallee Nuddee on the

right, 368 m. to Allahabad, where it is joined by the Jumna on the right. Down to this point it is full of shoals and rapids, and in many places fordable, though navigable by small boats from Hurdwar, and by passenger steamers from Ghurmuckteesur, 398 m. above Allahabad. From the latter place its course is generally E. for about 500 m. to Sikrigalee, and thence the main stream flows S. E. to its mouth. At Manjhee, 270 m. below Allahabad, it receives the Gogra; 18 m. below this, the Sone; 20 m. further down the Gunduck, and 160 m. further the Coosy. At Seebgunge, 95 m. from the mouth of the Coosy, and 568 from Allahabad, it sends off to the S. a large branch called the Bhagruttee, and 70 m. lower down another called the Jellinghee, which two offsets unite and form the Hoogly, considered by the Brahmins the true channel of the sacred river. The main stream below the divergence of the two feeders of the Hoogly is known as the Podda or Ganges. It throws off several branches, among which are the Konaie, the principal outlet of the Bramapootra, and the Kirtynassa, and 65 m. below the latter it unites with the Meghna, which carries its remaining waters to the sea, its mouth being in lat. 23° 52' N., long. 89° 45' E. The total length of the Ganges, reckoning from the source of the Bhagirathi in Gurhwal, is 1,514 m. to the mouth of the Hoogly, or 1,557 to the mouth of the Meghna. Of the vast number of channels which form its delta only the Meghna and its branch the Chundna are navigable by large craft at all seasons to the main stream. The waters of the Ganges generally rise from the end of May to September, when the lower parts of Bengal, for a width of 100 m., are completely inundated. The rise at Calcutta is about 7 feet, and at Benares and Allahabad 80 or 45. The general width of the river, according to Capt. Prinsep, is "very unequal, but may be reckoned to average a mile in the dry season on its whole course through the plains, and two miles in the freshes." The average discharge of water, according to Rennell, is in the dry season 80,000 cubic feet per second, and in the wet season 405,000 cubic feet. The Ganges brings down great quantities of earthy matter, and its course at intervals is obstructed by extensive shoals. Large tracts of land are sometimes swept away by the current in a single season, and remarkable changes are thus frequently made in the channel. The Ganges is universally regarded by the Hindoos as a sacred stream, and its waters are carried great distances to be employed in ceremonial ablutions; they are also used to swear by in courts of justice. There are particular places, however, which are held more holy than the rest, and these are resorted to by great numbers of pilgrims. The country watered by this river is one of the finest in the world, abounding in every kind of vegetable product suited to that region, and adorned with beautiful scenery. The principal cities and towns on its banks are Furruckabad, Cawnpore, Allahabad, Benares,

Ghazeepeer, Patna, Bahar, and Moorshedabad. Calcutta and Hoogly are on the Hoogly.—The Ganges canal, designed both for the irrigation of the Doab and for purposes of navigation, now in course of construction, will be when completed one of the grandest works of the kind in the world. The main line extends from Hurdwar to Allyghur, where it branches, one division leading to Cawnpore and the other to Humeerpoor, and 3 lesser channels diverge to Futtehgur, Coel, and Bolundshahur. The whole work when completed will be 810 m. long, 525 m. of which were opened in 1854.

GANGLION, in anatomy, a small rounded or elongated nervous mass, of a reddish gray color, situated in the course of the nerves. There are 2 kinds of nervous ganglia, one forming part of the cranial system of nerves, the other part of the sympathetic system; the first kind are situated near the origins of many of the cranial and of all the vertebral nerves, and on the posterior or sensory root of the latter; the second are generally placed along the sides of the anterior surface of the spinal column, from the head to the coccyx, the 2 great semilunar and cardiac ganglia coming near the median line. They are composed of 2 substances, one white like the medullary substance of the brain, the other reddish gray, somewhat resembling the cerebral cortical substance; the internal medullary filaments are the continuation of the nerve upon which the ganglion is situated. The nervous system of ganglia is considered by some as a series of more or less independent centres, giving off nerves to the organs of nutrition or communicating branches to the cerebro-spinal system; according to others, these ganglia and their associated nerves form a special system with numerous ramifications, the sympathetic system presiding over the involuntary contractions of the heart and digestive apparatus, and all the processes concerned in secretion, nutrition, and exhalation, and in disease conveying different sympathetic phenomena from one part of the organism to another. Strictly speaking, all the nervous centres in the highest vertebrates may be called ganglia; even the hemispheres of the human brain may properly be styled cerebral ganglia. The principal ganglia of the head are the ophthalmic, which sends branches to the iris and the vascular apparatus of the eyeball; the otic, intimately connected with the organ of hearing; Meckel's or the spheno-palatine, ministering to the senses of smell and taste; the submaxillary, whose branches proceed almost entirely to the gland of that name; the Gasserian, of the 5th pair of nerves; and those near the roots of the pneumogastric and glossopharyngeal. In the neck are the superior, middle, and inferior ganglia of the sympathetic, and the origins of the cardiac plexus which supplies the heart; in the chest, the 12 thoracic ganglia on each side, from which originate the splanchnic nerves which go to form the semilunar ganglia or solar plexus; in the abdomen, the latter sends

branches which accompany all the divisions of the aorta; there are beside these the lumbar and sacral ganglia on each side of the spine, distributing their branches to the organs in the pelvis. The so called lymphatic ganglia are glandular, and not nervous masses. In the invertebrata ganglia are the highest forms of nervous centres, and occur either isolated or connected together by single or double longitudinal cords; they perform the functions both of the cerebral and spinal centres of the higher animals.—In surgery, a ganglion is a small indolent fluctuating tumor, developed in the course of the tendons, containing a semi-fluid secretion inclosed in a cyst generally communicating with the tendinous sheath. It is a dropsy of the synovial sheath, caused by friction, some wrench or tension of the tendon, or the sequence of some rheumatic or gouty disease; the light of a candle may be seen through it. The most common situation is about the wrist and fingers, though it may occur in the course of any tendon. When there is no inflammation, the best treatment is to puncture the tumor by the subcutaneous method, in order that the contained fluid may escape into the surrounding areolar tissue and be absorbed; pressure and cold applications should then be applied. If this fail, stimulating liniments and even blisters may be tried, to induce absorption. When unconnected with a tendinous sheath, the tumor may be dissected out, punctured like an abscess, or transixed with a seton; the subsequent thickness may be removed by the vapor or steam bath and douche; any rheumatic taint requires to be corrected by appropriate remedies. A popular way of treating these tumors is to rupture them by a strong and sudden blow; those on the back of the wrist and hand may thus be scattered without danger.

GANGRENE, the loss of life in any of the soft parts of the body, without extinction of the vital powers in the rest of the organism. The term *ephacelus* has been applied to the condition in which gangrene may terminate, the utter and irrecoverable death of a part, while in some stages of gangrene the circulation may not be completely arrested, the sensibility of the nerves not entirely gone, and recovery of the local loss of action not impossible. The death of the bony tissue is called *necrosis*. When gangrene is the consequence of violent inflammation or of the obstructed return of venous blood, the affected parts are gorged with fluid, constituting humid gangrene; while dry gangrene generally arises from a deficient supply of arterial blood or from constitutional causes, accompanied by very slight or by no inflammation, the mortified part becoming dry and hard; the gangrenous portion in the former case is called a slough, in the latter an eschar. The local predisposing causes are congestion and deficient circulation; the constitutional are weakness from disease, old age, or misery. The exciting causes are mechanical and chemical injuries, especially gun-shot, lacer-

sted, and poisoned wounds; insufficient supply of arterial or obstructed return of venous blood, as in the gangrene from ossified arteries in the first case and that from heart disease and varicose veins in the second; and injury or division of nerves. The areolar tissue is most subject to gangrene; after this come tendons and ligaments, denuded bone, the skin, and the muscles, in the order of enumeration. Gangrene spreads slowly or rapidly, according to the accompanying inflammation or the energy of the vital processes. When inflammation is about to end in gangrene, the redness becomes livid, with diminution of pain and sensibility, though the swelling may be increased; the parts become soft and cold, and emit an odor of decomposition; the livid color, when the disease is spreading, is gradually lost in the surrounding skin, but when the dead portion is to be cast off, a bright red line separates the healthy from the gangrenous tissue, called the "line of demarcation;" in a healthy person there may be high accompanying fever, but in a debilitated constitution the symptoms will be those of prostration and typhoid. The indications of treatment are to diminish the inflammation by general and local depletion; to support the strength by tonics and stimulants, when the gangrene is extensive or the system debilitated; to quiet restlessness and nervous irritability by opium; and to facilitate the separation of the dead parts by warm and stimulating applications, and by incisions to permit the free escape of fluids whose absorption might propagate the disease to internal vital organs. Amputation of a limb is sometimes the only way of arresting the spread of gangrene. Surgery often has occasion to produce gangrene as a remedial measure, in the removal of tumors and diseased growths; hemorrhoidal swellings, nasal and uterine polypi, erectile tumors, cancerous growths, &c., are effectually and safely removed by cutting off their supply of blood by ligature of the principal vessels. Gangrene is always a dangerous symptom, especially in very young or very old persons, and in weakened constitutions; and when terminating favorably, it may leave behind it tedious suppurations, fistulous ulcers, and various deformities. Hospital gangrene, or sloughing phagedæna, a putrid disease caused by crowding sick and wounded men into ill-ventilated and dirty rooms, is one of the most terrible accompaniments of war, often destroying more than the bullet and the sword; and the army surgeon generally finds his best directed efforts set at defiance by the force of the surrounding and insurmountable obstacles; the principles of treatment are the same as in ordinary gangrene.

GANGUE (Germ. *Gang*, a vein), the matrix or veinstone of ores. These are always included in some stony matter, which forms the principal portion of the veins or beds which are worked for the sake of their metalliferous contents. Quartz is the most common veinstone, and has been called the mother of ores. Calca-

reous spar is also a frequent predominant material of veins. Sulphate of barytes or heavy spar, and fluor spar, are also often found as gangues.

GANJAM, a district of the Madras presidency, British India, bounded N. and N. W. by Orissa, S. E. by the bay of Bengal, and S. W. by the district of Vizagapatam; area, 5,728 sq. m.; pop. 926,930. The coast is bold, rocky, and destitute of large harbors, though coasting vessels can anchor within the mouths of some of the rivers. The most important streams are the Chicacole, Callingapatam, and Rasikoila, all of which are dry during part of the year. A range of hills runs through the district from S. W. to N. E., in many places approaching close to the shore, in others receding a few miles, and in the N. part leaving between it and the coast a wide sandy plain, in which, partly in this district, but mostly in Orissa, lies the lake of Chilka, 42 m. long, 15 m. broad, and only 6 feet deep. The climate, during the hot and part of the rainy season, is unhealthy. The soil in general is productive, and the staples are rice, maize, sugar cane, millet, pulse, oil seeds, wax, lac, guma, dye stuffs, arrow root, and a little cotton for domestic use. Valuable ornamental woods are found. The only manufactures are coarse cottons and muslins, which have greatly declined since the general introduction of European fabrics. Ganjam is one of the 5 districts formerly called the Northern Circars, of which the French obtained possession in 1758, and passed into British hands only after a violent contest between the British and French, which was decided by Olive in 1759. The principal towns are Ganjam, Chicacole, Russelkondah, and Guntoor, the last of which acquired some notoriety about 1840-'45, in connection with the Meriah sacrifices practised by the Khoonds of the frontier. Young human victims, in great numbers, were immolated to propitiate a divinity presiding over the fertility of the earth, and so wedded were this barbarous tribe to their horrible rites that the sacrifices were only abolished by vigorous military operations.

GANNAL, JEAN NICOLAS, a French chemist, born in Saar-Louis, July 28, 1791, died in Paris, Jan. 1852. After being employed at a drug shop, he was in 1808 attached as an apothecary to the medical department of the French army. In 1816 he became the chemical assistant of Thénard in his lectures at the Sorbonne. Industrial pursuits and useful inventions afterward engaged his attention, in which he was very successful. He invented a new kind of chimney, the first elastic rollers for the printing press, the refining of borax, a new method for melting and hardening tallow employed in making candles, &c. In 1827 he received the Montyon prize from the institute for his system of chloric inhalation for catarrh. He is best known, however, by his process for embalming bodies, the first public experiments in which were made in 1838, and for which he received the same

prize. It consists in injecting a solution of sulphate of aluminum into the carotid artery.

GANNET, a web-footed bird, of the family *Sulidae* and genus *Sula* (Briss.). The genus is characterized by a bill longer than the head, strong, straight, and broad at the base; the sides compressed and grooved toward the tip, which is slightly curved, with the lateral margins obliquely and unequally serrated; the nostrils basal, linear, in a lateral groove, and almost invisible; the wings long and pointed, the 1st and 2d quills longest; the tail long and graduated; the tarsi short and stout, rounded in front and keeled behind; the toes long, all 4 connected by a full membrane; the claws moderate and rather flat, the middle one serrated, and the hind one rudimentary; beneath the lower mandible is a naked sac, capable of moderate distention. There are about 10 species described, in various parts of the world, of which 2 are natives of the western hemisphere, the booby (*S. fiber*, Linn.), treated under its own title, and the gannet, or solan goose (*S. bassana*, Briss.). The gannets are usually found in immense numbers on desert and rocky islands near the mainland, migrating southward in small parties on the approach of cold weather; they sometimes float lightly on the sea, but are generally seen on the wing; their flight is powerful, rapid, buoyant, and long sustained; their food consists of fishes which swim near the surface, upon which they dart headlong from a considerable height, making a great splash, and sometimes remaining under water a minute or two; they swallow the fish head foremost, and their gullet is so expansible as to take in the largest herring. The common gannet (*S. bassana*, Briss.) has a close dense plumage, of a general whitish color, buff yellow on the head and hind neck, and primaries brownish black; the bill is pale bluish gray; bare space about the eye and on the neck blackish blue; iris white. The length to end of tail is 40 inches, to end of wings 38, the extent of wings about 6 feet, and the bill 4 inches; the weight is 7 lbs. The female is like the male, but smaller. The young are brown and white above, and grayish white below. This species breeds in great numbers on the rocky islands near the coast of Labrador, and after the breeding season, in May and June, is found all along the Atlantic states to the gulf of Mexico; it is entirely maritime, and never seen inland unless forced in by violent gales. The flight, when travelling, is low, performed by 30 or 40 flaps of the wings, and then by sailing for an equal distance with extended neck; the walk is exceedingly slow and awkward. The nest is a hole in the earth surrounded by weeds and sticks matted together for a height of 10 to 20 inches, and only a single pure white egg, about 8 inches long, is laid in it; the young are hatched in about a month; the males assist in incubation. They congregate on the same rock in vast numbers, and are quarrelsome during incubation, being fond of stealing from each other the materials for the nests, which are sometimes brought a distance of 30

miles. A young gannet, with its large head, closed eyes, thin neck, small wings, large abdomen, naked skin, and bluish black color, is a most uncouth and disagreeable object. When shot at or wounded, gannets disgorge their food like vultures. They have very few enemies among birds or beasts; the eggs and young are sometimes devoured by the larger gulls. According to Audubon, the feathers on the lower parts are very convex externally, giving the appearance of light shell work.

GANNETT, EZRA STILES, D.D., an American clergyman, born in Cambridge, Mass., May 4, 1801. He studied at Phillips academy, Andover, entered Harvard college in 1816, and was graduated in 1820; studied the three following years in the divinity school at Cambridge; received ordination as colleague with William Ellery Channing, June 30, 1824; and, with the interruption of 2 years' absence in Europe on account of ill health, he has continued pastor of the Federal street church in Boston for more than a third of a century. Beside publishing many occasional discourses at the request of his audience, and editing the "Monthly Miscellany" from 1844 to 1849, he was associated with Dr. A. Lamson in the care of the "Christian Examiner," the principal periodical of the Unitarian denomination in the United States. Dr. Gannett has been among the foremost in the religious and benevolent enterprises of his denomination, in which he holds an eminent rank for his devotion to pastoral duty, his fervid eloquence, and his conservative theological tendencies.

GANOIDS (Gr. *γανος*, splendor), in Müller's classification, an order of fishes having either enamelled scales, bony plates, or a naked skin; fins generally, but not always, covered anteriorly by spiny plates (*fulcra*); the internal skeleton sometimes osseous, as in the gar pike, or partly cartilaginous, as in the sturgeons; the vertebral column occasionally extending to the end of the upper caudal lobe; nasal apertures double; gills free and lying in an operculated cavity, with or without an opercular gill, a pseudo-branchia, and blowing holes; the arterial trunk always with numerous valves; no decussation of the optic nerves, and the ventral fins abdominal; there is always an air bladder, and a duct communicating with the œsophagus; the eggs are conveyed from the abdominal cavity by tubes; like the shark family, they have a thymus gland, and often a spiral valvular fold in the intestine. Müller divides the ganoids into 4 families: 1, containing the American gar fish; 2, the *polypterus* of Africa; 3, the *amia*, or mud fish of America; and 4, the sturgeons. These will be described under the 1st, 3d, and 4th titles respectively. Prof. Agassiz is inclined to elevate the ganoids from an order to a class, separate from ordinary bony fishes and superior to them in organization, though inferior to the selachians (sharks and rays); he makes them the 3d class of the branch vertebrata, with the 3 orders of coelacanthas, acipenseroids (sturgeons), and sau-

roids (gar fish), with 8 additional doubtful orders of siluroids, plectognaths (*balistes*, *ostracion*, and porcupine fishes), and lophobranchs (*hippocampus*, pipe fish, and *pegasus*).—The remainder of this article will be devoted to the consideration of fossil ganoids, and to the interesting questions connected with their structure and geological distribution. Ganoid fossil scales, whether angular, rhomboidal, or many-sided, are imbricated like the slates of a roof, and formed of an outer plate of enamel, an inner porcelanic layer, and an intermediate reticulated structure analogous to the diploë between the tables of the human skull. The fin rays of the ganoids are bare enamelled bones, each consisting of a plate of enamel on each side and a lamina of bone between them; the necessary flexibility of such rays is secured by joints which extend through the rigid enamel, leaving the central bony plate undivided, on the principle of the half-sawed moulding which the carpenter wishes to bend at an angle or around some curved surface. The dermal or external skeleton of the ganoids is so remarkably developed, that in many instances it has served to determine the forms of genera and species in the old red sandstone and carboniferous strata, every other portion having perished, as their internal skeletons were either very slight or entirely cartilaginous; enamelled plates represent the head, enamelled imbricated scales indicate the form and proportions of the body, and enamelled rays show the position and outline of the fins. The instances of great development of the outer skeleton in higher animals are few, being limited principally to the armadillo and pangolin among mammals, the tortoises and crocodiles among reptiles, and the gar pikes and sturgeons among fishes. The earliest fishes, those of the silurian epoch, seem to have been all placoids; in the following age, that of the old red sandstone, the ganoids appeared in great numbers, and with the placoids formed the entire class of fishes for unknown millions of years, that is, through the old red sandstone, carboniferous, permian, triassic, and oolitic periods, down to the cretaceous epoch, when ordinary bony fishes were brought into existence—the age of these 2 orders corresponding nearly to the reign of the ferns, palms, coniferous trees, and their allies among plants. When the bony fishes became the prevailing type, the other orders diminished in proportion, so that at the present time the gar pikes and the sturgeons are the chief representatives of the old powerful and numerous ganoids. In the human family we see similar instances of nations reaching their culminating point, and then disappearing or lapsing into barbarism; the Aztecs of Central America and the Copts of Egypt are the remnants of the great races which built the mounds of the Mississippi valley and the Egyptian temples and pyramids. In the words of Hugh Miller: "But in the rivers of these very countries, in the *polypterus* of the Nile, or the *lepidosteus* of the Mississippi, we are presented with the few surviving fragments

of a dynasty compared with which that of Egypt or Central America occupied but an exceedingly small portion of either space or time. The dynasty of the ganoids was at one time coextensive with every river, lake, and sea, and endured during the unreckoned eons which extended from the times of the lower old red sandstone until those of the chalk." Among ganoids are found some of the strangest ichthyic forms, presenting a structure and placoid affinities no longer seen in nature; these gigantic and strange fishes were of the first rank in their class, and, being then the only existing representatives of the vertebrates, exhibited characters belonging to the higher class of reptiles, of which they were the prophetic types. These reptilian fishes attained their greatest number and largest size during the carboniferous period, and were remarkable both for their formidable offensive weapons, and their strong defensive armor. This remote age was as fully characterized by bloodshed and destruction of animal life as any since the creation of man; indeed no animal ever had more powerful teeth than the ganoid *rheodus* of the coal fields, sharper and 4 times as large as the hugest living crocodile can boast of; the dorsal and caudal spines of some of the contemporary placoids far exceeded in size and destructive properties those of any living shark or ray; where such weapons were employed, defensive armor to resist them was kindly bestowed by the Creator—hence the enamelled scales of the ganoids. The ganoid teeth and scales bore the same relation to each other that the heavy maces, battle axes, and two-handed swords did to the steel armor of the days of chivalry; the sharp teeth of modern carnivorous fishes are suited for the soft and generally defenceless bodies of the ctenoids and cycloids, as the keen scymitar and slender rapier are best suited for the defensive coverings of modern warfare. In the lepidoid or acanth family, confined chiefly to the old red sandstone and carboniferous strata, the teeth are small, brush-like, and in several rows, or obtuse and in a single row; the scales are flat, rhomboidal, parallel to and wholly covering the body; all those occurring in strata earlier than the jurassic have the tail heterocercal or with the spine prolonged into its upper lobe; it has no representative among living fishes. Among the most interesting genera are *dipterus*, in which *D. macrolepidotus* of the old red sandstone resembles a fish carved in ivory, crusted with enamel, and thickly dotted with minute puncturings; with circular scales, thickly enamelled fin rays, strong angular pectorals, scale-protected ventrals like the hind fins of the *ichthyosaurus*, and a long dorsal and anal, the former consisting of 2 portions. *Osteolepis*, also British devonian, has 2 anals alternating with 2 dorsals, large and rounded pectorals, small ventrals, large mouth, and scales of moderate size. Among the genera most numerous in the coal measures are *palæoniscus*, a small, handsome, and well-proportioned fish, with moderate-sized fins and scales, a sin-

gle dorsal opposite the space between the ventrals and anal, and all with small rays at their margins—about 80 species in North America and northern and central Europe; *eurynotus*, a flattened and bream-shaped species, with large dorsal, ventrals, pectorals, and head; and *anthodes*, with lengthened body, very small scales, dorsal opposite anal, no ventrals, large pectorals, and very wide mouth, in proportions resembling the conger eel or ling. Among those most numerous in the jurassic age are *tetragonolepis*, with a broad flattened body, rapidly decreasing to the tail, rounded head, moderate fins, and pointed teeth—about 20 species in Europe; *lepidotus*, with body shaped like a carp's, large rhomboidal scales, and caudal fin almost square—about 80 species; and *pholidophorus*, resembling the herring, but with rhomboidal scales, homocercal or equal-lobed tail, and small teeth—more than 30 species.—In the family of cephalaspids, which contains the extreme acanth forms for a long time not recognized as fishes by paleontologists, the body and head are covered with a few non-imbricated plates or shields; the heterocercal tail, covered with imbricated scales, has no true caudal fin; and in place of pectorals are 2 long bony appendages or stiletts; the dorsal cord like that of the sturgeons; they belong to the old red sandstone formation, and were short-lived in comparison with some other ganoids. The genus *pterichthys* (winged fish), discovered by Hugh Miller in the Cromarty sandstone, first appears at the base of the old red sandstone, and disappears with its upper beds; one of the most recent species, *P. major*, is the largest; it is as strange a form among fishes as the *plesiosaurus* and *pterodactyle* among reptiles; in his work on "Fossil Fishes," Prof. Agassiz says: "It is impossible to find any thing more eccentric in the whole creation than this genus." Hugh Miller describes it, when seen from the under surface, as resembling the "human figure, with the arms expanded as in the act of swimming, and the legs transformed, as in the ordinary figures of the mermaid, into a tapering tail." There is no separation between the head and trunk, and the whole animal is in a complete armor of solid bone; the strong helmet of the head is perforated in front by 2 circular holes for the eyes, the body above and below protected by a curiously plated cuirass, and the tail sheathed in a flexible mail of bony scales; the plate-covered arms are articulated by a complicated joint to the lower part of the head; the flat abdomen and ribbed and groined arch of the back add to the strength of the armature without increasing the weight—the creature resembling a "subaqueous boat, mounted on two oars and a scull;" and this strange fish is a characteristic organism of the old red sandstone. The genus *coccosteus* has not the pectoral appendages of the preceding animal, and the head and anterior part only of the trunk are covered with a bony helmet and cuirass, the caudal portion being naked; it has one dorsal

and one anal fin; the mouth is furnished with small, equal, conical teeth. The most remarkable peculiarity in this fish, unique among vertebrated animals as far as known, is that the jaws possessed both the usual vertical motion, and also a horizontal movement as in crustaceans, indicated by the 2 sets of teeth, one on the upper edge of the jaw and the other on the line of the symphysis, the latter of which, if brought into action at all, could only be so by the lateral movement of the jaws. The jaws of *coccosteus* are also interesting, as presenting the most ancient internal bone which has displayed its structure under the microscope. The jaw of this ancient fish shows the Haversian canals, the lacunæ and osseous cells, as in the bones of man at the present time; showing the extension of the great creative plan through the most distant ages, and by a fair inference to the beginning of vertebrate existence. The genus *cephalaspis*, or buckler-head, had a thin triangular body, and crescent-shaped head covered with a singular shield-like plate, with lateral prolongations extending along the sides; body covered by vertical rows of scales; no ventrals nor pectorals, and 2 dorsals. It lived at the same time with large placoids, armed with dorsal spines (of which the spines only remain), and with a gigantic lobster-like crustacean more than 4 feet long; it belongs to the middle portion of the old red sandstone.—The family of saurroids, of which the gar pike is one of the few living representatives, had pointed conical teeth alternating with small brush-like ones; the skeleton bony; the scales flat, rhomboidal, and completely covering the body; those living before the jurassic age had unequal-lobed tails, while the homocercal genera flourished at a more recent period. The genus *megalicthys* was a formidable fish of large size; the scales of the body and the plates of the head had such a brilliant enamelled surface, "that they may still be occasionally seen in the shale of a coal pit, catching the rays of the sun, and reflecting them across the landscape, as is often done by bits of highly glazed earthenware or glass." The genus *diplopterus* was of smaller size, with an elongated tapering body, flat head, rounded muzzle, 2 dorsals, 2 anals, and the caudal fin truncated almost vertically, the lobes coming off laterally from a prolongation of the vertebral column; their scales were of great brilliancy, and must have flashed brightly through the woods of the coal period, as they leaped into the air in sport or in pursuit of prey. The genus *pygopterus* had the fins greatly developed, and a heterocercal tail; *aspidorhynchus* had a much elongated body, homocercal tail, the upper jaw prolonged into a beak and extending beyond the lower, the scales large; the former belongs to the coal and magnesian limestone formations, and the latter to the jurassic.—The coelacanth family is characterized by having all the fin rays and bones hollow, a peculiarity not found in other ganoids; and all the fin rays are stiff, articulated only at their bases, and sup-

ported on interapophyseal small bones; they occur in all the ages from the lower devonian to the chalk formations, most numerous in the red sandstone and coal strata. In the genus *asterolepis*, one of the earliest as well as one of the largest of the ganoids, the bony plates which covered the head are ornamented with star-like markings, and the scales of the body are delicately carved; Hugh Miller says its cranial bucklers have been found in the flag stones of Caithness, "large enough to cover the front skull of an elephant, and strong enough to have sent back a musket bullet as if from a strong wall." It must have equalled in size the largest alligator, and its teeth throughout the jaw had the reptilian peculiarity of being received into deep pits opposite, causing them when the mouth is shut to lock like the serrations of a bear trap. The genus *holoptychius* was of very large size, with rough scales several inches in diameter, the cranial bones sculptured like those of the crocodile, and conical teeth larger than those of any living reptile. The *H. (rhieodus) Hibberti*, the largest of about 20 described species, was of such a giant size that the words applied in Job to leviathan might appropriately be given to it; this reptilian fish must have been 40 feet in length, with teeth 8 times larger than those of the largest crocodile, and covered with an impenetrable coat of mail. There were several smaller holoptychians in the red sandstone, even more strongly armed than this giant of the coal period.—For further details on fossil ganoids of these and other families, the reader is referred to the great work of Prof. Agassiz on "Fossil Fishes;" and for a popular description of the most interesting genera to the charming writings of Hugh Miller, especially the "Testimony of the Rocks," "Footprints of the Creator," "Old Red Sandstone," and "Popular Geology."

GANS, EDUARD, a German jurist, born of Jewish parents in Berlin, March 22, 1798, died there, May 5, 1889. He studied successively in the universities of Berlin, Göttingen, and Heidelberg, and became early associated with Hegel, whose philosophical opinions he shared, and by whose influence he conceived a strong antipathy to the historical school of jurisprudence, then supported by the great names of Savigny and Hugo. He became doctor of law in 1820, and resided for several years in Paris and London, and in 1826 was appointed professor of law in the university of Berlin. He soon published a work on the "Law of Inheritance in its Historical Development," in which he attacked the historical school, and aimed to treat the science of law according to the principles of the Hegelian philosophy. His clear and vivacious manner of lecturing was strikingly in contrast with the monotonous gravity usual in German universities, and gained for him crowded audiences. He began a course in 1835 upon the history of the last 50 years, but was obliged by the government to suspend it. He was one of the founders in 1826 of the *Berliner Jahrbücher*, and has left many works on juridical, historical, political, and

æsthetic subjects. He was among the most active of those who prepared the posthumous edition of the complete works of Hegel, and the "Philosophy of History" was really the work of Gans, since Hegel left only its introduction.

GANSEVOORT, PETER, an American officer, born in Albany, July 17, 1749, died July 2, 1812. In 1775 he received the appointment of major in the 2d New York regiment, and joined the army which under Montgomery invaded Canada. In March, 1776, he was made a lieutenant-colonel, and at a later period of the same year he was appointed to the command of Fort George. In 1777 he was placed in command of Fort Stanwix, which he gallantly defended against a vigorous siege of 20 days by British and Indians under St. Leger, and received the thanks of congress for having thereby prevented the coöperation of that general with Burgoyne, and contributed to the defeat of the latter. In 1781 the state of New York raised him to the rank of brigadier-general, which he held till the termination of the war. He afterward filled various important offices under the federal government. He was successively commissioner of Indian affairs, commissioner for fortifying the frontiers, and military agent. In 1809 he was appointed brigadier-general in the U. S. army.

GANYMEDE, a Trojan prince, son of Tros and brother of Ilus, was the most beautiful of mortals, and was carried off, according to the legend, by the eagle of Jupiter, to succeed Hebe as cup-bearer to the gods on Olympus. Astronomers have placed him among the constellations under the name of Aquarius, or the water-bearer. He is represented in the fine group of statuary in the Pio-Clementine museum at Rome, and in the group of "Hebe and Gany-mede" by Crawford, at Boston.

GAR FISH, or GAR PIKE (*lepidosteus*), a ganoid fish, belonging to the same order as the *polypterus* of Africa, the mud fish (*amia*) of America, and the sturgeon family; it is the only genus of its family, and there are more than 20 species, all American. As in other ganoids, the body is covered with smooth enamelled scales, of a rhombic form, arranged in oblique rows, and so hard that it is impossible to pierce them with a spear; this enamel is like that of teeth, and the scales contain the fluorine and lacunæ of ordinary bone structure. The internal skeleton is bony; the snout is elongated, varying in width according to the species; both jaws and nasal bone are covered with small teeth, with long and pointed ones along the edge; the teeth are in double rows of unequal size, the larger resembling those of reptiles, and the smaller fish-like, the front ones of the lower jaw being received into sheath-like cavities in the upper, as in the alligators; their structure resembles that of the labyrinthodont reptiles, having processes of the pulp cavity radiating toward the circumference; the vertebræ also present a reptilian arrangement in having ball and socket articulations, the anterior surface of each bone being convex and the posterior concave; this

gives greater flexibility to the spine, and enables this genus (alone among fishes) to move the head independently of the trunk, and also to retain the posterior part of the body in a curved position. The gills on the 4 arches have a perfect bifoliate structure, and behind the last and the hyoid bone there is the usual fissure; there is a respiratory opercular gill as well as a pseudobranchia, but no blow-hole; branchiostegal rays 3, the membrane passing from side to side, undivided. The anterior edge of all the fins is protected by hard spiny scales, and all the fin rays are articulated; the dorsal and anal fins are far back, and nearly opposite one another; the caudal fin is abruptly truncated, and its rays are inserted partly at the end of and partly beneath the extremity of the spine. There are the usual numerous valves in the arterial bulb, no decussation of the optic nerves, and abdominal ventral fins; the stomach is continued without cæca to a slender twice-folded intestine, which has a slightly developed spiral valve, but numerous pancreatic cæca; the long air or swim bladder is muscular, freely supplied with blood from the aorta, divided into cells like the lung of a reptile by muscular bundles, and opening into the throat by a wide duct and long slit guarded by a sphincter muscle; the ovaries are saciform, with oviducts issuing from their middle. Gar fish are not uncommon in the western rivers and northern lakes communicating with the gulf of Mexico and the St. Lawrence, and probably every separate basin and watershed has its peculiar species; Prof. Agassiz has determined 10, 5 pointed-nosed and 5 short-nosed. They frequent shallow, reedy, or grassy places, basking in the sun like the pike, and devouring living prey with great voracity. The manner of seizing prey differs from that usually observed in fishes, and resembles that of reptiles; instead of taking their food at once with open mouth and swallowing it immediately, they approach it sily and sideways, and then, suddenly seizing the fish or other animal, hold it until by a series of movements it is placed in a proper position for being swallowed, in the manner of alligators and lizards; the ball of food is also seen to distend the body as it passes downward, as in snakes. This reptilian fish, like the ichthyoid reptiles, is in the habit of approaching the surface of the water, and of apparently swallowing air; at any rate, a large amount of air escapes from the mouth, most of which had probably been previously swallowed, and a part of which may have been secreted by the lung-like air bladder. As in the *menobranchus* and other fish-like salamanders, this air bladder doubtless performs certain respiratory functions, and perhaps more than in the naked-skinned reptiles; at any rate gar pikes live longer out of water than fishes generally, and to a degree not explicable by any arrangement of the gills. The gar pike and the African *polypterus* (described below) are the only two existing genera of a type of sauroid fishes which were very numerous in the secondary geological epoch, extend-

ing also in diminished numbers through the palæozoic age at a time when reptiles proper did not exist; they are found from the lower silurian strata to the present time, gradually diminishing through the tertiary to the 2 existing genera; they present one of the first steps in the geological succession of bony fishes, at a time when the ctenoids and cycloids had not appeared; after the rhizodont reptiles and the common osseous fishes were created, the ganoids (which Agassiz is disposed to elevate into a class) began to diminish.—The common gar fish (*L. osseus*, Linn.), called also bony pike and Buffalo fish, attains a length of 5 feet. The color is umber brown on the back and head, the sides yellow, and the belly white; there are circular black spots on the caudal, dorsal, and anal fins. It is found in Lakes Erie, Huron, and Champlain, the Ohio and its tributaries, and other western rivers. The great length of its jaws will distinguish it from other species; it is often seen apparently sleeping on the surface, and gently carried round in an eddy for an hour at a time; it leaps often out of water in pursuit of its prey, and is so swift and strong a swimmer as to stem the most furious rapids. The alligator gar fish (*L. ferox*, Raf.) has a shorter head, the jaws forming not quite half the length, broad and flat above; the skin is rough, the scales imbricated and sculptured; teeth numerous, strong, and prominent; the upper jaw, as in the preceding species, expanding into a knob at the end; the color is yellowish brown. It inhabits the Mississippi and Ohio rivers and their tributaries, and is usually from 4 to 6 feet long; according to Rafinesque, it attains a length of 12 feet, and is a match for an alligator; its impervious coat of mail, strong teeth, size, strength, and agility must make it a very formidable fish, though probably not superior to the equally well armed and powerful alligator. It may be well called the shark of fresh water, though not belonging to the placoid group of fishes. A smaller, less common, and flat-headed species is the duck-bill gar (*L. platostomus*, Raf.), found in the western waters; the jaws are shorter, wider, and flatter than in the common gar, and longer and more tapering than in the alligator gar; the head and back are dusky and umber, sides yellowish, abdomen white, iris golden yellow, the dorsal, anal, and caudal fins spotted; a series of obscure circular spots on the median line behind the anal. The length is from 2 to 5 feet. There are several other species described, more or less resembling the above; but these will serve to give an idea of the general characters of this singular fish, the living type of the dominant family of its class during the carboniferous period.—The allied genus *polypterus* (Geoffr.), from the Nile, Senegal, and other African rivers, is characterized by similar enamelled scales, and by a number of finlets extending from the middle of the body to the tail; the throat is covered with hard, nearly immovable plates, which would greatly embarrass respiration were it not for 2 openings

on the top of the head, which answer the purpose of blow-holes and allow the water to pass through them; the lobes of the tail are of unequal size; the abdominal organs occupy a very small space, being packed close to the spine; the upper jaw is not in several pieces, but the mandibles and skull are as in osseous fishes generally; there is no opercular gill, nor pseudobranchia; the nostrils are very complicated, with labyrinthine gill-like folds; the stomach is caecal, the intestine provided with a well-marked spiral valve, and there is a single pancreatic caecum; the air bladder is double, communicating with the throat by a duct opening on the ventral side, and its arteries are formed by the union of the blood vessels coming from the last gill, carrying therefore oxygenated blood.—The *lepidosteus* is by far the best known and most interesting of the sauroid fishes, and has been of such value to palaeontologists that it has been well said by Hugh Miller, in his "Lectures on Geology," that "it would almost seem as if the *lepidosteus* had been spared, amid the wreck of genera and species, to serve us as a key by which to unlock the marvels of the ichthyology of those remote periods of geologic history appropriated to the dynasty of the fish." (For further details on the fossil members of the family, see GANOIDS.)

GARAT, DOMINIQUE JOSEPH, a French writer and politician, born in Ustaritz, Basses-Pyrénées, Sept. 8, 1749, died near that place, Dec. 9, 1838. He was a contributor to the *Encyclopédie méthodique* and the *Mercur de France*. He published an eulogy on L'Hôpital in 1778; was elected to the constituent assembly in 1789; reported the sittings of the assembly in the *Journal de Paris*; succeeded Danton as minister of justice, and informed Louis XVI. of the judgment of the convention. From the ministry of justice he was transferred to the home department. He coöperated with the enemies of the Girondists, tried in vain to save some of the latter, and left office in Aug. 1794. Under the directory, he was sent as ambassador to Naples, where he was ill received. In 1805 he received a mission to Holland. On the downfall of Napoleon he tried every means of propitiating the Bourbons, but in 1816 was excluded from his seat in the institute. He now wrote one of his most interesting books, *Mémoires historiques sur la vie de M. Suard*, and not long afterward retired to his native mountains, where he led an obscure life, devoting his time to religious exercises.

GARAY, JÁNOS, a Hungarian poet, born at Szekszárd, in the county of Tolna, in 1812, died at Pesth, Nov. 5, 1858. His chief productions are the epic poems "Csatár," "Sophia Bosnyák," "The Wife of Frangepán," and "St. Ladislas;" the dramas "Árbooz" and "Elizabeth Báthory;" "The Árpads," a collection of ballads on the history of that Hungarian dynasty; and *Balaton könyve*. He wrote beside numerous other poems, sketches in prose, and contributions to literary periodicals. His historical ballads are particularly popular. His poems have been

collected by F. Ney (5 vols., Pesth, 1858). A selection of them has appeared in a German translation by Kertbeny (2d ed., Vienna, 1857).

GARCIA, DON ANTONIO GUTIERREZ, a Spanish dramatist, born in Chichanas in July, 1813. He arrived in Madrid at the outbreak of the Carlist war, and was drafted into one of the regiments raised to quell the insurrection. Too poor to purchase a substitute, he was about to become a soldier when his tragedy *El trovador* was accepted at the theatre del Principe. The success of this work, which 20 years later furnished the libretto for one of Verdi's most popular operas, was complete, and the author was enabled to release himself from the conscription. He has since produced many other successful plays, among which are enumerated *El paje*, *El rey monje*, and *Magdalena*.

GARCIA, MANUEL DE POPULO VICENTE, a Spanish composer and singer, born in Seville, Jan. 21, 1775, died in Paris, June 9, 1832. Having acquired considerable celebrity as a tenor singer in Spain, he made his début in Paris in 1808, and for many years was a reigning favorite in all the great cities of Europe. He wrote a number of operas, of which the "Caliph of Bagdad" proved the most successful. In 1825 he came to the United States with an opera troupe consisting of himself, his wife, his daughter Maria Felicia, afterward celebrated as Madame Malibran, and several others. The enterprise proved so successful that Garcia extended his visit to Mexico. On the road between Mexico and Vera Cruz he was robbed of all his earnings, and returned to Paris in an impoverished condition. His voice having been impaired by age and fatigue, he established a school of vocal instruction, in which some of the greatest singers of Europe have been educated. He was equally accomplished as an actor and a vocalist.—His son MANUEL GARCIA, born in Madrid in 1805, and formerly a professor in the *conservatoire* at Paris, is one of the best teachers in Europe. He has written *Mémoire sur la voix humaine* (2d ed. 1847); *École de Garcia, traité complet de l'art du chant* (3d ed. 1851; remodelled in 1856 under the title of *Nouveau traité*, &c.); and *Observations physiologiques sur la voix humaine* (in French and English, 1855).—PAULINE VIARDOT, a distinguished singer, born in Paris, July 18, 1821, daughter of Manuel Garcia and sister of Madame Malibran, whom at the age of 4 she accompanied on their musical visit to America. Her precocity was then such that she could speak 4 languages, and 3 years later she had acquired so great a mastery of the pianoforte as to be deemed worthy of the instructions of Liszt. Subsequently her voice gave so much promise that it was determined to cultivate it for the stage. The death of her father in 1832, the frequent absences of her sister, and the absorbing duties of her brother, the professor of singing at the *conservatoire*, deprived her of the benefit of their instruction, and to the development of her vocal organ she was indebted to her mother, who had formerly been an accomplished singer.

By her 16th year her voice became fixed, resembling in its double register of contralto and soprano that of her sister, but more flexible, and comprising a compass of 8 octaves. In May, 1839, she made her début in London in Rossini's *Otello*, and subsequently in Paris, achieving a decided triumph in each instance. In the succeeding spring she was married to M. Viardot, a journalist of Paris. She sang there the next season with increased effect, reviving many recollections of her sister, and for 7 years appeared in Vienna, St. Petersburg, and Berlin, returning to London in 1848. Since that time she has confined herself chiefly to London and Paris; and in July, 1859, she accepted an engagement at the *théâtre lyrique* to make her début in *Orphée*. Her principal parts are Desdemona, Cenerentola, Rosina, Arsace, Norma, Lucia, Leonora, Donna Anna, Iphigenia, Valentine, and more particularly Fides in Meyerbeer's *Prophète*, a part which she may be said to have created, and in which she has never been surpassed. Her dramatic genius is of the first order, and her stage abstraction is so perfect that the actress is lost in the character she is personating. Her versatility is indicated by the wide range of characters she has assumed.

GARCILASSO DE LA VEGA. I. A Spanish lyric and pastoral poet, born at Toledo in 1503, died at Nice in Nov. 1586. His father, who was descended from an ancient family in the north of Spain, was councillor of state to Ferdinand and Isabella, and for some time their ambassador at Rome; his mother, the daughter and sole heir of Fernan Perez de Guzman, belonged to one of the most illustrious families of Spain. At an early age Garcilasso, who had been trained to arms, entered the service of the emperor Charles V. He was in the campaign in the Milanese in 1521, and distinguished himself by his valor at the battle of Pavia in 1525. In 1580 he married Donna Helena de Zuniga, an Aragonese lady; and in 1532 he was at Vienna, where he displayed his courage in battle with the Turks who had invaded Austria under the sultan Solymán. At Vienna, however, he incurred temporarily the displeasure of the empress by promoting the marriage of one of his nephews with a lady of the imperial household, and he was in consequence imprisoned on an island in the Danube, where he wrote a poem contrasting his own desolate situation with the beauty of the surrounding scenery. He was soon released and taken into greater favor than ever. In 1535 he accompanied the emperor on the expedition to Tunis, in which he was severely wounded in the head and arm. On his return to Spain by way of Sicily and Naples he wrote an elegy at the foot of Mount Etna. In the succeeding year he followed the emperor in the disastrous invasion of the south of France. The Spanish army on its retreat was greatly annoyed by the peasantry, 50 of whom posted themselves in a small castle on a hill near Fréjus. The emperor ordered the castle to be stormed. Garcilasso, who commanded a brigade of 80 companies headed

the assault sword in hand, and was the first to mount the wall. He had rashly neglected to wear his helmet, and in the moment of triumph was struck on the head by a stone and fell into the ditch beneath. He was carried to Nice, where he died 24 days afterward. The emperor cruelly avenged the death of his favorite by hanging all the brave defenders of the castle. Garcilasso left an only son, who fell in battle against the Dutch in 1569. Garcilasso's poems were found by the widow of his friend the poet Boscan among her husband's papers, and published with them. "Their character is singular," says Mr. Ticknor, in his "History of Spanish Literature," "considering the circumstances under which they were written; for instead of betraying any of the spirit that governed the main course of their author's adventurous life and brought him to an early grave, they are remarkable for their gentleness and melancholy, and their best portions are in a pastoral tone, breathing the very sweetness of the fabulous ages of Arcadia. They consist of 37 sonnets, 5 canzoni, 2 elegies, an epistle in *versi sciolti*, less grave than the rest of his poetry, and 3 pastorals. His poetry from the first sank deep into the hearts of his countrymen. His sonnets were heard everywhere; his eclogues were acted like popular dramas. The greatest geniuses of his nation express for him a reverence they show to none of his predecessors. Lope de Vega imitates him in every possible way; Cervantes praises him more than he does any other poet, and cites him oftener. And thus Garcilasso has come down to us enjoying a general admiration, such as is hardly given to any other Spanish poet, and to none that lived before his time." The best edition of Garcilasso's poems was published at Madrid in 1765, edited, though it appeared anonymously, by the chevalier Joseph Nicolas de Azara. There is an English translation with a life and an essay on Spanish poetry by J. H. Wiffen (London, 1823). II. A Spanish soldier, and one of the conquerors of Peru, born in Badajoz, died in Cuzco in 1559. He was of the same family with the preceding, and went to Mexico with Pedro de Alvarado, whom he afterward followed in his invasion and conquest of Guatemala. When Alvarado in 1534 invaded the kingdom of Quito, Garcilasso went with him as captain of a company of infantry, and after Alvarado's return to Guatemala remained in Peru and attached himself to the fortunes of Francisco Pizarro, and after his death to those of his brother Gonzalo. He distinguished himself greatly in the contest with the Peruvians and in the civil war that followed the death of Francisco Pizarro. He supported for some time Gonzalo Pizarro in his rebellion against the royal authority; but in the decisive battle of Xaquixaguana, April 9, 1548, he rode over to the royal side at the turning point of the contest, was received with pardon and favor by the viceroy, and appointed governor of Cuzco, an office he held till his death, which, unlike that of most of the companions of Pizarro, took place

in his bed and not by violence. Garcilasso was noted for his humanity to the Indians, and for the effort he made to ameliorate their condition. He married an Indian princess of the blood royal, the niece of Huayna Capac, and granddaughter of the renowned Tupac Inca Ynpaqui. III. Sur-named the Inca, a Spanish historian, son of the preceding, born in Cuzco in 1540, died in Cordova, Spain, in 1616. His early years were passed in Peru, where he was educated in the Roman Catholic religion. In 1560 he went to Spain, where he ever afterward resided. He entered the army, and served as a captain under Don John of Austria, in the war with the Moriscoes. After the war ended he retired to Cordova, and devoted himself to writing American history. His first work, a "History of Florida," appeared in 1605. It is chiefly devoted to the adventures of Fernando de Soto. In 1609 he published the first part of his great work, the "Commentaries on Peru," relating the history of that country under the Incas. In 1616, a few months before his death, he finished the second part, comprising the story of the conquest by the Spaniards. It was published at Cordova the following year. His work gives by far the fullest account of Peru under its native kings, and is in fact the source of almost all our knowledge upon the subject. The author was proud of his descent from the Incas, and obtained much of the material for his history from his mother's family. His "Commentaries" are interesting and valuable, though they contain much that is mere gossip and not a little fable. They have been translated into many languages. An English translation, in 1 vol. fol., by Sir Paul Rycaut, knight, was published at London in 1688, which, though containing numerous errors, is still a favorite with book collectors.

GARD, a maritime department of France, on the Mediterranean, and on the W. bank of the Rhone, near its mouth; area, 2,256 sq. m.; pop. in 1856, 419,697. It derives its name from a small river which rises in the Cévennes, runs through its centre, and falls into the Rhone a few miles above its delta. The Cévennes mountains send ramifications to its centre, while in the S. E. there is a considerable extent of level country, broken by pools and marshes. Iron, argentiferous lead, antimony, zinc, and manganese are mined; coal mines also are wrought, and there are valuable salt marshes on the coast. The arable lands, which comprise scarcely one-fourth of the department, are generally of indifferent quality, and agriculture is backward. The vines are highly esteemed, and olives are grown; but the culture of the mulberry is of paramount importance. Other fine fruits are also abundant. This department ranks among the most industrious in France, and is especially distinguished for its manufactures of silk, beside which it has cotton and woollen mills, tanneries, distilleries, and soap-making establishments. Capital, Nîmes.

GARD, PORT DU, an aqueduct bridge, built over the river Gard, 10 m. N. E. of Nîmes, and one of

the most celebrated relics of Roman power in France. It consists of 3 tiers of arches, one above the other, its entire height being 156 feet from the level of the water. The undermost range consists of 6 arches, through the widest of which the river flows; the middle has 11, and the uppermost 35. This supports a covered canal about 5 feet high and 2 feet wide, which was part of the aqueduct that formerly brought the waters of the Aire and Aure to Nîmes, and other portions of which still remain. The irregular disposition of the arches adds greatly to the picturesque beauty of the structure, which is some 850 feet long. On the invasion of the barbarians, it was partly destroyed; but it is still an object of curiosity and admiration.

GARDA, LAKE (anc. *Benacus Lacus*), the largest of the Italian lakes, situated on the boundary between Lombardy and Venice, between lat. 45° 26' and 45° 54' N. and long. 10° 33' and 10° 54' E. It is 33 m. in length from N. to S., and from 8 to 11 m. in breadth. It is 218 feet above the level of the sea. At its N. extremity the Sarca and some smaller streams discharge their waters into it, while its surplus waters are conveyed to the Po by the Mincio, which issues from its S. E. extremity. It is famous for its fish, especially sardines, the most important, and carp, some of which weigh 80 lbs. Garda, the village from which it takes its name, stands on the E. shore, and was formerly a place of some note.

GARDAIA, or GUARDEIA, a town of Algeria, in the province of Algiers, situated in the oasis of Wady-Nizab, in the Sahara, lat. 31° 57' N., long. 2° 50' E. It is well fortified, having a wall with battlements and 9 large towers, each of which is capable of holding from 300 to 400 men. Ten gates give entrance to the town, which contains a mosque of vast size and 5 smaller ones, beside a Jewish synagogue. The government is nominally administered by a national assembly, presided over by a chief, but the latter is little more than the mouthpiece of the high priest, whose advice has all the force of law. A flourishing trade is carried on with Tunis, Algiers, Bou Sada, &c., in corn, butter, groceries, oil, pottery, and negro slaves. The suburbs of the town contain extensive vineyards and orchards. Rain is almost unknown, but there are numerous wells, some of which are 900 feet deep. On a neighboring eminence are the remains of a large tower supposed to have been built by the Romans. The oasis in which Gardaia is situated submitted to French rule in 1853.

GARDEN. See HORTICULTURE.

GARDEN, ALEXANDER, a British physician and naturalist, born in Scotland in 1728, died in London in 1792. He studied philosophy in the university of Aberdeen, and medicine under Dr. John Gregory, and emigrated to South Carolina near the middle of the century. He acquired a fortune by the practice of physic in Charleston, and a high reputation by his studies in botany and other sciences. In 1754 he declined a professorship in the college recently es-

tablished in New York city. He was a correspondent of Linnaeus, who gave the name of *Gardenia* to one of the most beautiful and fragrant of flowering shrubs. He published accounts of the pink root (*spigelia Marilandica*), of the *helesia*, of the male and female cochineal insects, of the mud *inguana*, or siren of South Carolina, an amphibious animal, of 2 new species of tortoises, and of the *gymnotus electricus*. Returning to England in 1783 on account of his health, he became one of the vice-presidents of the royal society, of which he had before been elected a member.

GARDEN, ALEXANDER, an officer of the American revolution, in Lee's famous legion, died in Charleston, S. C., about 1825, at an advanced age. He was for a time aide-de-camp to Gen. Greene. He wrote "Anecdotes of the Revolutionary War in America, with Sketches of Character of Persons the most distinguished in the Southern States for Civil and Military Services" (1st series, Charleston, 1822; followed by a second series), which is one of the authorities for the history of the period, containing information hardly to be found elsewhere.

GARDINER, a city of Kennebec co., Me., on the W. bank of the Kennebec river, 12 m. below Augusta, at the head of summer navigation, and on both sides of the Cobboscontee; pop. in 1850, 6,486, since which time a part of its territory has been incorporated with other townships. It is largely engaged in manufactures, for which the falls of the Cobboscontee afford great advantages, and it contains 6 saw, shingle, lath, and clapboard mills, 2 large paper mills, a woollen factory, a foundery, 2 machine shops, 3 tanneries, a pottery, and 2 grist mills. There are 10 churches (2 Baptist, 1 Christian, 1 Congregational, 1 Episcopal, of which the bishop of the diocese of Maine is rector, 1 Freewill Baptist, 1 Methodist, 1 Roman Catholic, 1 Swedenborgian, and 1 Universalist), a high school, a newspaper office, 8 banks with an aggregate capital of \$250,000, an alms house, and a mechanics' association with a small library. The mansion of Robert Hallowell Gardiner, which is within the limits of the city, is one of the most magnificent in the state. About 6,000 tons of shipping are owned here, one-half of which is employed in the southern and foreign trade. A bridge 900 feet long connects Gardiner with Pittston on the opposite bank of the Kennebec. The Kennebec and Portland railroad passes through the city.

GARDINER, JAMES, a Scottish soldier, born in Carriden, Linlithgowshire, Jan. 11, 1688, killed Sept. 20, 1745. At the age of 14 he obtained a commission in the Dutch service. He afterward entered the English army, and was present at the battle of Ramillies. In 1780 he was made lieutenant-colonel, and in 1745 commanded a regiment at the battle of Prestonpans, where he was slain. The author of "Waverley" describes the manner of his death with all the minuteness of historical detail and all the embellishments

of romance. In his youth he led a dissipated and reckless life, but in his latter days he became an exemplar of Christian piety and worth. His life has been written by Dr. Doddridge.

GARDINER, STEPHEN, an English Roman Catholic prelate, born at Bury St. Edmund's, in 1483, died Nov. 12, 1555. He was educated at Cambridge, became secretary of Wolsey, and was soon in high favor with Henry VIII. In 1527 he was sent to Italy to procure the pope's consent to the divorce of Queen Catharine. His mission proved unsuccessful, but while at Rome he rendered important services to Wolsey. On his return he was intrusted with the conduct of the divorce case, and successively made secretary of state and (in Nov. 1531) bishop of Winchester. He endeavored to convince the king of the impolicy of breaking with the pope, and of the propriety of punishing those who denied the bodily presence of Christ in the eucharist. The downfall of Cromwell, who had succeeded Wolsey as favorite, added for a time to the influence and power of Gardiner. But the king began at length to lean toward the reformers, and the refusal of Henry to permit the arrest of Catharine Parr for religious contumacy, demonstrated the decline of that prelate's power. On the accession of Edward VI., Gardiner, refusing to approve of the articles and injunctions issued by the new council, was committed first to the Fleet prison, and then, after a short release and new provocation, to the tower, where he was confined till the reign of Mary, when he was restored to liberty and raised to still greater power than ever, being made lord chancellor. The Protestant persecution which took place during his administration has been generally ascribed by Protestant writers to his counsel, but according to Lingard, "more from conjecture and prejudice, than from real information." He is said to have exclaimed on his deathbed: *Erravi cum Petro, sed non flevi cum Petro* ("I have erred with Peter, but I have not wept with Peter").

GARDINER, SYLVESTER, an American physician, born in Kingston, R. I., in 1717, died in Newport, R. I., Aug. 8, 1786. He studied medicine in London and Paris, subsequently practised his profession in Boston, and opened there a drug establishment, from which the New England colonies were chiefly supplied. He was one of the early promoters of inoculation for the small pox, and a liberal contributor for the erection of King's chapel, Boston. He became possessed of large tracts of land in Kennebec co., Me., and about the middle of the century was instrumental in establishing there the settlement of Pittston, a portion of which was subsequently set off into a separate town, under the name of Gardiner, where he built and endowed Christ church. He retired from Boston on its evacuation by the British troops, but returned to the United States at the close of the revolutionary war, and passed the rest of his life here.—JOHN, son of the preceding, an American advocate, born in Boston

in 1731, drowned off Cape Ann, Oct. 1793. He studied law at the Inner Temple, London, and was admitted to practise in the courts at Westminster hall, where his abilities attracted the notice of Lord Mansfield. He formed an intimacy with Churchill and Wilkes, and was junior counsel of the latter at his trial in 1764, and also appeared for Beardmore and Meredith, who for writings in support of Wilkes had been imprisoned on a general warrant. In 1766 he procured the appointment of attorney-general in the island of St. Christopher, where he remained until after the American revolution, when he returned to Boston. After residing there a few years, he removed to Pownalborough, Me., which place he represented in the Massachusetts legislature until his death. As a legislator he distinguished himself by his efforts in favor of law reform, particularly the abolition of special pleading, and the repeal of the statutes against theatrical entertainments. In connection with the latter subject he published a "Dissertation on the Ancient Poetry of the Romans," and an accompanying speech. The abolition of the law of primogeniture in Massachusetts was due to his efforts. He was one of the most influential of the early Unitarians of Boston, and participated in the transformation of King's chapel from an Episcopal into a Unitarian Congregational church.—JOHN SYLVESTER JOHN, son of the preceding, an American clergyman, born in Haverford West, South Wales, England, in June, 1775, died in Harrogate, England, July 29, 1830. He accompanied his father to the West Indies, and subsequently studied in Boston, and in England under the celebrated Dr. Parr, with whom he remained 6 years. Returning to America, he became a candidate for holy orders in the Protestant Episcopal church, and in 1787 was ordained by Bishop Provoost of New York. In 1805 he became rector of Trinity church, the chief Episcopal parish in Boston, with which he remained connected until his death. He was an accomplished classical and belles-lettres scholar, and a forcible preacher. In the establishment of the "Boston Anthology and Monthly Repository," for which he was a frequent writer, he contributed materially to the dissemination of literary taste and culture in Boston. He was also one of the founders of the Boston Athenæum. He wrote the "Jacobiniad," a satire in prose and verse directed against the liberal clubs of Boston, to which, being in politics a strong federalist, he had an antipathy.

GARIBALDI, GIUSEPPE, an Italian partisan general, born in Nice, July 4, 1806. His father educated him to his own profession, that of a mariner. From his earliest childhood he was remarkable for his affection toward his parents and his sincerity to his companions; while a mere boy, at the risk of his own life, he rescued from drowning a poor washerwoman, and in after life he performed similar actions on several occasions. His second voyage was to Rome, when the condition of that capital made

a deep impression on his mind, and led him into those revolutionary views which, in Feb. 1834, resulted in his exile from Italy. He first went to Marseilles, and earned his living by making voyages to various ports. Having been left sick at Constantinople, he became a teacher till he could find an opportunity to reëmbark for Marseilles, whence he sailed for Tunis and thence for Rio Janeiro. At Rio he met Rosetti, with whom he entered into a commercial partnership, but soon discovered that neither of them was suited for a merchant. About this time Zambeccari arrived in Brazil from Uruguay, then fighting for her independence; becoming acquainted with Garibaldi and Rosetti, he persuaded them to espouse the cause of that republic, and Garibaldi, with 20 companions under his command, embarked in a small craft which he named the *Mazzini*. In an engagement with two launches, which he beat off, he received a gunshot wound in the neck, which nearly proved fatal. He landed at Gualaguay on neutral soil, where he was treated with some outward respect and consideration, but he soon discovered that he was to a certain extent a prisoner, being prohibited from moving more than a short distance from the city. He endeavored to escape, but being betrayed by his guide and retaken, he was brought back bound hand and foot, and was tortured nearly to death with the view of extorting from him the names of those who had favored his flight. Two months later he contrived to reach Montevideo, where he found his friend Rosetti, and the two returned to Uruguay and joined a land expedition under Bento Gonzales, in which Garibaldi distinguished himself. Until the termination of the war he was employed in the service of the republic, chiefly at sea, though sometimes on land. Prior to the cessation of hostilities Garibaldi married a South American woman of extraordinary energy and devotion, and she from that time became the companion of all his dangers and privations by sea and land. After the war he returned to Montevideo and taught mathematics, till Rosas the dictator of Buenos Ayres declared war against the republic. The commencement of the war was disastrous; the city itself was besieged, many were seized with panic, the minister of war Vidal robbed the treasury and fled, and public affairs seemed to be on the brink of ruin. Garibaldi organized a flotilla, recommended the formation of an Italian legion (the command of which was conferred on Auzani), and though especially charged with the defence by sea, he frequently fought with and commanded the Italian legion. Montevideo was saved. In the spring of 1848 Garibaldi sailed from South America with a portion of the Italian legion, and on arriving in Piedmont placed himself at the disposal of Charles Albert, by whom he was coldly received. A few days later, the king being defeated, Garibaldi with a few resolute republicans prolonged the resistance until forced across the frontier by a superior Austrian detachment.

Returning to Nice to his mother, wife, and children, his repose was but short. In the autumn he went to Bologna, where, though the people wanted him, the papal government rejected him. On the flight of the pope the new executive gave to Garibaldi a command, sending him to watch the Neapolitan frontier near Rieti, in which situation he remained till the spring of 1849, when the first act of Avezzana, the new minister of war, was to call Garibaldi to Rome and adequately arm and provide for his men. The French expedition to restore the pope having appeared before Rome on April 30 (8,000 infantry, 2 squadrons of cavalry, and 12 guns), Garibaldi was, with 1,200 men, posted in some villas outside the gates. Notwithstanding the disparity of numbers, he attacked the right wing of the French, when Avezzana, who commanded in chief, seeing from the city wall the peril of the Italians, despatched 1,500 men to his succor; whereupon Garibaldi charged the French so vigorously with the bayonet as completely to break them, pursued them several miles, and returned with 800 prisoners. The Neapolitans now threatened Rome, and these were twice beaten by Garibaldi, at Palestrina and Velletri. The French, strongly reinforced, having on June 30 gained a footing inside the wall, the republican triumvirate abdicated. In this moment of general depression Garibaldi resolved to continue the struggle in the open country, and consequently he issued the following proclamation: "In recompense for the love you may show your country I offer you hunger, thirst, cold, war, and death; who accepts these terms, let him follow me." He left Rome to try to penetrate to Venice with about 4,000 men, of whom 800 were mounted, and marching by Tivoli to Terni met the second Italian legion, which was awaiting him. Thence he took to the left to avoid an Austrian corps, but lost many men at Orvieto by a French column. The population was favorable, but being disheartened remained passive; the enemy in immensely superior numbers was fearful and over cautious, and never accepted a general engagement. Garibaldi displayed a wonderful talent in advantageously posting his men at every halt (never in a city), and in so adroitly manœuvring as to extricate himself and leave his enemy behind him every time he appeared to be surrounded. At St. Angelo in Vado some detachments in the city were cut off, which was the only serious loss he sustained. On July 30 he reached San Marino, his force being reduced to 1,800 men, and there he found in his front a fresh Austrian army in addition to the 13,000 pressing on his rear. Terms were now offered, to the effect that there should be a general amnesty and all should return home, the arms being surrendered to the republic of San Marino. Such conditions would have been accepted had a few French belonging to the second legion been permitted to return to Switzerland; but as it was insisted that they should be sent to Rome, where the French

might maltreat them, the offer of the Austrians was rejected without hesitation, and at night about half the force (the rest chose to surrender) made their way toward Cesena; and though vigorously pursued, the remnant, 290 in number, embarked from Cesenatico in some fishing boats on Aug. 2. Making their way toward Venice (then besieged) with the intention of eluding the blockading squadron, the little band was toward nightfall descried by the Austrian fleet in the Adriatic, and the small craft of the patriots were scattered during the night, some captured, and others run ashore. In the boat with Garibaldi were his wife and a few of the most compromised, Ugo Bassi, Ciceroacchio, &c.; and these gained the shore and dispersed in twos and threes to avoid the vigilance of the pursuit. Two days later Anna Garibaldi, who had refused to leave her husband, being worn out by fatigue, died, leaving Garibaldi oppressed with grief. In this state of utter wretchedness, with nothing but his indomitable courage to sustain him, he made his way from the east to the west coast of Italy, while the punishment of death was decreed for whosoever gave him bread, water, or shelter. From Tuscany he embarked for Spezia, and at Chiavari in the states of Sardinia he was arrested and conducted to Genoa. Banished from the states of Sardinia, he arrived at New York in the summer of 1850, declined the public reception offered him, and earned a living by making candles in a manufactory on Staten island till an opportunity occurred of resuming the occupation of a mariner. He made some voyages in the Pacific, and in about 3 years returned to New York in command of a Peruvian bark. Having lost his mother, to whom he had confided the care of his 8 children, he accepted the invitation to return to Nice, where he lived in retirement. In the beginning of 1859, on the breaking out of the war with Austria, he was invited by the Sardinian government to form a corps, since celebrated as the "Hunters of the Alps" (*Cacciatori delle Alpi*). Detached from the rest of the army, he crossed over on its extreme left into northern Lombardy, with a comparatively small force, beat several Austrian detachments, entered, the foremost of the allies, Varese, Lugano, Como, Bergamo, and Brescia, and rendered the most important services to the Italian cause throughout the war.

GARLAND, HUGH A., an American author and politician, born in Virginia, June 1, 1805, died in St. Louis, Mo., Oct. 14, 1854. He was graduated at Hampden Sidney college in 1825, and in 1826 was chosen professor of Greek in that institution. He studied law, and in 1830 resigned his professorship, and in the following year began to practise at the bar in Mecklenburg county. For 5 years he was a member of the Virginia legislature, and actively supported the democratic party. In 1838 he was chosen clerk of the house of representatives at Washington. In 1839, when the house met, Dec. 2, it was found that there were present 119 demo-

crats and 118 whigs, beside 5 whigs from New Jersey whose seats were contested. Their admission to vote for speaker would have secured to the whigs the organization of the house. In accordance with custom, Mr. Garland, as clerk of the last house, opened the session by calling the roll of members. When he came to New Jersey he called one member whose seat was not contested, and said he should pass over the other 5, as he did not feel authorized to decide whether or not they were entitled to seats. This gave rise to a great uproar and confusion, which lasted till Dec. 5, when it was terminated by the interposition of John Quincy Adams, and his election as chairman *pro tempore*. In 1841 Mr. Garland returned to Virginia, and settled on a farm near Petersburg. Engaged unsuccessfully in mercantile business, he lost nearly all his property, and in 1845 he went to St. Louis, and resumed practice as a lawyer. At the time of his death he held a high rank at the bar. Mr. Garland was the author of a "Life of John Randolph" (2 vols. 8vo., New York, 1850).

GARLIC, the bulb of the *allium sativum*, a plant of the same genus as the onion (*A. cepa*) and the leek (*A. porrum*). The plant is perennial, and grows wild in the southern parts of Europe. In most other countries it is cultivated, and has been esteemed from the remotest times as an article of food or as a condiment, and also for the sake of its medicinal qualities. The bulbs, 5 or 6 in number, are found clustered around the base of the stem, enclosed in a common membranous covering, by which they are concealed from view. They are taken up attached to the stem, and when dried in the sun are tied together in bunches like onions. The small bulbs are called cloves of garlic. They are of oblong shape, of the strong peculiar odor called alliaceous, and have a bitter and acrid taste. A highly viscid juice may be expressed from them, so tenacious that when dried it makes a cement for porcelain. By distilling the bulbs with water a very volatile essential oil is obtained, which possesses in a high degree the peculiar properties of the bulbs. It is of so acrid a nature that it will even raise blisters upon the skin. Sulphur is detected in this oil combined with a radical called allyle, consisting of C, H, S. When garlic is used as food or medicine, this oil is rapidly absorbed, and its presence is soon perceived in the breath and in the secretions of the body. It is so penetrating, that when garlic is externally applied, as to the soles of the feet, the smell is said to be observed in the breath and perspiration. Its moderate use is thought to be beneficial for its stimulant properties in quickening the circulation, exciting the nervous system, &c. As a medicine it is most employed in external applications, as a sedative in fevers, and in nervous and spasmodic disorders of children.

GARNET, the name of a mineral species, presenting many varieties; also applied by Dana to designate a section of the silicates; and in

geology it is the name of a rock made up of some variety of the mineral. The garnet is supposed to have been sometimes included by the ancients in their names *carbunculus* and *hyacinthus*. In its more perfect forms it is a gem, and when cut and polished bears some resemblance to the ruby in color, transparency, and lustre. Some of the precious varieties are distinguished by the names Syrian and oriental, and also almandine, from Alabanda, the place where, in the time of Pliny, they were cut and polished. These and the black varieties also have been much used in Europe, strung together like beads for necklaces. Those most esteemed in jewelry are obtained from Ceylon, Pegu, and Greenland. A single crystal of only $8\frac{1}{2}$ lines by $6\frac{1}{4}$ has been sold for about \$700. Its crystals are rhomboidal and trapezoidal dodecahedrons and variously modified forms. Its hardness is from 6.5 to 7.5; specific gravity 3.15 to 4.3. It is met with of various colors, as red, brown, black, yellow, white, and green, and with a vitreous or resinous lustre. According to its composition it has been divided into 6 sub-species, all of which pass into one another by insensible shades of difference; they are all silicates of different protoxides or peroxides; as: 1, the alumina-lime garnet, a silicate of alumina and lime, of which the cinnamon stone or essonite is an example; 2, the alumina-magnesia garnet; 3, the alumina-iron garnet, a silicate of the protoxide of iron and lime, as almandine and a variety of the common garnet; 4, alumina-manganese garnet, called also manganese garnet; 5, iron-lime garnet, composed of silicates of the peroxide of iron and of lime, as the black garnet and a variety of the common garnet; 6, lime-chrome garnet, as the emerald green ouvarovite of Russia. The silicic acid in these varies from 84 to 44 per cent. Their composition is represented by the general formula $3RO, SiO_2, R_2O_3, SiO_2$, in which RO represents either one of the protoxides that may be present, and R_2O_3 , either the alumina (Al_2O_3), or the peroxide of iron (Fe_2O_3), or of chrome (Cr_2O_3). Garnets are easily melted by the blowpipe; and some varieties, as the melanite or black garnet, found in the lavas of Vesuvius, appear to be a direct product of the fusion of their ingredients. The iron-lime garnets, of which this is a variety, containing from 20 to 30 per cent. of peroxide of iron, and about the same proportion of lime, might be advantageously employed both as iron ore and flux in the manufacture of iron, mixed with other ores more rich in iron and deficient in silica. They frequently occur in the vicinity of iron ores, and in beds of great extent, forming a true garnet rock, and from their highly ferruginous appearance have in some instances been mistaken for iron ores; though when worked they have been condemned from their true character not being understood. Garnet of this character is found in the highlands on the west side of the Hudson river, containing by analyses of two varieties by Dr. A. A. Hayes:

	1.	2.
Quartz and silica	83.70	41.88
Lime	21.25	29.00
Magnesia	8.10	trace
Alumina	11.06	6.48
Peroxide of Iron	24.78	29.00
Peroxide of manganese	0.98	trace
Total	99.77	98.76

Similar qualities are also met with in the iron region of New Jersey. They frequently contain traces of titanium and of tin.—Crystals of garnet are common in the granite rocks and the metamorphic slates and limestones in almost all localities where these are found; but when most abundant and large, they are commonly rough and unsightly. In the gold region they abound in the slates, and in some instances where the rock that contained them has crumbled away they are left loose upon the surface, so that they might easily be shovelled up by cart loads.

GARNETT, JAMES MERCEUR, an American politician and agriculturist, born at Elmwood, Essex co., Va., June 8, 1770, died there in May, 1848. He was for several years a member of the legislature of Virginia, and was a representative in congress from 1805 to 1809. In 1829-'30 he was a member of the convention which revised the constitution of Virginia. He acted with the democratic party, and was engaged in several political controversies of note in their day. One of these was with Mathew Carey the protectionist, in which Mr. Garnett contended for free trade. The greater part of his life was zealously devoted to the cause of education and the promotion of agriculture. He maintained a school at his own house for 12 years, and was foremost in introducing improved methods of education into Virginia. For more than 20 years he was president of the agricultural society of Fredericksburg, and exerted himself strenuously for the formation of the United States agricultural society, of which he was chosen the first president. He was a fluent and racy writer, and his contributions to various journals on agricultural subjects were widely read and exercised great influence.

GARNIER, ADOLPHE, a French eclectic philosopher, born in Paris, March 27, 1801. He aided Jouffroy in translating the works of Thomas Reid, was in 1827 appointed professor of philosophy in the college of Versailles, and afterward promoted to a chair in Paris. He meanwhile published his *Précis de psychologie*, and a complete edition of the philosophical writings of Descartes. In 1838 he succeeded Jouffroy as lecturer on philosophy at the Sorbonne, and in the following year produced his *Comparaison de la psychologie et de la phrénologie*. He published in 1850 a *Traité de morale sociale*, and in 1853 a *Traité des facultés de l'âme*, which won a prize from the French academy.

GARNIER, CHARLES GEORGES THOMAS, a French author, born in Auxerre, Sept. 21, 1748, died in the same place, Jan. 24, 1795. He was educated at the college of Plessis, and became an advocate, though the weakness of his voice

did not permit him to speak in public. In 1770 he began to publish in the *Mercur de France*, under the nom de plume of "Mademoiselle Ragner de Malfontaine," dramatic proverbs, whose ingenuity and sprightliness attracted the attention of the governess of the young princess de Condé, and Garnier was soon engaged to write proverbs to be acted for the special amusement of the princess at the abbey of Panthemont. In 1791 he was made *commissaire du roi* at Paris, and in 1798 was sent by the revolutionary government to his native city as commissioner, which post he held till his death. Among his works are *Nouveaux proverbes dramatiques* (8vo., Paris, 1784), and various novels. He also collected and edited the *Cabinet des feux* (41 vols. 8vo., Paris, 1785); *Voyages imaginaires, songes, visions et romans merveilleux* (39 vols. 8vo., Paris, 1787).

GARNIER, CLÉMENT JOSEPH, a French political economist, born at Beuil in Sardinia (which then belonged to France), Oct. 3, 1813, studied at the superior school of commerce in Paris, and was for some time professor and director of studies there. From 1846 to 1856 he filled the newly created chair of political economy in the school of roads and bridges, and since the latter year he has officiated in the same capacity in the school of commerce. From 1845 to 1855 he edited the *Journal des économistes*. In 1846, during the free trade agitation in England, he formed in concert with Bastiat, Chevalier, Faucher, and others, a free trade association, of which he became secretary; but it was dissolved in 1848. In 1842 he had contributed to the establishment of the society of political economy, and still officiates as its perpetual secretary. He was also one of the founders of the peace congress in Paris (1849), and a member of the statistical congress at Brussels (1853), and at Paris (1855). In 1853 he established in concert with M. N. Bourgeois the *Nouveau journal des connaissances utiles*. The 3d edition of his *Éléments d'économie politique* appeared in 1856.

GARNIER, GERMAIN, a French political economist, born in Auxerre, Nov. 8, 1754, died in Paris, Oct. 4, 1821. He was secretary to Adelaide, aunt of Louis XVI., and was noted for slight Anacreontic verses, when in 1790 he became a member of the monarchical club formed in opposition to that of the Jacobins. He emigrated in 1792, returned in 1795, became a prefect under the consulate, and afterward a senator, count of the empire, and president of the senate (1809 to 1811). In 1814 he favored the restoration, was made peer of France, removed from Paris during the Hundred Days, and became minister of state after the second restoration. In political economy he belongs to the school of Quesnay. His most esteemed works are an *Abrégé des principes de l'économie politique* (Paris, 1796); the best French translation of Adam Smith, to which he added many notes (Paris, 1805); and a *Histoire de la monnaie depuis les temps de la plus haute antiquité jusqu'au règne de Charlemagne* (Paris, 1809). He

also translated some of the novels of Godwin and Mrs. Radcliffe.

GARNIER-PAGES, ÉTIENNE JOSEPH LOUIS, a French politician, born in Marseilles, Dec. 27, 1801, died in Paris, June 28, 1841. His family being reduced in circumstances, he was educated amid the hardships of poverty. In 1822 he was bookkeeper in a commercial house with a salary of \$300 a year. In 1825 he attended lectures at the *école de droit*, and was admitted to the bar. He became a member of the celebrated association *Aide-toi, le ciel t'aidera*, and actively participated in the revolution of July, 1830. In 1831 he was elected to the chamber of deputies, and took his seat among the members of the opposition. He slowly established his influence by boldness of opinion and moderation of speech. He was not a brilliant orator, but an excellent debater, especially upon financial matters. His ultimate aim was a republic; but he desired to obtain his object by gradual reform. His career was cut short by an early death.—**LOUIS ANTOINE**, a French politician, half brother of the preceding, born in Marseilles in 1806. While employed as a merchandise broker in Paris he found time to attend with his brother at the sittings of the secret associations which aided in the revolution of July, 1830. He organized the means of resistance among the workmen of the district where he resided, and bore arms himself. In 1842 he was elected to the chamber of deputies, and became at once one of the staunchest members of the opposition, and in 1847 was one of the most active promoters of the reform agitation. He was conspicuous among those who in Feb. 1848, appeared at the banquet of Paris, in spite of the prohibition of the government. On Feb. 24 he was appointed a member of the provisional government, then mayor of Paris, and on March 5 he succeeded M. Gondchaux as minister of finance. As a member of the constituent assembly, he submitted a remarkable report on the financial situation of the republic, and left the finance department to enter the executive commission of government appointed by the assembly. On the insurrection of June this commission had to resign its power to Gen. Cavaignac; and Garnier-Pagès, after the expiration of his term as deputy, retired to private life.

GARONNE (anc. *Garumna*), a river in the S. of France, rising in the Spanish valley of Aran, in the central Pyrénées, near the foot of Mt. Maladetta, and flowing N. W. into France, which it enters at a place called Pont-du-Roi, in the department of Haute-Garonne. It runs thence N. E. to Toulouse, whence it flows generally N. W.; it passes the towns of St. Bât, Montrejean, St. Martory, Cazères (where it becomes navigable), Carbonne, Muret, Toulouse, Verdun, Agen, St. Macaire, and Bordeaux, a few miles below which it is joined by the Dordogne and forms the estuary or river known as the Gironde. Its chief affluents on the right bank are the Arége, Tarn, Lot, and Dropt; on the left, the Save, Gimone, Gers, Baise, Avance, and Oiron. Its length is about 352 m., of which 262 are

navigable; but including its feeders, which communicate with 12 departments, the total river navigation of its basin may be stated at 1,000 m. Large vessels can ascend to Bordeaux, where the channel is about 800 yards wide and from 10 to 15 fathoms deep. At Toulouse it is joined by the canal du Midi, by means of which and by this river the Mediterranean is connected with the bay of Biscay. The basin of the Garonne includes a tract of country about 185 m. in average length and breadth. The upper part of its course lies through narrow defiles and is much obstructed; from Toulouse it is broad but shallow, and navigation is more or less impeded by the debris which it brings down, even as far as Marmande, about 50 m. above Bordeaux. Its banks are remarkable for fertility and picturesque scenery.

GARRARD, a central co. of Ky., bounded N. by the Kentucky river, and E. by Dick's river; area estimated at 250 sq. m.; pop. in 1850, 10,287, of whom 3,176 were slaves. It has a hilly or rolling surface, and a soil of more than common fertility, watered by a number of small streams. The staples are grain, horses, cattle, mules, and swine. The productions in 1850 amounted to 84,920 bushels of wheat, 978,875 of Indian corn, 169,940 of oats, 50,150 lbs. of tobacco, and 30,255 of wool. There were 35 corn and flour mills, 8 saw mills, 8 tanneries, 1 newspaper office, 14 churches, and 115 pupils attending public schools. Value of real estate in 1855, \$2,578,678. The county was formed in 1796, and named in honor of James Garrard, of Kentucky. Capital, Lancaster.

GARRETTSON, FREEBORN, a minister of the Methodist Episcopal church in the United States, born in Maryland in 1753, died in New York, Sept. 26, 1827. He entered the ministry in 1775, travelled extensively in several of the states, and in 1784 went as a missionary to Nova Scotia. In 1788 he commenced his labors in the state of New York. In 1791 he married Miss Livingston of Rhinebeck, and confined his subsequent labors to New York, where he was eminently successful. He was a very popular and influential preacher in the Methodist church, and is now frequently referred to as a special friend of the slave, having emancipated a number belonging to him. At his death he made provision in his will for the perpetual support of a missionary.

GARRICK, DAVID, an English actor, born in Hereford, Feb. 20, 1716, died in London, Jan. 20, 1779. His grandfather Garric, or Garrique, was a French Protestant who took refuge in England after the revocation of the edict of Nantes. His father, a captain in the English army, settled at Lichfield on half pay, and with difficulty maintained a family of 7 children. At the age of 10 David was sent to Mr. Hunter's grammar school. He was a lively, volatile boy, a great mimic, and at 11 acted in a play, the "Recruiting Officer," before a select audience with great applause. He was manager of the company, and applied to Johnson for a prologue,

but without success. In 1728 or '29 he went to Lisbon to visit an uncle, a considerable wine merchant. Here he amused dinner parties by repeating verses and popular speeches. But he returned the next year to England, and attended the theatres at London during occasional visits there. At 18 he was one of the 8 scholars at Dr. Johnson's academy. In March, 1736, he set out with his master for London. Johnson and Garrick entered the metropolis with little money and a single letter of introduction. Garrick now proposed to study law; he even entered at Lincoln's Inn, but poverty interrupted his studies. His uncle soon after died, leaving him £1,000, and he next commenced business as a wine merchant, in connection with his brother Peter, but the partnership was soon dissolved. Foote used to say that he remembered Garrick when, "with 8 quarts of vinegar in his cellar," he called himself a wine merchant. He was now constant at the theatres. He wrote theatrical criticisms, practised declamation, and in the summer of 1741 made his first appearance as an actor at Ipswich, under the assumed name of Lyddal, taking the part of Aboan in the play of "Oroonoko." His face was blackened, and he trembled with diffidence; but the provincial audience was delighted. He soon tried comic parts, and crowds came to see him; as Harlequin his success was complete. But when he applied for employment to the managers of Drury Lane and Covent Garden, both rejected him. He made his first appearance in London at a little playhouse in Goodman's fields, Oct. 19, 1741, acting Richard III. to a small audience with great effect. His fame spread rapidly; the great theatres were deserted, and all the fashion came to Goodman's fields; Garrick's natural acting charmed a public weary of the rant and affectation of Macklin or Quin. He next made an engagement at Drury Lane for £500 a year. In 1742 he went to Dublin, and was received with great enthusiasm. In 1748 he gained the friendship of Pitt, afterward earl of Oatham, and of Lyttleton. Pitt wrote him complimentary verses, and Lyttleton praised him in his "Dialogues of the Dead." Garrick was now the first of English actors; he excelled in comedy, farce, tragedy, and pantomime. In 1745 he again visited Dublin, and was for a time joint manager there with Mr. Sheridan. In 1747 he bought a half interest in Drury Lane theatre, and on Sept. 20 opened his management with the famous prologue written by Johnson. He soon after brought out Johnson's "Irene" with considerable profit to the author. In July, 1749, Garrick married the German dancer, Mlle. Violette, who is said to have brought him £6,000. She was accomplished, intelligent, and a faithful wife, and survived him till 1822, when she died suddenly at the age of 98. In 1758 Garrick brought out the "Gamester," by Edwin Moore; he refused Home's "Douglas" in 1756. He was singularly sensitive, trembled before adverse criticism, and assiduously courted the critics. In Sept. 1763, he went to the con-

tinent, and was received everywhere with attention and respect. He returned in 1765, and in November reappeared in "Much Ado about Nothing," at the command of the king, amid unbounded applause, having opened the performance with an address to the public which was called for on the 10 succeeding nights. In Sept. 1769, he arranged a jubilee in honor of Shakespeare at Stratford-on-Avon, which continued 8 days, and which he afterward represented for 92 successive nights at Drury Lane. In 1773, his partner, Mr. Lacy, having died, the whole management of the theatre fell to his charge. His health failing, he now seldom acted; and on June 10, 1776, after having played a round of his old and favorite characters, he took his leave of the stage in the part of Don Felix, in the comedy of the "Wonder," the performances being for the benefit of the fund for the relief of decayed actors, which he had originated. A crowded and distinguished audience was present, and he closed the evening with a farewell address which drew tears from them and himself. Having amassed a very considerable fortune, he now retired to enjoy it. His villa at Hampton was adorned with all the charms of luxury and taste. Bishops and princes visited the retired actor, and Hannah More here passed many agreeable hours. His later years were filled with suffering. The gout and gravel, to which he had long been subject, returned upon him with increasing severity. He endeavored to maintain his usual gayety, and was passing the Christmas holidays at the seat of Earl Spencer, when a sudden attack prostrated him. He was carried to his house in the Adelphi, London, and there died. He was buried on Feb. 1, 1779, with great splendor; all that was eminent in London followed the comedian to his grave. He was buried beneath the monument of Shakespeare, and here a monument has been raised to his memory at the expense of one of his admirers, Mr. Albany Wallis. Garrick's talents were singularly versatile. He wrote farces and comic pieces, conversed well, and was a member of the literary club. He succeeded in every kind of acting. His comic turn led him to delight in broad farces, in feats of dexterity and ludicrous transformations. As Hamlet he filled his audience with horror and melancholy; in the part of Lear he rose to the height of tragic power. Yet he labored under several disadvantages. He was of middle size, delicate in form, and quick in movement, wanting that dignity of appearance with which nature has endowed other actors. His memory, too, sometimes failed him, and he would repeat a line before he could recover himself. But his voice was melodious and clear, his countenance animated, and his sensitive temperament, even in his silence, governed the spectator. His thrills of feeling communicated themselves by look, gesture, and position. He felt the emotion he inspired. He was a man capable of many generous acts, somewhat vain, but good-humored and placable, a kind friend, and charitable to

the poor. In spite of a certain want of dignity in his manners, and a constant affectation, he was respected and liked by his contemporaries. Dr. Johnson, who dictated to Davies many particulars of his life, always spoke of him as kind-hearted and honest, as well as great.

GARRISON, WILLIAM LLOYD, an American abolitionist, born in Newburyport, Mass., Dec. 10, 1805. His parents were natives of the province of New Brunswick. His father, Abijah Garrison, was master of a vessel engaged in the West India trade, and a man of some literary ability and taste; but he became intemperate, and, under the influence of that vicious habit, went away from his family while his children were young, and never returned. The mother, left in utter poverty, became a professional nurse, and in 1814 went to Lynn, taking William with her, and placing him with Gamaliel Oliver, a Quaker, to learn the trade of a shoemaker. He was extremely small for his age, and his knees trembled under the weight of the lapstone. His mother, finding that the business did not suit him, sent him back to Newburyport at the end of 3 or 4 months, placing him under the care of Deacon Ezekiel Bartlett. In order to relieve his mother from the necessity of paying his board, he employed himself when out of school in assisting the deacon in his occupation as a woodsawyer, going with him from house to house. At school he was taught reading, writing, ciphering, and a smattering of grammar. In 1815 he went with his mother to Baltimore, where he remained a year, in the capacity of a chore boy, and then returned to Newburyport. In 1818 he was apprenticed to Moses Short, a cabinet-maker, in Haverhill; but, as he strongly disliked the trade, he persuaded Mr. Short to release him. In October of the same year he was indentured to Ephraim W. Allen, editor of the "Newburyport Herald," to learn the art of printing. This occupation suited his tastes; he quickly became an adept at the mechanical part of the business, and when only 16 or 17 years of age began to write upon political and other topics for the "Herald," carefully preserving his incognito. It was a long time before Mr. Allen learned that the correspondent whose communications he eagerly sought and commended was his own apprentice, who often had the satisfaction of putting his own articles into type, and once received through the post-office a letter of thanks from his master, with a request that he would continue to write. He soon commenced writing also for the "Haverhill Gazette," the "Salem Gazette," and the "Boston Commercial Gazette," all of which received his contributions with favor. The editor of the journal last named, Samuel L. Knapp, Esq., appreciated his articles very highly. A series of articles which he wrote for the "Salem Gazette," under the signature of "Aristides," attracted much attention in political circles, being commended by Robert Walsh, at that time editor of the Philadelphia "National Gazette," who attributed them to the venerable Timothy Pickering.

In 1824, during the somewhat protracted absence of Mr. Allen, he edited the "Herald," superintending the printing at the same time. The struggle of the Greeks for freedom fired his youthful zeal, inasmuch that at one time he seriously contemplated entering the academy at West Point, to qualify himself for a military career. In 1826, his apprenticeship being honorably closed, he became the proprietor and editor of a journal in his native town, called the "Free Press." He toiled hard, generally putting his editorial articles in type without committing them to paper, but the enterprise proved unsuccessful. He then went to Boston, where he worked for a time as a journeyman. In 1827 he became the editor of the "National Philanthropist" in that city, the first journal ever established to advocate the cause of "total abstinence;" but before the end of the year the proprietorship changed, and he was induced, early in 1828, to join a friend in the publication of the "Journal of the Times" at Bennington, Vt. This journal supported John Quincy Adams for the presidency, and was in part devoted to peace, temperance, anti-slavery, and other reforms; but it failed to receive an adequate support. During his residence in Bennington, he produced considerable excitement upon the subject of slavery, not only in that place but throughout the state, in consequence of which there was transmitted to congress an anti-slavery memorial more numerous than any similar paper previously submitted to that body. Benjamin Lundy, an advocate of the gradual abolition of slavery, was then engaged in publishing the "Genius of Universal Emancipation" at Baltimore. He had met Mr. Garrison during the previous year in Boston, and received from him timely assistance in bringing his cause to the notice of the people of that city. Admiring his talents and zeal, and wishing for a coadjutor, he went to Bennington, and engaged Mr. Garrison to join him in the editorship of his journal. On July 4, 1829, Mr. Garrison delivered in Park street church, Boston, at a religious and philanthropic celebration of the day, an address which excited general attention by the boldness and vigor of its assault upon slavery. In the autumn of that year he began his labors in Baltimore as joint editor with Mr. Lundy of the "Genius of Universal Emancipation," and in the first number issued under his supervision he made a distinct avowal of the doctrine of immediate emancipation as the right of the slave and the duty of the master. Mr. Lundy did not concur with him in this doctrine, but as each of them appended his initials to his articles, the difference interposed no barrier to hearty coöperation. The journal, by its bold and uncompromising tone, produced considerable excitement among the supporters of slavery, while Mr. Garrison's denunciations of the colonization society aroused the hostility of some who, upon other grounds, were inclined to sympathize with him. An event soon occurred which resulted in a dissolution of his connection with the paper.

The ship *Francois*, owned by Francis Todd of Newburyport, having taken a cargo of slaves from Baltimore to Louisiana, Mr. Garrison denounced the act as a "domestic piracy," and declared his purpose to "cover with thick infamy" all those implicated therein. Baltimore being then the seat of an extensive domestic traffic in slaves, his denunciation produced a great deal of feeling, and he was in consequence indicted and convicted, in the city court, May term, 1830, for "a gross and malicious libel" against the owner and master of the *Francois*, though it was proved by the custom house records that the number of slaves transported was much greater than he had alleged. He was sentenced to pay a fine of \$50 and costs of court. He was defended by Charles Mitchell, who held a position at the Baltimore bar second only to that of William Wirt. Being unable to discharge the judgment, he was committed to gaol. Mr. Todd, in a civil suit for damages, subsequently obtained a verdict against him for \$1,000; but the judgment, probably on account of his well-known poverty, was never enforced. During his incarceration, he occupied a cell just vacated by a man who had been hanged for murder. He was, however, treated very kindly by the gaoler, and in the daytime had the liberty of the yard. He at once interested himself in the cases of some of his fellow prisoners, and was instrumental in procuring the release of some who were deserving of merciful consideration, by writing petitions in their behalf to the governor. He eagerly embraced the opportunities afforded him for conversing with speculators in slaves, who came to the prison to purchase recaptured slaves, always urging his anti-slavery opinions upon them. His friend Lundy and a few other Quakers were the only persons who visited him to express their sympathy. The press at the North generally condemned his imprisonment as unjust. His letters to different newspapers excited a deep interest, and several sonnets which he inscribed on the walls of his cell were spoken of in influential quarters as worthy of an honorable place in literature. The manumission society of North Carolina protested against his imprisonment as an infraction of the liberty of the press. He remained in gaol 49 days, when Arthur Tappan, a merchant of New York, paid the fine and costs, and he was set at liberty. It subsequently appeared that Mr. Tappan had, in this act, anticipated by a few days the generous purpose of Henry Clay, whose interposition had been invoked by a mutual friend. Daniel Webster, soon after his release, gave him willing audience, and addressed him in words of sympathy and encouragement. His next step was to issue a prospectus for an anti-slavery journal, to be published in Washington; and with a view to excite a deeper interest in his enterprise, he prepared a course of lectures on slavery, which he subsequently delivered in Philadelphia, New York, New Haven, Hartford, and Boston. In Baltimore, his attempts to obtain a hearing were

unsuccessful. Private efforts to procure a suitable place for the delivery of his lectures in Boston having been made in vain, he advertised in one of the daily journals that, if a meeting house or hall were not offered before a certain day, he would address the people on the common. An association of persons calling themselves infidels thereupon proffered him the gratuitous use of a hall under their control, and, no other offer being made, he delivered his lectures in the place thus opened; taking care, at the same time, to avow his faith in Christianity as the power which alone could break the bonds of the slaves. His lectures were attended by large audiences, and awakened in some minds a permanent interest in the anti-slavery cause. His experiences as a lecturer, however, convinced him that Boston rather than Washington was the best location for an anti-slavery journal, and that a revolution of public sentiment at the North must precede emancipation at the South. He accordingly issued the first number of the "Liberator" in Boston, Jan. 1, 1831, taking for his motto: "My country is the world, my countrymen are all mankind;" and declaring, in the face of the almost universal apathy upon the subject of slavery: "I am in earnest, I will not equivocate, I will not excuse, I will not retreat a single inch, and I will be heard." Mr. Isaac Knapp was his partner in the printing and publishing department. As they were without capital or promise of support from any quarter, they were unable to open an office on their own account. The foreman in the office of the "Christian Examiner," being a warm personal friend of Mr. Garrison, generously employed him and his partner as journeymen, taking their labor as compensation in part for the use of his types. Mr. Garrison, after working mechanically in the daytime, spent a large portion of the night in editorial labor. Having issued one number, they waited anxiously to see whether they would find encouragement to proceed. The receipt of \$50 from James Forten, a wealthy colored citizen of Philadelphia, with the names of 25 subscribers, was the first cheering incentive to perseverance, and the journal was issued without interruption from that day. At the end of 8 weeks they opened an office for themselves; but for nearly 2 years their resources were so restricted that they made the office their only domicile. Their bed was made on the floor, and they subsisted upon the humblest fare. The "Liberator" attracted general attention, not only at the North, but at the South. In some quarters it found sympathy, in others it was denounced as fanatical and incendiary. The mayor of Boston, Harrison Gray Otis, having been appealed to by a southern magistrate to suppress it, if possible, by law, wrote in reply that his officers had "ferreted out the paper and its editor, whose office was an obscure hole, his only visible auxiliary a negro boy, his supporters a very few insignificant persons of all colors." Almost every mail, at this period, brought letters threatening Mr. Garrison with assassination if

he did not discontinue his journal; and in Dec. 1831, the legislature of Georgia passed an act, offering a reward of \$5,000 to any person who should arrest, bring to trial, and prosecute to conviction, under the laws of that state, the editor or the publisher. Many of Mr. Garrison's friends, deeming his life seriously imperilled, besought him to arm himself for defence; but, being a non-resistant, he was conscientiously restrained from following their advice. On Jan. 1, 1832, he secured the coöperation of 11 others with himself in organizing the New England (afterward Massachusetts) anti-slavery society, upon the principle of immediate emancipation. This was the parent of those numerous affiliated associations by which the anti-slavery agitation was for many years maintained. In the spring of 1832 he published a work entitled "Thoughts on African Colonization," &c., in which he set forth at length the grounds of his opposition to that scheme. He went immediately afterward to England, as an agent of the New England anti-slavery society, to solicit the coöperation of the people of that country in measures designed to promote emancipation in the United States, and to lay before them his views of the colonization project. He was warmly received by Wilberforce, Brougham, and their associates. In consequence of statements made by Mr. Garrison, Wilberforce and 11 of his most prominent coadjutors issued a protest against the American colonization society, pronouncing its plans delusive, and its influence an obstruction to the abolition of slavery. He also succeeded in inducing Mr. George Thompson, one of the most prominent champions of the anti-slavery cause in Great Britain, to come to the United States as an anti-slavery lecturer. Soon after Mr. Garrison's return, the American anti-slavery society was organized at Philadelphia, upon the principles of which he was the champion. The "Declaration of Sentiments" issued by the association—an elaborate paper, setting forth its principles, aims, and methods—was prepared by him. The agitation previously excited was now greatly intensified, and at length awakened a resistance which manifested itself in a mobocratic spirit, inasmuch that for 2 or 3 years the holding of an anti-slavery meeting almost anywhere in the free states was a signal for riotous demonstrations, imperilling property and life. Mr. Thompson's arrival from England in 1834 inflamed the public mind to such a degree that at length, by the advice of his friends, he was induced to desist from his labors and return to his native land. In Oct. 1835, a meeting of the female anti-slavery society of Boston was riotously broken up by a collection of persons, described in the journals of the day as "gentlemen of property and standing." Mr. Garrison, who went to the meeting to deliver an address, after attempting to conceal himself from the fury of the mob in a carpenter's shop in the rear of the hall, was violently seized, let down by a rope from the window to the ground, and, partly denuded of his clothing, dragged through the streets to the city hall; whence, as

the only means of saving his life, he was taken to gaol by order of the mayor, upon the nominal charge that he was "a disturber of the peace." He was released on the following day, and, under protection of the city authorities, escorted to a place of safety in the country. These scenes of violence were followed by a discussion of the peace question, in which he took an earnest part as a champion of non-resistance; and in 1838 he led the way in the organization of the New England non-resistance society. The "Declaration of Sentiments" issued by that body was prepared by him. About this time, the question of the rights of women as members of the anti-slavery societies began to be mooted, Mr. Garrison contending that, so far as they wished to do so, they should be permitted to vote, serve on committees, and take part in discussion, on equal terms with men. Upon this question there was a division of the American anti-slavery society in 1840; and in the "World's Anti-Slavery Convention," held that year in London, Mr. Garrison, being a delegate from that society, refused to take a seat because the female delegates from the United States were excluded. In 1843 he was chosen president of the society, and has continued to hold the office till this time (1859). He was ever earnestly opposed to the formation of a political party by the abolitionists, from a conviction that such a measure would inevitably corrupt the purity of the movement and postpone the day when emancipation might be secured. He never sought or contemplated the abolition of slavery in the states by congress, or any other branch of the national government, his views as to the powers of that government over the subject being the same that were generally held by statesmen of all parties at the North, as well as by many at the South. His first idea was, that slavery might be abolished by moral influence, with such incidental aid as the national government could constitutionally afford, and without disturbing the union of the states; but upon this point he at length changed his opinions, his observation of the movements of political parties and his reflections upon the provisions of the constitution relating to the subject leading him to the settled conclusion that some of the conditions of compact between the free and the slave states were immoral, and that a dissolution of the Union was necessary to the freedom of the North and the emancipation of the slaves. In 1846 he made his third visit, for anti-slavery purposes, to Great Britain. In 1848 a small volume of his "Sonnets and other Poems" was published; and in 1852 appeared a volume of "Selections" from his "Writings and Speeches" (12mo., Boston.)

GARROTE, a mode of execution practised in Spain and the Spanish colonies. The criminal is seated in a chair or on a stool, and leans his head back against a support prepared for it. An iron collar closely encircles the throat. The executioner quickly turns a screw, the point of which penetrates the spinal marrow where it

unites with the brain and causes instantaneous death. Formerly the garrote was merely a cord put round the neck and suddenly tightened by the twisting of a stick inserted between the cord and the back of the prisoner's neck. Hence the name of this mode of execution, *garrote* in Spanish signifying stick. Its origin may probably be traced through the Moors or Arabs to the oriental punishment of the bowstring, which in its primitive style it exactly resembled. Afterward an iron collar was used by which the criminal was suddenly strangled. The piercing of the spinal marrow is a later improvement.

GARTER, ORDER OF THE, the highest British order of knighthood, and one of the oldest and most illustrious of the military orders of knighthood in Europe, commonly said to have been instituted by Edward III. of England about 1350. The precise date of its foundation has been much disputed. In Rastel's "Chronicle" it is stated that the order was devised in 1192 by Richard I., who made 26 of his knights wear blue thongs of leather around their legs in a battle fought with the Saracens on St. George's day. In the accounts of the great wardrobe the garters of the order are first mentioned in 1348. Most writers agree that its institution dates from a tournament at Windsor, to which Edward invited the most illustrious knights. It was founded in honor of the Trinity, the Virgin Mary, St. George, and St. Edward the Confessor; and St. George, who was already the tutelary saint of England, was considered its especial patron and protector. An ancient tradition connects the emblem of the order with the story popularly told of Edward and the countess of Salisbury. When she happened at a ball to drop her garter, the king took it up and presented it to her, at the same time exclaiming, with reference to those who smiled at the action: *Honi soit qui mal y pense* ("Evil to him who evil thinks"). Edward added "that shortly they should see that garter advanced to so high an honor and renown as to account themselves happy to wear it." This is the common account of the origin of the emblem and motto, though others suppose them to have had reference to Edward's claim to the crown of France and to the wars in that kingdom. The original dress of knights of the garter was a blue mantle, tunic, and capuchin, cut in the fashion of the time, and all embroidered with garters of blue silk and gold, the largest of which, bearing the device, was on the left shoulder of the mantle. It was remodelled by Henry VIII., and changed for the last time by Charles II. It now consists of the garter of dark blue velvet, edged with gold and bearing the motto in golden letters, and worn on the left leg below the knee; the mantle of blue velvet, lined with white taffety, and having on the left breast the star, which is the cross of St. George irradiated with beams of silver, and encircled with the garter; the hood, of crimson velvet; the surcoat, also of crimson velvet, lined with white taffety; the hat, of black velvet, lined with white taffety, and bear-

ing an ostrich and heron plume; the collar, composed of 26 pieces of gold, each in the form of a garter, and having the ground enamelled blue; the figure of St. George on horseback, encountering the dragon, appended to the collar; and the lesser St. George, enamelled on gold and set with diamonds, suspended by a dark blue ribbon over the left shoulder. The number of knights companions was originally 25 beside the sovereign, who nominates the other knights. The queen and wives of the knights at first shared the honors of the fraternity, were styled *dames de la fraternité de St. George*, and wore robes and hoods adorned with the garter; and an attempt to revive this ancient usage was made in the reign of Charles I. The original number of knights remained unchanged till 1786, when a statute was passed making it 26 exclusive of princes of the royal family and of illustrious foreigners on whom the honor might be conferred. By a statute of 1805 the order is to consist of the sovereign and 25 knights companions, together with such lineal descendants of George II. as may be elected. But the prince of Wales, as a constituent part of the original institution, is counted among the 25 companions. By special statutes, proclaimed at different times, foreign sovereigns and extra knights have been admitted, the latter of whom on the occurrence of vacancies always become part of the 25. The whole number at present is 41, 26 of whom are knights companions, Lord Derby having been made an extra knight after the close of his ministry in 1859. The officers of the order are a prelate, who is always the bishop of Winchester; a chancellor, formerly the bishop of Salisbury, but since 1887 the bishop of Oxford (Windsor, which is in Berkshire, having been then transferred to that diocese); a registrar, the dean of Windsor; a garter principal king-at-arms, who carries the rod and sceptre at the feast of St. George, notifies the election of new knights, and is chief of the heralds; and the usher of the black rod. The chapter meets on St. George's day (April 28) in St. George's chapel, Windsor, where the installations take place, and the banners of the knights are suspended.

GARTH, SIR SAMUEL, an English physician and poet, born in Yorkshire, died in London, Jan. 18, 1718. He studied medicine at Cambridge, and settling in London in 1693, soon secured an extensive practice, and became noted for his classical taste, liberality, and social habits. A quarrel had existed for some years between the physicians who advocated, and the apothecaries who opposed the establishment of a free dispensary for the poor. Garth sided with the former, and wrote in their support the "Dispensary," a satirical poem in imitation of Boileau's *Lutrin*. It was published in 1699, passed through 3 editions in a few months, and reached the 9th in 1706, having been modified and improved in each. In the heroic couplet afterward so effectively employed by Pope, and with the supernatural machinery of the ancient

epic, its dry theme is well sustained through 1,000 lines; but it is now regarded only as a literary curiosity. Garth was the leading whig physician of the time, was a member of the Kit-cat club, and the intimate associate of Addison (for whose "Cato" he wrote an epilogue), Dryden, Congreve, Swift, Pope, &c. He wrote several short poems, and superintended a translation of Ovid's "Metamorphoses" (1717), to which Dryden, Addison, Gay, and many others contributed. He translated the 14th and part of the 15th book, and wrote the preface, in which he recommends the moral purpose of the work. He was knighted by George I. in 1714.

GÄRTNER, JOSEPH, a German botanist, born in Calw, Würtemberg, March 22, 1732, died July 13, 1791. He studied theology, jurisprudence, and the natural sciences at Tübingen and at Göttingen, travelled in Italy, France, England, and Holland, became professor of anatomy at Tübingen in 1761, and of botany at St. Petersburg in 1768. He returned to Calw after 2 years, where he devoted himself for the remainder of his life to the study of botany, making several long journeys for that purpose. His labors mark an era in the history of this science, since, while other botanists had proposed only the different characteristics of the flower as a basis for classification, he was the first to observe that plants are naturally divided into classes by the general plan and features of their construction. His principal work is *De Fructibus et Seminibus Plantarum* (Stuttgart, 1789-'91).

GAS (Sax. *gast*, Dutch *geest*, Ger. *Geist*, spirit), a generic term designating any elastic fluid which is neither liquefied nor solidified at ordinary temperatures and pressure. Van Helmont introduced the name, first applying it to carbonic acid generated by fermentation, which he described as a non-coagulable spirit. Boyle afterward made use of the term artificial air, and recognized different varieties of the elastic fluids. In 1757 the nature of the so called fixed air or carbonic acid was determined by Dr. Black, and the composition of other gaseous bodies was soon after investigated by the chemists, with whom this became a favorite department of research. The principal gases are described in this work under their respective names, and the physical properties of elastic fluids are treated in the article ATMOSPHERE.—In ordinary use, by the term gas is understood that mixture of inflammable elastic fluids obtained from bituminous coal or other carbonaceous substances for illuminating purposes. A natural product of similar character has been known in various countries from remote times, issuing from crevices in the earth, and appears to be the result of substances of organic origin slowly undergoing decomposition. Though the supplies of the gas appear to be inexhaustible, inasmuch as it has continued to issue at the same localities for many centuries, its source is not always in beds of coal, but frequently in formations below the coal measures. The most celebrated natural fountains of this kind are in the ter-

tiary strata on the borders of the Caspian sea, described in the article BAKOO. In the western part of the state of New York they issue from the slates and sandstones of the Portage group, and the gas is so abundant and pure that it is collected in gasometers and conveyed in pipes to be used for lighting villages. The town of Fredonia has been thus illuminated for many years, and also the lighthouse at Portland harbor on Lake Erie. The Chinese have long made use of the jets of gas they struck in their salt wells, applying it as fuel in evaporating the brine, and as an illuminating agent for their buildings and streets. Instances have been noticed in the article COAL of its bursting out in penetrating beds of this material. It has also issued in copious streams from beneath great bogs when these were pierced and the boring was continued through beds of marl and sand which underlaid them. This was observed at Chatmoss, on the line of the railway between Manchester and Liverpool, in Dec. 1851. The gas rose rapidly through a 10 or 12-inch pipe sunk in the ground over the hole which tapped its source, and issuing from this at the height of 86 feet was then ignited, and burned with a yellowish flame extending upward some 8 or 9 feet. Numerous other instances of such phenomena in various countries might be referred to. The natural inflammable gas is known by various names, as light carburetted hydrogen, fire damp, and marsh gas, the last name having reference to its bubbling up through the waters covering marshy places. It possesses less carbon than the other variety of carburetted hydrogen, called olefant gas, which is obtained in mixture with it in the process of the destructive distillation of bituminous coal, and which, with the vapors of other hydrocarbons rich in carbon, gives to the artificial product a much higher illuminating power than that of the natural gas. The peculiar qualities of this mixture will be considered after tracing out the history of the application of gas to illuminating purposes, and noticing the materials employed. The practicability of collecting the gas expelled from coal by subjecting this to heat appears to have been first discovered by Dr. Clayton, rector of Crofton, Wakefield, Yorkshire. The account of his experiments is preserved in a letter to the Hon. Robert Boyle, dated May 12, 1688, and published in the "Transactions of the Royal Society," 1789. He distilled some coal in a retort, and accidentally discovered the inflammability of the "spirit" which issued forth, bursting through the lute. He collected this spirit in bladders, which he kept, and amused his friends by puncturing them, and burning the invisible fluid as it escaped through the aperture. Dr. Hales in his work on "Vegetable Statics," 1726, describes a similar experiment he had made, and his obtaining 180 cubic inches of inflammable air from 158 grains of Newcastle coal. In 1786 Lord Dundonald of Scotland engaged in distilling coal, chiefly it appears from

the tar, and the next year took out a patent for the process. He constructed apparatus for burning the gas, merely, however, as a curiosity, and his workmen employed the waste gas for giving them light. The first experiments for the direct purpose of introducing gas as an illuminating agent were made in 1792 by Mr. Murdoch, then residing at Redruth in Cornwall. In 1797 he brought his operations into public notice, and the next year fitted up an apparatus for lighting part of the manufacturing establishment of Boulton and Watt near Birmingham, with which he had become connected. A Frenchman named Le Bon was engaged about the same time in similar experiments in France; and by means of gas which he obtained from wood he succeeded in lighting and warming his house. In 1803-'4 the lyceum theatre in London was lighted with gas under the direction of Mr. Winsor, one of the earliest advocates for its general introduction. In 1804-'5 Mr. Murdoch constructed the largest apparatus hitherto made, and lighted the mills of Messrs. Phillips and Lee at Manchester, distributing an amount of light through the building equal to that of nearly 8,000 candles. In 1813 Westminster bridge was lighted with gas, and the next year the streets also of this part of London. The manufacture was greatly improved by the researches of Dr. Henry the chemist, and by the apparatus, including the wet gas-meter, invented by Mr. Clegg, an engineer employed by Boulton and Watt. Gas from refuse oily and fatty matters was first prepared on a large scale by Mr. Taylor, who obtained a patent for the process in 1815. The manufacture was conducted at the gas works in London, Paris, and other cities; but though the gas was of superior quality, more dense than that from coal and more highly carburetted, the cost of the raw material was too great in comparison with that of coal for the business to prosper. It has of late years been successfully introduced in the United States, principally with small apparatus for single buildings, and with the employment of the cheap rosin oil. This is converted into gas, as it is dropped upon a heated surface, and, without the necessity of the purifying apparatus required for coal gas, it is conducted into the gasometer for distribution as it is required. It may be regarded as one of the most perfect, simple, and economical methods of obtaining a beautiful artificial light. Rosin itself has also been applied directly by an apparatus in which it was melted, and in this state allowed to enter the heated retort for conversion into gas. The process, however, was not an economical one. Animal matters distilled for the production of bone black evolve inflammable gases, and these have been applied to purposes of illumination by Seguin. Gas has been made from wood for some time past at the Market street bridge works in Philadelphia, and 6 retorts have been kept in use. In Germany wood gas has been employed to some extent for lighting towns. The wood, well

dried, is introduced into red-hot retorts, and the gas which is immediately given off is conveyed through the usual apparatus for purifying coal gas. Tar is obtained in large quantity, and the charcoal, which is finally removed from the retort and quenched with wet sand, is more valuable than the coke residue of the distillation of bituminous coal. In Munich retorts are used holding 90 lbs. of wood. They are freshly charged every hour and a half. The operation is conducted with great facility, and the retorts are not injured by the fire as in the coal gas manufacture. Wood gas is usually considered inferior to coal gas, from deficiency of carbon, unless passed through some liquid hydrocarbon, as naphtha, benzole, oil of turpentine, or over incandescent charcoal. Samples of gas from old field pine and from smaller second growth oak have been found, by the analyses of Dr. Wollcott Gibbs and Dr. F. A. Genth, to present the following composition:

	Gas from pine.	Gas from oak.
Hydrogen.....	82.71	80.44
Light carburetted hydrogen.....	21.50	83.13
Olefant gas and hydrocarbon vapors.....	10.57	6.46
Carbonic oxide.....	27.11	26.11
Carbonic acid.....	4.90	0.48
Oxygen.....	0.66	none
Nitrogen.....	2.55	8.89

—In Philadelphia works were put in operation in 1858 designed for making gas from water, or at least obtaining from this its hydrogen, and, while in the nascent state, introducing it to carbon also in the act of separating from its combination with other substances. Steam at 20 lbs. pressure is passed through a round retort filled with incandescent wood coal, by which it is said to be decomposed and to yield 56 per cent. of hydrogen. This is immediately delivered into another red-hot retort, in which rosin or rosin oil is employed for making gas by dropping it in upon the heated surface. Illuminating gas is reported to be made by this method at the extremely low price of 48 cents per 1,000 feet, and by one report even at 36 cents; but there appears to be a difficulty in furnishing the proportion of hydrogen required, and instead of the operation regulating itself, it is found necessary to keep a man most of the time attending to the two stopcocks. Practical difficulties are experienced by the deposition of free carbon in the form of soot upon the inside of the retorts, and carbonic acid and carbonic oxide are also generated. The vapors of benzole have been advantageously employed for illumination by passing through the liquid a current of common air or of steam, which takes up and carries along the vapor, the properties of which it modifies according to the proportion of air or steam employed. (See BENZOLE.) Peat has been successfully distilled upon a large scale for the production of illuminating gas; and another material profitably employed for the same purpose at Rheims is the refuse soap water in which woollen stuffs had been worked to free them

from greasy matters. This water is bought up and brought to the gas works, and being treated with sulphuric acid the fatty matters rise to the surface, and are collected, and finally distilled.—Coal gas, as before remarked, is a mixture of several gases and vapors possessing very different illuminating powers; their relative proportions in different specimens of the mixture are also very variable. The chief ingredient is the light carburetted hydrogen, which has little or no illuminating power, and may be compared to nitrogen in the atmosphere in considering the adaptation of this æriiform mixture to respiration, while the active ingredient in the air or breath (oxygen) finds its counterpart in the light-giving olefiant gas and the rich hydrocarbons of unknown number, which add their vapors to increase the illumination. Light carburetted hydrogen, when free from carbonic acid, nitrogen, and other foreign matters such as usually accompany it, consists of carbon 75 and hydrogen 25 parts in 100. Its symbol is sometimes given as CH_2 , and sometimes C_2H_4 , the proportions of the elements in these being the same; but it is supposed by some chemists that 1 volume of the compound consists of 1 equal volume of carbon vapor and 2 of hydrogen, and by others of 2 of the former and 4 of the latter condensed into the same bulk. Hydrogen and carbonic oxide (CO) are also present in coal gas, and, like the carburetted hydrogen, act the part of diluents. Olefiant gas consists of 86 parts of carbon and 14 of hydrogen, and is expressed by the formula C_2H_2 , or, as adopted by some, C_4H_4 . The same volume contains double the quantity of carbon that is found in light carburetted hydrogen. Its specific gravity is 0.985, while that of the last-named gas is 0.559, air being 1.000. Other hydrocarbons which yield vapors to the gas are all represented by the same general formula C_xH_y , their difference of character resulting from the different degree of contraction which the volumes of the elements undergo in combining. This appears to constitute the only difference between substances, some of which are exhibited in gaseous, some in fluid, and some in solid form; and it also accounts for the remarkable instability they all display. Some of these hydrocarbons, the vapors of which are found in coal gas, contain double the amount of carbon in a given volume that belongs to olefiant gas, and consequently possess twice the illuminating power, this being proportional to the amount of carbon, as the life-supporting power of the atmosphere is proportional to the quantity of oxygen present. But neither of these active constituents can be added indefinitely to illuminating gas or to the air without defeating the useful effect. Too much carbon involves imperfect combustion, and the richer vapors are more advantageously consumed when dispersed through a body of comparatively inactive gases. The peculiar action of those which perform this office of diluents deserves attention. Carburetted hydrogen in combustion consumes twice its volume of

oxygen, generates its own bulk of carbonic acid, and one cubic foot produces heat sufficient to raise the temperature in a room of the capacity of 2,500 cubic feet from 60° to 80.8° . Carbonic oxide consumes half its bulk of oxygen, generating its own bulk of carbonic acid, with heat sufficient from the combustion of one cubic foot to raise the temperature of the above amount of air from 60° to 66.6° . Hydrogen consumes half its bulk of oxygen, generates no carbonic acid, and one cubic foot produces heat sufficient to raise the temperature of the given amount of air from 60° to 66.4° . To produce therefore the least heat with the least vitiation of the air of the room, hydrogen is the preferable diluent. In what is known as White's hydrocarbon method of gas-making, it was supposed that the production of the most perfect mixture was approximated. The illuminating constituents are generated in as concentrated a form as possible in one retort, and the diluents, consisting principally of hydrogen, free from light carburetted hydrogen, in another. The diluents are conducted so rapidly through the retort in which the production of the illuminating gases is going on, that they are swept forward before they can be decomposed by the action of the red-hot surfaces of the retort. In this way, as stated by Dr. E. Frankland in communicating these facts to the royal institution, London, coal is frequently made to produce an increase of 200 to 300 per cent. over the usual quantity of gas, and this of 50 to 100 per cent. greater illuminating power. For some reason, however, probably the skill and care required to conduct the process, the operation has not been successfully adopted.—The quantity and quality of gas obtained from bituminous coal vary greatly with the character of the coal itself, and also with the manner in which the distillation is conducted. A poor kind of coal will not make good gas; and a large yield may be no recommendation of the process employed. Cannel is the variety of coal preferred both for the quantity and quality of the gas it affords. It is exported from England to the United States for this use, and also to Berlin. Some of the mines in Virginia and the western states furnish excellent varieties of this fuel. Where it cannot be had, the richest caking coals are used, and are probably more employed than the cannel. A ton (2,240 lbs.) of good cannel coal yields in large operations about 10,000 cubic feet of gas; and 9,000 to 9,500 feet is considered an average product from Newcastle and other good caking coals. A pound of good coal may be regarded as yielding 4 to $4\frac{1}{2}$ cubic feet of gas. Some still more volatile coals have been found even better adapted for gas manufacture than the cannels before known. Such are the Boghead cannel, found between Edinburgh and Glasgow, which is said to produce 13,500 feet of gas per ton, of specific gravity 0.775, and the so called Albert coal of New Brunswick. (See COAL.) In submitting the coal to the action of heat in close

retorts, which may be of cast iron or of clay, the first substances evolved are steam and atmospheric air. The former is an objectionable product for several reasons, and the coal should consequently be kept as free as possible from moisture before it is used. The conversion of water into steam absorbs a portion of heat, and serves to keep down the temperature in the retort, causing the evolution of tarry matters, which at a higher temperature would have been converted into gas. The steam also is liable to be decomposed in coming in contact with portions of the fuel heated to redness, and its oxygen thus unites with proportionate quantities of carbon, producing carbonic acid and carbonic oxide, and thus robs the coal of a part of its chief gas-producing elements. The hydrogen set free passes over uncombined with carbon. While the retorts are at a low red heat the ingredients of the coal tend to form chiefly tarry matters, and with them come over aqueous and ammoniacal vapors and sulphurous acid. The ammoniacal product derives its nitrogen from the atmospheric air contained in the retorts, and as it comes over unites with the sulphurous acid. A portion of the sulphur of the pyrites present in the coal unites with hydrogen, forming the gas sulphuretted hydrogen, and a portion uniting with carbon forms the very injurious product sulphuret of carbon. The numerous oily compounds, exceedingly rich in carbon, are also produced, which remain in part with the tar, and in the form of vapor also mix with the carburetted hydrogen and olefiant gas, which are at the same time evolved, adding largely to the illuminating property of the mixture. At a full red heat the gaseous mixture sought for is almost exclusively produced; and it is therefore an object to bring the contents of the retorts as rapidly as possible into this condition to avoid their being wasted by their elements forming comparatively useless compounds. The retorts are for this reason not allowed to cool when discharged of the coke residuum and recharged with fresh coal. In the old practice of 8-hour charges it was estimated that in the first hour of the operation 20 per cent. of the whole product of illuminating gas was obtained, and in each succeeding hour the following proportion: 2d, 15 per cent.; 3d, 14; 4th, nearly 13; 5th, 12; 6th, 10; 7th, 9; 8th, 8. The gas at first has but little illuminating power. It is the best in the early part of the process, while the coal is becoming thoroughly heated, its specific gravity then being 0.650, after which it gradually falls to about 0.845 at the close of the operation. At 8 different stages of the distillation continued for 10 hours the mixture has been found to be in 100 measures as follows: 1st, carburetted hydrogen 82.5, olefiant gas 18, carbonic oxide 8.2, nitrogen 1.8—sp. gr. 0.650; 2d, at 5 hours, carburetted hydrogen 56, olefiant gas 7, carbonic oxide 11, hydrogen 21.8, nitrogen 4.7—sp. gr. 0.5; and at the close of the operation olefiant gas had disappeared, carburetted hydro-

gen was 20, carbonic oxide 10, hydrogen 60, nitrogen 10—sp. gr. 0.845. Though the presence of any of these ingredients is not regarded as impairing the technical purity of the gas, its quality for illuminating purposes is greatly affected by the different proportions in which they are found; and by continuing the operation too far it is obvious that the proportion of non-illuminating compounds rapidly increases. Sulphuretted hydrogen is especially apt to make its appearance, and become intermixed in the last stage of the process, seriously affecting the purity of the mixture. Other substances which contaminate it are the vapors of water and ammonia, formed in the first part of the operation, and which should be condensed and separated in the tar receiver, and also carbonic acid and sulphurous acid gas. At high temperatures the retorts become coated with a dense carbon of excessive hardness, which is supposed to be deposited from gaseous carbon separated from light carburetted hydrogen, hydrocarbon vapors, or from olefiant gas, as these are decomposed in passing over very hot surfaces. The latter gas may be made to yield up a portion of its carbon in this form by conducting it through red-hot tubes, and the volatile hydrocarbons are known to be similarly affected. High temperature is therefore injurious from its tendency to decompose the most valuable products of the distillation, and reduce the substances to their elementary condition or simple combinations nearly approaching it. The methods in use, however, for effecting the decomposition of carbonaceous compounds, which produce illuminating gas, do not admit of the complete regulation of the temperature which a perfect operation would require; and there is hence a necessary waste of gas in the manufacture and uncertainty as to its exact composition. The duration of the process is now generally reduced to from 4 to 6 hours, depending upon the kind of coal and size of the retorts, and the richest gases are evolved during the first hour. In Scotland the rich cannels are sometimes carbonized in 8 hours. By practice and careful attention to the qualities of the materials employed, manufacturers succeed in producing at the same works an article not varying greatly in composition; but the gas of different establishments is found to be of very different qualities. Its value is estimated by referring it to some standard with which the illuminating power of a given quantity is compared by actual trial. Five cubic feet of gas are commonly consumed in an hour by an Argand burner, and the light is compared by means of suitable instruments with that of spermaceti candles, each burning 120 grains in an hour. The gas of the London works varies with the coals employed, from an illuminating power of 11.5 to 18 candles, the best results being with varieties of cannel, which also commonly afford a few hundred feet more of gas per ton. The range at these works in variable amount of product rarely exceeds 1,000 cubic

feet to the ton of coal, or about one-tenth of the whole product. The greatest specific gravity (about 0.90) is that of cannel coal, producing the greatest quantity of gas and of highest illuminating power. This property therefore may be conveniently appealed to as an auxiliary test of the comparative qualities of different gases. The presence of impure heavy gases, or even of atmospheric air, would, however, by increasing the figures, lead to a false estimation of the value of the gas, unless other tests were resorted to. These may be organic analysis, determination of carbon by the amount of carbonic acid produced by explosion with oxygen, or the direct determination of the proportion of olefiant gas and hydrocarbon vapors present in the mixture by the condensation produced in it by the introduction of chlorine, bromine, or sulphuric acid—substances which have the property of absorbing and forming fluid compounds with those highly carburetted bodies on which the value of coal gas depends. The gas of the Liverpool works is far superior to that of London; it is sometimes found equal to 23 candles. The New York companies very seldom make 20 candle gas, but their product is usually about 16 candle. The Manhattan company use from $\frac{1}{2}$ to $\frac{3}{4}$ cannel coal. The Boston company uses about $\frac{1}{4}$ cannel. The following table presents the production in gas of the best foreign coals, with the specific gravity and weight of the gas to the ton of coal. The authority

for Nos. 1 and 2 is a parliamentary return; 3 and 12, Dr. Fyfe; 4, 5, 6, the British "Journal of Gas Lighting;" 7, 10, 11, 19, 20, Mr. Clegg; 8, 9, 14, 15, 16, Mr. Joseph Hedley; 13, John Kay, of the Dundee gas works; 17, 18, 21, Mr. J. Evans.

Description of coal.	Cubic ft. of gas per ton.	Specific gravity of the gas.	Wt. in lbs. av. per ton of coal.
NEWCASTLE COALS.			
1. Leeds coal	6,500	.580	268
2. Derbyshire soft coal	7,000	.448	240
3. English caking coal	8,000	.420	257
4. Washington coal	10,000	.480	330
5. Dean's Primrose	10,500	.480	347
6. Pelton	11,000	.480	368
7. Felling main	11,200	.410	361
8. Blenkinsop, Carlisle	11,200	.581	447
9. Newcastle coal	11,648	.675	428
10. Russell's Wallsend	12,000	.418	384
11. Pelaw main	12,400	.420	399
CANNEL COALS.			
12. Scotch parrot	9,500	.640	466
13. Ramsey's Newcastle cannel	9,333	.598	437
14. Washington cannel	10,500	.500	408
15. Leamhagow cannel	11,212	.787	638
16. Pelton cannel	11,500	.680	459
17. Arncliffe cannel	12,600	.628	606
18. Knightswood cannel	12,200	.550	558
19. Scotch cannel	14,000	.580	623
20. Wigan cannel	14,458	.640	708
21. Boghead cannel	15,000	.759	866

The following table by Mr. Wright presents in another form the proportions of the other ingredients also which are obtained in the distillation of coal:

Ingredients (lbs. per ton).	Leamhagow cannel.		Ramsey's Newcastle cannel.	Derbyshire deep main.	Wemyss's cannel.		Wigan cannel.
	Ex. 1.	Ex. 2.			Ex. 1.	Ex. 2.	
Coke	1091.0	1064.0	1485.00	1885	1194.5	1,183	1296
Gas	458.0	458.5	410.00	800	551.4	523	388

Total	2240.0	2240.0	2240.00	2240	2240.0	2240	2240
Cubic feet of gas	11,681	9,878	9,016	9,400	10,976	10,192	9,408
Specific gravity	0.540	0.650	0.604	0.424	0.670	0.691	0.478
Illuminating power, gas of sp. gr. 0.861 being 1	2.88	2.0	0.8	2.47	...	1.5

The product of coke is usually estimated at about 2 bushels to the cwt. of coal; and about $\frac{1}{2}$ of the whole product is consumed for heating the retorts. The coal tar is also in part consumed for the same purpose; but its principal use has been for the preparation of a paint, which is much employed for coating iron work exposed to the weather. Of late it is largely distilled to obtain from it coal naphtha and coal oil. The pitch which remains as a residuum is used to pay the bottoms of vessels, &c. —**GAS MANUFACTURE.** Supplies of gas are furnished to cities and towns by chartered companies, which provide extensive manufactories, and lay under the streets the cast iron pipes for conveying the gas to any distance required. The works, varying in extent according to the demand for their product, are constructed upon the same general plan. In selecting a suitable location for them, the chief objects sought for are convenience in supplying the materials required,

and a spot where the products of the operations escaping from the works can do no serious injury to neighboring property. The process, as carried on in these works, is analogous to the combustion of candles for the production of light. The capillary tubes of the wick, in which the liquefied wax or tallow is decomposed by heat and produces the inflammable gaseous matters, correspond to the retorts in which the coal is decomposed. The long iron pipes are extensions of the tubes of the wick, at the extremities of which the gases are ignited. In the one case, however, the combustion of the gases as produced affords the heat for effecting the decomposition of fresh portions of the material that generates them; while in the other the combustion is at distant points, and a separate fire is required to effect the decomposition. In gas works the first objects of interest are the retorts. These are commonly made of cast iron, but others of fire clay are extensively used in

England, and by many are considered decidedly superior to those of metal.* The iron retorts are made of various forms—plain cylinders 7 feet long and 1 foot diameter, also of oval cross section; and again of the same modified by the bottom being bent in toward the centre, giving to the cross section a kidney or ear shape; but the last, which were formerly in high favor, are now entirely out of use. The kind generally preferred at present is the so called D-shaped retort, its cross section having the shape of this letter, with the flat side for the bottom. They are from 7 to 9 feet in length, from 1 to 2 feet in width, and from 12 to 15 inches in height. Many works use what are called "through retorts," which are from 16 to 18 feet in length. These are charged at each end. Experienced engineers regard them as the most economical. Retorts are set in groups of 3 to 13 in each furnace. In large establishments the furnaces are double stacks, 2 single retorts placed end to end or one through retort reaching through, so that the neck or mouthpiece of each projects through the exterior wall; the fire places under the retorts also open out on either side, and the flues from all of them unite in one along the central line of the stack. The retorts are set in the brick work in 2 or 3 horizontal rows, 5 for each furnace with a fire under each of the 2 or 3 retorts of the lower row. The flame from the fires can pass among them all before escaping by the flue. The furnaces succeed each other in the same stack through the length of a large building, the retorts in large establishments numbering many hundred, of which all may be kept in operation in the winter season, and part only in the summer. At the great central gas works in London a new form and arrangement of retorts have been tried within a few years, by which it was thought great economy in consumption of fuel for distilling the coal was effected, together with increased production of gas and other advantages. But after the most flattering reports, the trial does not seem to have been satisfactory, as the company are said to have returned to the old plan. Thirteen retorts were arranged over one furnace fire, set in 2 series, the upper of 6 retorts, 18 feet in length, made of fire clay, only their necks of cast iron pro-

jecting beyond the brick work. The lower set were of iron 19½ feet long, going like those above completely through the stack, and like them they were charged and discharged at both ends. They were heated by the descending current of flame, which had first been led around the earthen retorts. These bear a higher heat, and they also retain it much better, than the iron retorts; they were charged every 4 hours, while the others were charged every 6 hours. The average yield of each retort was 18,500 feet of gas per day. By this arrangement a large number of retorts of great capacity is concentrated in comparatively little room. Clay retorts accumulate little of the solid carbon, which is apt to form a hard lining in the iron ones, requiring them to be frequently cleaned out with great labor. That which collects in the former is easily removed in flakes with a bar on leaving them open at both ends so that a current of air can pass through. An iron retort is estimated to last through the production of 700,000 feet of gas; 6 times this amount has been obtained from a "through" clay retort. All forms of retorts are provided with a mouthpiece, commonly of the same size with the body, to which it is attached by bolts, if the parts are not both in the same piece. This mouthpiece projects in front of the brick work, and the pipe called the stand pipe, usually about 4 inches in diameter, for conveying off the gases, enters through its upper side, and rises 4 or 5 feet up the front of the brick work, then bending back passes down by what is called the dip pipe into the large horizontal pipe laid on the top of the brick work, which is called the hydraulic main, and receives the products from all the retorts in the furnaces beneath it. The retorts are charged with coal by means of a long semi-cylindrical scoop of sheet iron, which being filled, and the old charge being raked out, is pushed into the red-hot retort; by means of the handle it is twisted over so as to empty itself, and is then withdrawn. A charge of 120 to 200 lbs. of coal, about half filling a single retort, is thus introduced at once. Before much gas can escape, the cast iron cover, coated with suitable luting, is brought into place and screwed fast. In discharging a retort the cover is first loosened, and the gas which escapes is ignited. By this means an explosion is avoided, which would be likely to occur if the interior were suddenly exposed to the atmosphere. The coke, as it is withdrawn, bringing with it a large amount of heat, is sometimes used in the furnaces at once with great economy, no time being allowed for the heat to escape. The hydraulic main is about half filled with water or fluid tar, which is made to retain its level by a discharge pipe suitably placed. Into this the dip pipes penetrate about 3 inches; and the aeriform fluids, pressed forward from the retorts, readily pass up through the denser fluid to the reservoir above, but are prevented by it from turning back through the pipes when the flow from the retorts is interrupted. The hydraulic main is a very strong pipe of cast or

* A late paper on clay retorts by Mr. J. Church, read to the London Institution of civil engineers, presents the following facts relating to the comparative quantities of gas made by the two kinds of retorts of the  form, of 15 inches by 18 inches in section, and 7½ feet in length. Iron retorts lasting 865 days, and working off 1½ cwt. of coal for each charge, effected the carbonization of 2,190 cwt. of coal, which at 3,000 cubic feet of gas per ton gave a total quantity of 985,500 cubic feet of gas per retort; while the clay retorts lasted 912 days, carbonized 5,478 cwt. of coal, which at 3,000 cubic feet of gas per ton gave 2,482,000 cubic feet of gas per retort. It will thus be seen that the clay retorts yielded a greater quantity of gas from the same weight of coal than the iron retorts; but the specific gravity of the gas thus made was less, and its illuminating power was diminished in consequence of the increased temperature of the clay retorts, which caused the last portions of the gas to be decomposed. Clay retorts in large establishments are best worked with the addition of an exhaustor. The pressure is thus reduced, and the gas not escaping through the pores, the quantity is increased about 200 cubic feet per ton of coal. In small works, the exhaustor would not save the expense of its introduction, requiring as it does steam power to work it.

of boiler plate iron, often a foot and a half in diameter, placed exactly level, and extending the whole length of the furnace stacks. It serves to collect a large portion of the tar and ammonia; but a part is kept by the heat in the state of vapor, and is carried along with the gas. To separate this, the mixture is cooled by passing it through a series of tall condensing pipes of iron placed in the open air, and sometimes kept cool by water made to trickle down their outside surface. The gas goes up one and down another in succession. At the bottom of each pair a pipe communicating with a cistern in the ground conveys to this the tar and ammonia which separate from the gas. From the condensers the gas in some works passes into the bottom of a large tower nearly filled with paving stones or coke, and having a contrivance at the top for sprinkling a fine shower of water in the space above the contents. After rising up into this space, the gas, deprived of still more tar and ammonia, passes down by a pipe which leads under the tower and terminates in the bottom of another similar one close by, discharging the gas among the stones or coke. From the top of this it is conveyed down again by a large pipe which passes under ground to the next apparatus. The towers are called scrubbers; the sprinklers at the top consist of hollow cross-arms perforated with small holes and kept revolving by steam power. The passage of the gas through different parts of the apparatus is continually subjected to increased resistance, which is all turned back upon the retorts. The weight of the gas holders at the end of the series adds largely to this pressure. The effect of it is found to be a proportional increase of the carbonaceous deposit in the retorts; and this causes them to burn out rapidly, and moreover is produced, it is believed, at the expense of the most valuable light-producing vapors. In the use of clay retorts the gas is even forced by the pressure through the porous material. The gas obtained is also of poorer quality by reason of the pressure; and the materials tend to produce a large proportion of tar. To obviate these injurious effects an apparatus has been introduced within a few years, called the exhauster, which, placed next to the scrubber, pumps up the gas and forces it along. A highly approved form in use at Liverpool is an oscillating machine of the plan of the *ventilateur du Hartz*, described at the end of the article *BLOWING MACHINES*, to which reference may be made for its description. In New York a revolving exhauster is employed on the plan of that of Jones of Birmingham or Beales of London. The next operation is to separate from the gas the mixed sulphuretted hydrogen and carbonic acid; also any ammonia that may be present (if the scrubber apparatus has not been used), combined with either carbonic, hydrochloric, sulphurous, or sulphuric acids. For this purpose the mixture is passed into either the wet or dry lime purifier. In the former it is distributed under a surface of lime water, or milk

of lime, so as to bubble up through the liquid, which at the same time is stirred by a rapidly revolving arm. Provision is made in some machines for drawing off the old liquid and supplying fresh portions, as the lime is exhausted by combining with the chlorine and hydrosulphuric acids. But a better method is to employ two pairs of machines, and, as the lime in one becomes spent, replace them with the other. The proportion of lime required varies of course with that of the sulphuretted hydrogen and carbonic acid present. As a general allowance, a bushel of quick lime mixed with 48 gallons of water should, if properly applied, purify 10,000 cubic feet of gas. The product should be frequently tested to determine its purity. This is done by presenting a piece of paper moistened with solution of acetate of lead to a jet of the escaping gas. If it becomes discolored at all, the gas is impure. The dry lime purifier consists of an iron box, until recently about 6 feet in length, 5 in breadth, and 8 in depth, but now sometimes 25 feet square, arranged with several shelves, one above another, of iron grating, which are covered with lime to the depth of about 3 inches. Movable trays are conveniently substituted for the shelves. The lime is sprinkled with water to slake it. The gas, let in below through a large pipe, passes up through the lime, which combines with and retains its impurities, and the gas is then conveyed away by another pipe. The French arrange the slaked lime upon trays in layers with moss, which serves to divide the gas into minute jets and multiply the points of contact with the lime. They spread among the moss a little less than a bushel of lime to the square yard of surface; and they use about $2\frac{1}{2}$ bushels to a ton of coal, the average product of which is less than 7,000 cubic feet of gas to the ton. The purifier is of circular form, and the rim of the cover shuts down into a ring containing water, thus making a gas-tight joint, while the cover can be moved on and off with perfect freedom. The dry lime purifier is generally preferred to the wet lime; the passage of the gas is less obstructed, and the product is less offensive to the neighborhood. By connecting the interior of the purifier by means of a large pipe with the flue of the chimney, the current of air allowed to enter draws up the offensive gases from the lime, and they are decomposed in the hot air of the chimney. This would seem to be a hazardous process, endangering explosion. Tomlinson refers to it, but we have only known the foul gases to be conducted to flues unconnected with fires, or pumped out and passed through copperas to decompose them. The cover of the purifier being raised, the lime can be taken out without causing any annoyance; and it is then sometimes burned in ovens and afterward used a second time, but the common practice is to throw it away after once using.—From the purifier the gas is conducted to the station meter, the instrument for measuring and registering the quantity produced

during any period of time. It is constructed upon the principle of the meters used by each consumer, but on a much larger scale. A cylindrical box more than half filled with water contains a drum supported upon an axis which passes from one end to the other of the outer case. This drum is divided into 4 hollow compartments, each of which has an opening into the central space around the axis, and also slits in the rim communicating with the space next the outer case. The gas is conducted into the central space and flows into one of the partially submerged compartments. As this fills, the pressure of the gas causes the drum to begin to revolve, and as it passes round the next compartment comes in position to be filled, and so on, each chamber as it is submerged in its revolution discharging its measure of gas into the space above the water next to the outer case, from which it is conveyed away to the gas holder. The capacity of the chambers being known, and the number of revolutions recorded by a train of wheel work connected with dials on the outside of the case, the whole quantity of gas passed through is at any time seen. But to give uniform results the water must always be at the same level; as it rises it diminishes the gas capacity of the compartments, and as it sinks it enlarges this, and more gas is passed with each revolution. The station meters are also provided with a clock, to the minute hand of which is attached an index carrying a pencil. By the lines this traces upon a disk of paper attached to a plate which is affixed to and revolves with the axis of the drum, any irregularity in the supply, and the time of its occurrence, are registered. The dials are provided each with a single pointer; one marks the number of tens of cubic feet, another the number of hundreds, another thousands, &c., up to tens of millions. The largest instruments of the kind pass about 650 cubic feet in one revolution of the drum, and register in an hour about 70,000 cubic feet.—The next apparatus is the gas holder or reservoir. It is a cylinder of plate iron suspended or floating with its open lower end in a cistern of water. As the gas is admitted beneath, the cylinder is lifted up by it; and as it is required for consumption, the pressure of the gas holder forces it through the pipes laid for its conveyance. These receptacles are of immense size for the supply of large cities. One in Philadelphia is of the capacity of more than 1,000,000 cubic feet, being 140 feet in diameter and 70 feet high. The imperial gas company of London have one 200 feet in diameter and 100 feet high. To obtain room for gas holders of great height to descend, so that their tops may come down to the level of the water, and the gas be all expelled from them, they are made in sections which shut one within another like the parts of a telescope. The lower edge of each section except the lowest curves up in a flange directed outward, and forming a ring. As the section rises out of the water this ring comes up filled with it, and

catches the flange of the next section below, which is bent inward for this purpose. The water has the effect of making the joint proof against the escape of gas.—Between the gas holder and the main pipe is placed an apparatus called the governor, contrived to regulate the pressure of the gas as it is admitted into the main; and it is found useful to repeat these machines wherever the gas is distributed at points varying considerably in elevation, as from its low specific gravity the pressure increases with the elevation, the rate being $\frac{1}{100}$ of an inch for every foot of difference of height. It has even been recommended to use one for every 80 feet of rise in the ground through which the pipes are carried. In construction it resembles a gas holder, an inverted cylinder being suspended with its lower part in water so that as the gas comes in from below the upper portion is lifted. This carries suspended from its centre a cone of cast iron, turned true, and adapted when raised sufficiently high to fit closely the bevelled opening by which the gas enters the central part of the apparatus. The outlet pipe commences in the upper portion and passes down through the bottom. The cone and cover are nearly counterbalanced by a weight, which passes over a pulley outside of the machine. When the pressure of gas is moderate the cover and cone descend, leaving a wide opening for the gas to enter. When the pressure increases the cone rises and checks the flow.—The gas, being now delivered into the main, is distributed to the various points where it is consumed. Each customer is furnished with his own meter, which registers on the principle explained the quantity he consumes. Small pipes convey the gas from the meter to the various burners affixed at their terminating points. Upon the form and condition of these the economical consumption of the gas in proportion to the light produced in great measure depends. Each one is furnished with a stop-cock upon its own supply pipe, and by means of this the quantity admitted to the burner is regulated. The opening at the end for the gas to escape is often in the form of a narrow slit. This gives to the flame the form of a thin sheet known as the bat's wing; and a similar effect is produced by two small round holes in the end of the burner inclined toward each other. The principle of the Argand burner is explained in the article ARGAND LAMP. In applying this principle to gas, the burner is a hollow ring perforated with holes about $\frac{1}{4}$ of an inch apart, and measuring $\frac{1}{2}$ of an inch in diameter, bored with the greatest accuracy. These are large consumers, but give a brilliant light; and in most burners this is attained at the expense of an unnecessary quantity of gas. Economy in this respect and a flame free from flickering have been most important desiderata in the construction of all new burners, of which there is the greatest variety. No burner in use appears to combine these advantages so admirably as that known as "Gleeson's American gas burner,"

comparative experiments with which, made by Prof. Silliman, jr., gave the most favorable results, a 2 foot burner giving under $1\frac{1}{4}$ inches pressure light equivalent to that of 16 candles. The writer has found it preferable to many other burners tried with especial reference to long continued use as a study light. Very economical and cheaply constructed burners are those of Mr. E. L. Hicks of New York, the peculiarity of which consists in a metallic cap or thimble provided with a circular aperture in the top. This is fitted to slip over an ordinary burner, and when in its place the light from the same flow of gas is perceptibly increased. As measured by the photometer, this increase has been found, according to the experiments of Prof. John Torrey, to amount to 74 per cent. as a minimum, with a 3 feet fish tail burner, to a maximum of 206 per cent. with a 2 feet burner; thus more than trebling the light. The effect seems to be analogous to that produced by placing a thin platinum slip in the flame of a lamp, and is probably owing to a check produced in the consumption which causes the particles of carbon to become incandescent before they enter into combination with oxygen. As the pipes are liable to become foul by oxidation, especially between the burner and the stop-cock, where air mixes with and aids to decompose the changeable compounds contained in the gas, attention should be directed to keeping them clean, and instruments are sometimes furnished by the gas companies for this purpose. Burners of soapstone have recently been introduced in Nuremberg, Germany. They have the advantage of not being affected by the chemical action of gases, nor by high degrees of heat, such as burners are sometimes subjected to in laboratories. The stone is cut into slabs which are exposed in hermetically sealed cases to heat very gradually raised to redness. In two hours they are slowly cooled, then turned to proper shape in a lathe, and boiled in oil, till they become deep brown. On drying they are polished with a woollen rag. The boring requires much care and skill.—A common trouble with gas pipes in severe cold weather is their "freezing up," thus interrupting the flow of the gas. This is owing to the vapors which accompany the gas condensing, and, unless the pipe descends toward the meter, flowing back and obstructing the pipe. This often occurs when the pipe is laid so deep as to seem out of the reach of frost. A simple remedy is to give the pipe a slope toward the meter.—In the use of gas several circumstances are to be considered which affect the estimation in which it is held. Though unquestionably more economical than any other means of producing the same quantity of artificial light, it is commonly used so freely that often no saving is experienced over modes of illumination previously in use. No one is satisfied with an amount of light from gas which was sufficient when furnished by the troublesome oil or candles. From this freedom in consuming it gas tends also to give out much heat and to vitiate the air. Yet, according to the statements

of Dr. Frankland, gases producing light equal to 20 sperm candles generate carbonic acid in the ratio, as compared with these candles, of 5 to 8.8, and heat in nearly the same proportion, and with the best hydrocarbon gases the ratio was, of carbonic acid 2.5 to 8.8, and of heat 19 to 82. Wax was rated with sperm, while tall-oil candles equal to 20 sperm generated 10.1 of carbonic acid and 100 of heat. The effects of the heat and of the vicious air may be remedied in great part by the adoption of a system of ventilation, placing over each burner a hood and pipe for conveying to the nearest flue above the products of combustion. In low rooms this may be desirable, and especially in the use of gas that has not been thoroughly deprived of sulphurous acid.—PORTABLE GAS. Methods have recently been introduced of taking supplies of gas in steamboats and on railroad cars, and renewing these as they are consumed. By one plan sheet iron cases of the capacity of 50 or 60 feet are fitted under the cars and filled as occasion requires from the street mains under ordinary pressure. The tops of the cases are lined with a loose sheet of India rubber, which swells upward as the gas flows in beneath. To expel the gas for use, air is forced in above the lining by the action of a meter running by clock work under uniform pressure. The clock work is impelled by a spring which is wound up by hand, and the action is suspended whenever the valves for the burners are closed. The motion of the cars does not affect the regularity of the supply to the burners. From the permeability of all flexible sheets, this process cannot be regarded as entirely safe from danger of explosion. By the method of the New York car and steamboat gas company the gas is first compressed by a force pump into strong cylindrical gas holders made of boiler plate iron, and measuring 7 or 8 feet in length by about 14 inches in diameter. By the pressure of 20 atmospheres 100 feet of gas is thus put into a space of 5 cubic feet. To secure a uniform rate of discharge when the cylinders are connected with the gas pipes of the car or steamboat in which they are carried, a regulator of improved form is attached to the pipes, by which the aperture through which the gas passes is gradually made to enlarge with the diminution of pressure. In Jersey City a stack of cylinders connected by small pipes serve as a reservoir, into which the gas is pumped at a pressure of about 450 lbs. From this a pipe extends to the railroad station, a quarter of a mile distant, and as the cylinders attached beneath the cars require a new supply, they are simply connected with this pipe and directly filled. The same plan is also applied of late to furnishing houses with gas that are situated at a distance from the public gas pipes.—GAS AS FUEL. Within a few years gas has been applied in stoves constructed for the purpose to furnish heat by its combustion; and being so perfectly under control and directed so readily to produce the required effect, it has in many circumstances proved an economical fuel.

In summer it may be made to heat in suitably arranged apparatus culinary and other vessels without materially adding to the warmth of the apartment; while in winter, consumed in stoves adapted for diffusing heat, it has been made to take the place of other fires, and the application is especially convenient where a fire is only occasionally required a little while at a time. Thus employed, particular attention should be directed to ventilation, the importance of which is liable to be overlooked, as the deleterious gases largely produced do not make their presence directly sensible. In chemical laboratories gas has long been applied to this use. It has been found particularly convenient for heating small crucibles, and by directing through the Argand burner in which it was consumed an annular concentric current of air, intense heat has thus been attainable at any moment, and without loss by its dispersion to other objects. It then came to be applied in many of the mechanical arts, and upright cylindrical stoves of sheet iron were contrived in which the gas, being ignited, heated by its combustion the tools placed for the purpose in the upper part of the stove. The flame is sometimes that of a number of small jets, applied directly to the object to be heated, and in other arrangements the gas is discharged beneath a diaphragm of wire gauze which is placed across the upper part of an upright cylinder of sheet iron. Air also is let in below and mixes with the gas before passing through the wire gauze. Being ignited above, the flame cannot pass down through the gauze into the cylinder. The mixture of a suitable proportion of air serves to add to the intensity and heat of the combustion, but lessens the illuminating power of the gas, which now burns with a blue instead of a yellow flame. This is probably owing to the carbon and hydrogen both simultaneously combining with oxygen furnished by the air disseminated through the gas, while in the ordinary manner of effecting the combustion the hydrogen first burns, and the particles of carbon are made incandescent and luminous before they find their equivalent of oxygen. Small cylinders have sometimes the gas introduced together with a portion of air, the one by a jet and the other by openings made at the base of the cylinder, and the combustion is effected and kept up at the top without the intervention of the wire gauze.

—GAS IN THE UNITED STATES. The first attempts to introduce the use of gas in the United States were at Baltimore, by some accounts in 1816, and by others in 1821. They appear to have been unsuccessful. In 1822 it was introduced into Boston; and in 1823 the New York gas light company was incorporated with a capital of \$1,000,000, but did not enter into successful operation till the year 1827. In 1830 the Manhattan gas light company was incorporated with a capital of \$500,000, which has since been increased to \$4,000,000. The former supplies that portion of the city below Grand street, having 188 miles of pipe laid, of diam-

eters ranging from 4 to 18 inches. It has 3 retort houses, containing 504 retorts and over 160 furnaces; and 6 telescopic gas holders, beside 6 distributing gas holders at different points of its district. The company employs about 400 men, and manufactures 480,000,000 cubic feet of gas per annum. Until the year 1849 rosin and oil were used for producing gas; but the materials generally employed are 2 parts of cannel coal and one of Newcastle. The Albert coal of Nova Scotia, referred to in the article COAL, has lately come into use. It is estimated that a chaldron of the best cannel coal, weighing 27 cwt., makes 12,000 cubic feet of gas; and the Newcastle coal 8,650 feet, beside 14 cwt. of coke, 12 gallons of tar, and 12½ of ammoniacal liquor.—The Manhattan gas light company supplies the streets between Grand and 79th streets. It has 207 miles of pipes laid, of diameters varying from 8 to 20 inches. In 1858 it made 725,821,000 cubic feet of gas, and supplied 25,000 private consumers and 8,600 street lamps. The works, situated on 14th street, East river, and 18th street, North river, embrace 5 retort houses, containing 1,900 retorts and 14 telescopic gas holders, of the aggregate capacity of 4,089,000 cubic feet. The quality of the gas is determined by daily photometric observations at the corner of Irving place and 15th street. The annual consumption of gas coal is 76,000 tons, and 200,000 bushels of hydrate of lime are used for purifying the gas. The number of clerks and men employed is 1,500.—The operations of the Philadelphia gas works belonging to the city are given for 7 years succeeding 1840 by Prof. W. R. Johnson in the American edition of Knapp's "Chemical Technology." The results for 1846 and 1847 are as follows:

Statistics.	1846.	1847.
Cubic feet of gas manufactured...	75,454,000	91,457,000
Bushels of coal of 75 lbs. each carbonized during the year.....	284,108	285,117
Barrels of rosin of 250 lbs. each used with the coal during the year...	4,692	6,545
Sum of the weights of coal and rosin used in the retorts during the year	18,738,225	22,020,025
Proportion of rosin to the whole material distilled, per cent.....	6.25	7.10
Cubic feet of gas produced per ton (2,240 lbs.) of the materials distilled.....	9,090	8,899
Cubic feet of gas from 1 lb. of mixed coal and rosin distilled.....	4.02	3.97
Total number of bushels of coke produced during the year.....	810,042	411,535
Bushels of coke produced from 1 bushel of coal.....	1.22	1.44
Bushels of coke used in heating retorts during the year.....	201,881	206,176
Bushels of coke used in heating retorts per ton of the mixed coal and rosin.....	24.1	28.0
Percentage of all the coke produced, used in heating retorts.....	65.0	5.73
Struck bushels of lime used for purifying gas during the year...	61,818	80,508
Cubic feet of gas purified by 1 struck bushel of lime.....	1,290	1,186
Cost of coal per bushel, in cents...	21	17½
Cost in cents of rosin per barrel of 250 lbs.....	75	80
Cost of lime per bushel in cents (in 1845, 2.44).
Cost of gas made during the year,		

Statistics.	1866.	1867.
exclusive of interest on capital, but including all payments for materials, freights, rents, salaries, wages, repairs, and all incidental expenses of the manufacture and distribution.....	\$121,054.60	\$96,527.43
Cash receipts during the year for gas, coke, lime, tar, &c.....	180,888.08	209,684.76
Price paid for gas per 1,000 cubic feet.....	\$2.60-\$2.50	\$2.50

The use of gas has continued to spread among the chief cities and towns of the United States with great rapidity, especially in the last few years, till the gas interest, it is estimated, now represents a capital of \$34,920,000 in the United States, divided among 237 companies; and in Canada, \$1,040,000, among 6 companies. In New York alone there are 43 cities and towns lighted with gas, and the number of these is constantly increasing. The lowest price anywhere paid for gas is at Pittsburgh, Pa., \$1.50 per 1,000 cubic feet. The highest price, \$7.00, is paid at Auburn and Watertown, N. Y., Belfast, Me., Charlotte, N. C., and some other places. A monthly paper devoted to the interest, was commenced in New York in July, 1859, entitled the "American Gas Light Journal."—The following table presents the general statistics of the production and cost of gas in the principal cities of the United States:

Name of gas light company.	Cubic feet of gas sold per annum.	Price to private consumers per 1,000 cub. ft.	Average cost of coal per ton of 2,000 lbs.
Manhattan, N. Y.	725,321,000	\$2.50	\$6.50 to 11.00*
New York, N. Y.	430,000,000	2.50	
Philadelphia, Penn.	432,000,000	2.18 net	6.50
Boston, Mass.	200,000,000	2.50	5.00 to 12.00*
Brooklyn, N. Y.	168,000,000	2.85 net	7.25 to 8.15
Cincinnati, Ohio.	96,703,900	2.50	3.40
Chicago, Ill.	86,250,810	8.50	5.78
St. Louis, Mo.	74,500,000	8.50	7.50
N. Liberties, Phila.	70,000,000	2.88 net	6.25
Pittsburg, Penn.	54,720,000	1.50 net	1.25
Providence, R. I.	41,437,583	8.00 net	7.90*
Albany, N. Y.	40,250,000	3.00	6.75 to 8.00
Louisville, Ky.	33,750,000	3.00	
Williamsburg, N. Y.	33,493,083	3.50	6.25 to 9.50
Troy, N. Y.	28,000,000	3.60 net	7.90*
Richmond, Va.	27,000,000	2.35	4.15
Rocheater, N. Y.	25,000,000	3.00 net	5.38
Lowell, Mass.	21,000,000	3.75	6.50
Cleveland, Ohio.	20,000,000	3.00	4.25
Detroit, Mich.	20,000,000	3.50	5.00
Jersey City, N. J.	19,234,000	3.00	7.89*
Milwaukee, Wis.	19,042,560	3.50 net	6.00

Worcester, Mass.	9,000,000	3.50	6.16
Lawrence, Mass.	9,000,000	2.50	5.05
Belen, Mass.	8,718,890	3.50 net	

More complete information about U. S. gas companies may be found in a pamphlet recently published by the Louisville gas company, entitled "The Reply of the Louisville Gas Company to the Report of the Committee on Gas and Water, addressed to the Mayor and General Council of the City of Louisville." It contains a

mass of information collected from 91 responses to a circular containing 13 interrogatories addressed to 188 gas companies.

GASCOIGNE, GEORGE, an English poet, born about 1587, died in Stamford, Oct. 7, 1577. He was a spendthrift, was disinherited by his father, served the prince of Orange as a soldier of fortune, and returned to England with a reputation for bravery. A complete edition of his works was published in 1587. His poem the "Steele Glas" is the earliest English satire, and has been highly praised by modern critics. His comedy of "The Supposes" is the oldest extant prose play in the language, and has been supposed to have been used by Shakespeare in the "Taming of the Shrew."

GASCOIGNE, SIR WILLIAM, lord chief justice of England under Henry IV. and Henry V., born in Gawthorpe, Yorkshire, about 1350, died about 1420. During the reign of Richard II. he acquired the reputation of a learned and skilful lawyer, and numbered among his clients Henry of Bolingbroke, who, upon his accession to the throne, appointed him chief justice of the king's bench, a position which he filled with singular ability and intrepidity. An illustration of his courage is afforded in his refusal to sanction the execution of Scrope, the rebellious archbishop of York, on the ground that the lay courts had no jurisdiction over a prelate. That act of his life, however, for which he is best known, was the committal of the prince of Wales for an assault upon him, while sitting on the bench, upon hearing which Henry IV. is reported to have said: "Happy the king that has a judge so firm in his duty and a son so obedient to the law." This anecdote, though considered of doubtful authenticity, suggested to Shakespeare the well known scene (2d part of Henry IV., Act v., sc. 2) in which the young king, Henry V., commends the conduct of Gascoigne on this occasion, and continues him in his office. The retaining of Gascoigne in office, however, was long considered a breach of historical truth, as he was supposed to have died before Henry IV. Recent investigations having satisfactorily shown that he was summoned to the 1st parliament of Henry V., and that he was alive on Dec. 15, 1419, which is the date of his will, Lord Campbell ("Lives of the Chief Justices") concludes that he survived Henry IV. and was reappointed chief justice of the king's bench.

GASCONADE, an E. co. of Mo., bounded N. by the Missouri river, and intersected by the Gasconade river; area, 540 sq. m.; pop. in 1856, 6,900, of whom 46 were slaves. The surface is much broken, and the soil of the hilly portions is poor, but the low lands and river bottoms are mostly fertile. Iron ore is found in abundance, sulphur and saltpetre are obtained, and copper has been discovered on Bourbeuse creek. Within a few years considerable attention has been given to the manufacture of wine. The agricultural products in 1850 were 20,427 bushels of wheat, 190,913 of Indian

* Per ton of 2,240 lbs.

corn, 26,269 of oats, and 5,081 lbs. of wool. There were 4 tanneries, 1 grist mill, 2 newspaper offices, 3 churches, and 73 pupils attending public schools. The county is well supplied with water power and timber, and has quarries of limestone and buhrstone. Capital, Hermann.

GASCONY (Fr. *Gascogne*), an old province in the S. E. corner of France, bounded N. by Guienne, E. by the county of Foix and Languedoc, from which it was partly separated by the upper Garonne, S. by the Pyrénées and Béarn, and W. by the Atlantic (the gulf of Gascony). It was originally inhabited by a population of Iberian blood, received from the Romans the name of *Novempopulonia* or *Aquitania Tertia*, and changed it to that of Gascony about the middle of the 6th century, when it was occupied by the Vascones, a tribe of northern Spain, whom the Goths had driven across the Pyrénées. It was more than once invaded by the Merovingian kings, but was never entirely subjugated until the time of Charlemagne. The supremacy of the French crown being finally established, the country was placed under the direct sovereignty of the duke of Aquitaine. Through the marriage of Eleanor with Henry Plantagenet, Gascony, in conjunction with the whole country which that princess held south of the Loire, fell to the crown of England in 1152. For 300 years it remained under the same allegiance, and returned by conquest to France in 1453. It formed afterward, with Guienne, one of the great governments of that country, and is now divided into the 3 departments of Hautes-Pyrénées, Gers, and Landes.

GASCOYNE, WILLIAM, the inventor of the micrometer, born in England about 1621, killed fighting for Charles I. at Marston Moor, July 2, 1644. The instrument, as constructed by him, consisted principally of 2 parallel wires or metallic plates, capable of being moved, which were placed in the focus of the eye-glass of the telescope. The image was comprehended between these, and by means of a scale for the measure of angles its diameter was determined. Gascoyne used his instrument in various astronomical observations, and in determining the magnitude or distance of terrestrial objects.

GASKELL, ELIZABETH C., an English authoress, born about 1820, is the wife of a Unitarian clergyman residing in Manchester. Her maiden name was Stevenson. Her first novel, "Mary Barton," published in 1848, is a striking picture of the daily life of a large manufacturing town, the materials for which were furnished by her close observation of the social character and condition of the working classes in Manchester. The pathetic power of many of the scenes delineated, the broadly drawn characters, and the literary merit of the book gave it not a little popularity, and Mrs. Gaskell at once took a position among the first writers of fiction of the day. She next became a contributor to "Household Words," one of her longer tales for which, "North and South," was reprinted in 1855, having been preceded

by the "Moorland Cottage" (1850), a Christmas story, and by "Ruth" (1853), a tale of considerable power, and, like all her works, founded on her observation of the habits and privations of the poor. Her more recent fictions are the series of papers entitled "Cranford" and "Lizzie Leigh," republished from her contributions to "Household Words." Shortly after the death of her friend Charlotte Brontë, she contributed a memoir of her to the London "Daily News," and in 1857 appeared her "Life of Charlotte Brontë" (2 vols. 8vo.). Her last work is entitled "Round the Sofa" (2 vols. 8vo., 1859).

GASPARIN, AGÉNOR ÉTIENNE, count, a French publicist, born in Orange, July 4, 1810. He was private secretary to M. Guizot, minister of public instruction, and was afterward employed at the ministry of the interior, and in the department of trade and agriculture. From 1842 to 1848 he was a member of the chamber of deputies. A zealous Protestant, he vindicated the rights of his brethren, and claimed unlimited freedom for evangelical preaching and colportage. He also insisted upon the immediate emancipation of slaves and the suppression of prostitution. On the revolution of February he retired to Switzerland. He has published essays on various questions of philosophy or political economy, such as *Esclavage et traite* (1838); *De l'affranchissement des esclaves* (1839); *Intérêts généraux du Protestantisme Français* (1843). His work *Des tables tournantes, du surnaturel en général, et des esprits* (3 vols.) has been translated and published in the United States.

GASPE, an extreme E. co. of Canada East, bordering on the river and gulf of St. Lawrence; area, 4,063 sq. m.; pop. in 1851, 10,904. It constitutes with Bonaventure co. the district of Gaspé. It has a mountainous surface, diversified by many fertile valleys, and traversed by St. Anne, Dartmouth, and other rivers. The inhabitants are engaged chiefly in the lumber trade, and the whale, cod, salmon, mackerel, and herring fisheries. The settlements are confined almost wholly to the coasts, which are lined with excellent harbors.—GASPE, or GASPE BASIN, a village and port of entry of the above county, occupying a wide area in the united townships of York and Gaspé Bay South, on the S. side of a harbor formed by Gaspé bay, 496 m. N. E. of Quebec; pop. about 550. It is the seat of an important cod fishery, and has several whaling vessels. In 1851 it contained 1 saw mill, 8 grist mills, and 8 churches. The value of imports amounted to \$53,352, and the exports to \$141,740.

GASSENDI, or GASSEND, PIERRE, a French philosopher, called by Gibbon the most learned of the philosophers and the most philosophic of the learned men of his age, born in Champtercier, a village near Digne, in Provence, Jan. 22, 1592, died in Paris, Oct. 24, 1655. Of an obscure rustic family, his childhood was distinguished by purity and gentleness of character and by astonishing precocity. It is stated that

at the age of 4 he played the part of a preacher and delivered sermons before his youthful companions, and was wont to creep out by night to watch the stars; that at 7 he made ingenious explanations to his playmates of the apparent motion of the moon through the clouds; that at 10 he strikingly harangued the bishop of Digne in Latin, on occasion of a pastoral visitation; and that at 18, already known as the little doctor, he adopted the motto *Sapere aude* ("Dare to be wise"), and composed slight comedies in mingled prose and verse, which were played by him and his associates in noble houses. While receiving lessons from the curate of the village he had been accustomed to pursue also solitary studies by the light of the church lamp. He completed his philosophical course at Aix under Father Fesaye, who declared that he often forgot whether the young Gassendi was his pupil or master; and at the age of 16 was appointed professor of rhetoric at Digne. Being destined for the church, he returned within a year to Aix to study theology, received the degree of doctor at Avignon, obtained a small benefice at Digne, and in 1616 was simultaneously elected to the two chairs of philosophy and theology at Aix, of which he chose the latter. He shared in the rising discontent with the reigning scholastic philosophy, collected many critical notes on Aristotle, and employed his leisure in the study of anatomy with Peiresc, president of the university of Aix, and in astronomical observations with Joseph Gautier, prior of La Valette. Even astrology, which he afterward strenuously combated as a delusion, was now one of the objects of his researches. In 1622 he resigned the professorship in order to devote himself more entirely to study. In 1624 he published at Grenoble his *Ezercitationes Paradoxicæ adversus Aristotelæos*, in which, while professing his faith in the church, he distinguished two things which till then had often been deemed inseparable, the church and the scholastic philosophy. The work attracted much attention. Gassendi had designed to complete it in 5 books, but did not continue it beyond the first two, being reminded perhaps of the fate of Ramus and Giordano Bruno by the opposition which he met, and by a decree of parliament forbidding any opinion to be held or taught contrary to the ancient and approved authors. In the same year he was appointed provost of the cathedral of Digne, but the appointment was contested, and not finally confirmed till 10 years later. For the purpose of forming friendships with the literati of the age, he travelled through Provence and Dauphiny, resided a year in Paris, and began a correspondence with Galileo, in a letter to whom he expressed his concurrence with the Copernican system. On returning to Digne he continued his ecclesiastical duties and various studies, preaching frequently and with great success. In 1628 he visited Paris, travelled with Lullier in the Netherlands, and wrote, at the instance of Mersenne, a lively treatise (1630)

against the mystical and alchemistic doctrines of Robert Fludd. He was a constant correspondent of Kepler, who before his death had publicly announced that Mercury and Venus would pass over the disk of the sun on Nov. 7, 1631. Gassendi was the first to observe the passage of Mercury, and wrote a minute account of the phenomenon. On the appearance of the *Discours de la méthode* and the *Méditations* of Descartes, a controversy arose between the two philosophers, representatives of opposite schools, the antagonists respectively addressing each other as *O Anima* (spirit) and *O Caro* (flesh). The daring and original genius of Descartes, drawing his materials from his own mind, was contrasted with the erudition and critical acumen of his opponent, who excelled him in caution and courtesy. In 1645 Gassendi received from Cardinal Richelieu the appointment of mathematical professor in the royal college of France, where a numerous and distinguished audience attended his lectures; and two years later he published at Lyons his biographical treatise, *De Vita, Moribus, et Placitis Epicuri*, which was followed by his *Syntagma Philosophiæ Epicuriæ* (Lyons, 1649). For many years he had applied himself to the preparation of these works, searching libraries and comparing texts and annotations, and they form together a complete review of the life, eulogy of the character, and reconstruction of the philosophical system of Epicurus. The Epicurean ethics and physical theory of atoms and a vacuum are elaborately vindicated and conformed to the principles of Christianity and the discoveries of modern science, those dogmas of the system being refuted which contravene the interests of religion. His feeble health obliging him to resign his professorship, he retired to the south of France, lived two years in Toulon employed in constructing his philosophical system after meditating on all the philosophers, and in 1653 returned to Paris to consult libraries, and to give the final touches to the work that was to be the most complete and learned statement of his opinions. He was soon obliged to cease from labor, and after a lingering illness his death was hastened by the excessive phlebotomy then in practice by physicians. His *Syntagma Philosophicum*, an encyclopædic view of the entire circle of science, was published posthumously, forming the first two volumes in a complete edition of his works, edited by Montmor and Sorbière (6 vols., Lyons, 1658). It is divided into 3 parts, logic, physics, and ethics, is elaborated with great prodigality of learning and minuteness of criticism, and contains an eclectic philosophy formed by the union of ideas borrowed from various schools rather than a new system. Though formerly regarded as the precursor of the sensational philosophers of the last century, his doctrine of the intellect in the *Syntagma* proves that he was far removed from them. For though he adopts the maxim that "there is nothing in the intellect which has not been in the senses," and maintains that the

phantasia or imaginative faculty is but the counterpart of sense, reproducing material images, he yet affirms that the intellect, which is immaterial, immortal, and the characteristic distinction of man, has reflex operations, and apprehends universal and abstract ideas to which neither the senses nor the imagination can attain. His system is therefore akin to that of Locke rather than of the French followers of Locke, and even a part of his phraseology, as the *actiones reflexivæ*, anticipates that of the "Essay on the Human Understanding." It does not appear, however, that Locke was acquainted with his writings. There is an apparent discrepancy between the language of Gassendi in his latest work and that employed in his controversy with Descartes, when it was his object to urge all possible objections rather than to state his own opinions. Not only as a metaphysician, but as an astronomer, geometer, anatomist, Hellenist, historian, and elegant writer, Gassendi merits distinction. He was the personal friend of most of the learned men of his time, the first disciple in France of Bacon, and the precursor of Newton. The aurora borealis, the parhelia, the conjunctions of Venus and Mercury, the occultations of the satellites of Jupiter, and the properties of the magnetic needle were among the subjects of his researches. He wrote the lives of the principal astronomers of his age, and in the preface gave a brief and admirable history of astronomy. He was esteemed personally for amiability, modesty, and moderation, and was long remembered by the peasants around Digne, not as a savant, but as a pious and exemplary priest. The latest complete edition of his works is that edited by Averrari (6 vols., Florence, 1728). An abridgment by Bernier (Paris, 1678) has been several times republished. His life has been written by Sorbière (for the first edition of his collected writings, Lyons, 1658), and by Bougerel (Paris, 1687).

GASTEROPODA (Gr. γαστήρ, belly, and πούς, ποδος, foot), a class of the mollusca distinguished by the under side of the body forming a single muscular foot, on which the animal creeps or glides. The snails, limpets, chitons, &c., are examples of this class. They are divided into two natural groups, one breathing air (*pulmonifera*), the other water (*branchifera*). These form the 4 orders of *probranchiata*, *pulmonifera*, *opisthobranchiata*, and *nucleobranchiata*. The shell is usually spiral and univalve, but sometimes tubular or conical; in the chiton it is multivalve. Some marine species, as the *doris*, *phillidia*, &c., have no shells. Some species are provided with a horny or shelly operculum, which forms the bottom of the foot, and when withdrawn closely shuts the aperture of the shell, to which it is firmly held by the strong muscles of this part of the body. In other species, as the limpet, patella, &c., the animal uses the expanded surface of the foot for attaching the shell firmly to rocks and other surfaces; the air being suddenly expelled from

beneath this surface, the shell is held closely to the rock, as if by strong muscular power.

GASTON, a S. W. co. of N. Carolina, bordering on S. Carolina, bounded E. by Catawba river, and intersected by Catawba creek; area, about 350 sq. m; pop. in 1850, 8,073, of whom 2,112 were slaves. It has a diversified surface and an excellent soil. The productions in 1850 were 329,377 bushels of Indian corn, 51,762 of wheat, 535 bales of cotton, and 5,625 tons of hay. The value of the gold obtained during the same year from mines in this county was \$97,786. There were 7 saw mills, 1 iron forge, 19 churches, and 1,520 pupils attending public schools. Value of real estate in 1857, \$835,281. Taken from Lincoln co. in 1846, and named in honor of Judge William Gaston. Capital, Dallas.

GASTON, WILLIAM, an American jurist and statesman, born in Newbern, N. C., Sept. 19, 1778, died in Raleigh, Jan. 28, 1844. He was the son of Alexander Gaston, an eminent physician of Newbern, who was a prominent patriot in the early days of the revolution, and was murdered by a band of tories in the presence of his wife and children. Mr. Gaston was graduated at Princeton, N. J., in 1796, with the highest honors. Returning to Newbern, he studied law, and was admitted to the bar in 1798. Two years later he was elected to the senate of North Carolina, and subsequently to the house of commons, of which he was chosen speaker in 1808. While in the legislature he drew up the statute regulating the descent of inheritances, and the passage of the act establishing the supreme court system of the state was mainly due to his advocacy. In 1808 he was chosen by the federalists a presidential elector, and in 1818 he was elected to the U. S. house of representatives, where he served for 4 years, and, by his prudence, eloquence, and skill in debate, acquired a national reputation. He was one of the most influential leaders of the federal party. He opposed in a forcible speech the loan bill, which proposed during the war with Great Britain to place \$25,000,000 at the disposal of the president, as was generally understood, for the conquest of Canada. His speech, which was widely read, and greatly admired, embraced a thorough discussion of the policy, object, and management of the war. He also made an able speech against the adoption of the previous question as a method of stopping debate in the house. In 1817 he retired from congress to devote himself to his profession. He soon attained the foremost rank in the bar of North Carolina, and for a long period was engaged in all important cases in the state. The chief of these was the "Granville case." This was a suit instituted by the English Earl Granville, the heir of one of the lords proprietors of North Carolina, to try the question of his title to a tract of land covering two-thirds of the state, which he claimed under the original charter granted by Charles II. If Earl Granville had gained the suit, a large proportion of the freeholders of North Carolina would have been

deprived of their estates. The prosecution of a claim of this sort was necessarily very unpopular: but disregarding the clamor of the multitude, and the odium he incurred, Mr. Gaston accepted the post of counsel for the claimant. "He would not," he said, "that a foreigner should fail of justice in our country for want of an advocate." In 1835 he was a member of the convention to revise the constitution of North Carolina, and was placed on all the principal committees, took a leading part in all important debates, and in a great measure guided the business of the convention. He spoke and voted against the proposition to deprive free colored men of the right of suffrage, which at that time they possessed, but which was taken from them by the new constitution. In 1834 he was made a judge of the supreme court of North Carolina, for which office his character, tastes, and intellectual qualities eminently fitted him, and which he refused to abandon for a seat in the senate of the United States. He was a Roman Catholic, and by the constitution of North Carolina, as commonly interpreted, was therefore incapable of holding any state office; but such was the universal regard for his character and ability that the clause in the constitution against the Catholics became a dead letter. He continued in this office till his death, which took place very suddenly. He fell lifeless in the midst of an animated conversation, in his last words declaring his faith in the "All-wise and Almighty."

GASTON DE FOIX, duke of Nemours, a French general, born in 1489, killed at Ravenna, April 11, 1512. He was the son of Jean de Foix, viscount of Narbonne, and of Marie d'Orleans, sister of Louis XII. In 1505 he was made duke of Nemours. In the beginning of 1512, at the age of 23, he was appointed commander of the French army in Italy, to carry on the war with Venice, the pope, and King Ferdinand of Spain, who had formed a "holy league" against Louis XII. of France. Notwithstanding his youth, he was ripe in understanding, and possessed consummate military talents. In less than a fortnight after taking command, by making rapid marches through the snow in mid-winter, he raised the siege of Bologna, defeated the Venetian army under the walls of Brescia, and on the same day carried that city by storm. A few weeks later, on April 11, he brought the allied army to a decisive action under the walls of Ravenna, and, in one of the most hotly contested battles ever fought, defeated them with a loss on both sides of 20,000 men. The Italian forces were completely routed, but the famous Spanish infantry, which was then considered the best soldiery of Europe, retreated in good order with unbroken ranks. Gaston de Foix, flushed with victory, was exasperated at the defiant manner in which they left the field, and charged them rashly in person, followed by Bayard and about 20 other knights. He broke their line, but his horse was wounded, and fell in the midst of the enemy. His followers shouted to the Spaniards to spare him, "for he was the brother

of their queen," Ferdinand of Spain, after the death of Isabella, having espoused Gaston's sister, the princess Germaine de Foix. But Ferdinand's second marriage was not popular with the Spaniards, and they gave no heed to this appeal, but despatched Gaston with a multitude of wounds, of which 15 were in the face. When Bayard reached him he was already dead. His loss so disheartened the French that they reaped little advantage from their great victory. Louis XII. exclaimed on hearing the news, that he would give up every foot of territory he had in Italy if he could so recall to life his gallant nephew and the brave men who had fallen with him. A monument in the neighborhood of Ravenna marks the place where he fell. "There are few instances in history," says Prescott, "if indeed there be any, of so brief, and at the same time so brilliant a military career as that of Gaston de Foix; and it well entitled him to the epithet his countrymen gave him of 'the thunderbolt of Italy.' He had not merely given extraordinary promise, but in the course of a very few months had achieved such results as might well make the greatest powers of the peninsula tremble for their possessions. His precocious military talents, the early age at which he assumed the command of armies, as well as many peculiarities of his discipline and tactics, suggest some resemblance to the beginning of Napoleon's career."

GASTRO JUICE. See DIGESTION.

GATAKER, THOMAS, an English ecclesiastic, born in London in 1574, died about 1654. He wrote several works illustrative of the Scriptures. In 1642 he was chosen member of the assembly of divines at Westminster. In 1648 he remonstrated, in conjunction with 47 of his brethren, against the proceedings of the long parliament in relation to the king. In 1652 he published a critical edition of Marcus Aurelius's "Meditations," with notes, and an introductory discourse on the philosophy of the stoics. The best edition of his works is that published at Utrecht in 1698, in 2 vols. folio.

GATES, a N. E. co. of N. Carolina, bordering on Va., bounded S. W. by Chowan and Nottaway rivers, the former of which is here navigable; area, 853 sq. m.; pop. in 1850, 8,426, of whom 8,871 were slaves. The surface is generally level, and much of it is covered with oak and pine timber. The Dismal Swamp occupies the extreme E. part. The principal exports are Indian corn, tar, and lumber, and the productions in 1850 amounted to 28 bales of cotton, 119,678 bushels of sweet potatoes, 810,188 of Indian corn, and 4,204 of wheat. There were 8 corn and flour mills, 8 saw mills, 6 shingle mills, 18 churches, and 520 pupils attending public schools. The county was formed in 1779, and named in honor of Gen. Horatio Gates. Value of real estate in 1857, \$780,824. Capital, Gatesville.

GATES, HORATIO, a major-general in the U. S. army, born in England in 1728, died in New York, April 10, 1806. He early entered the British army, and was an officer under

Braddock, at whose defeat in 1755 he was severely wounded. After the peace of 1763, he purchased an estate in Virginia, where he resided till the organization of the continental army in 1775. Appointed adjutant-general with the rank of brigadier, he accompanied Washington to Cambridge in July, 1775, and in June, 1776, received the chief command of the army which had just retreated from Canada. In the autumn following he joined Washington in the Jerseys, with a considerable detachment, and in March, 1777, in effect superseded Schuyler in the command of the northern army, and was superseded by him in May. When, however, Schuyler was obliged to retreat down the Hudson by the disasters which followed the loss of Ticonderoga, Gates was reinstated in the command by congress, Aug. 4, 1777. The surrender of the British army at Saratoga, which soon followed, gave to him a brilliant military reputation, though it was in large measure due to the skilful previous operations of Schuyler. In the winter of 1777-'8 "Conway's cabal" intrigued to wrest the supreme command from Washington and to bestow it upon Gates. The latter was engaged in no important military operations till in June, 1780, he was appointed to the command of the southern forces. A caution that was given him not to exchange his northern laurels for southern willows proved prophetic, for the disastrous battle of Camden (Aug. 6) blasted his military fame, and he was superseded by Gen. Greene. His conduct was scrutinized by a committee of congress, and he was not acquitted of blame and restored to his military position till after the surrender of Cornwallis. On the conclusion of peace he retired to his estate in Virginia, whence he removed in 1790, after emancipating all his slaves, to the city of New York.

GATESHEAD, a municipal and parliamentary borough of Durham, England, on the right bank of the river Tyne, opposite Newcastle, with which it is connected by a viaduct and stone bridge of 9 arches; pop. in 1851, 25,568. Its manufactures comprise ships, anchors, chain cables, nails, hemp, wire ropes, &c. There are extensive collieries and grindstone quarries in the vicinity.

GATH, one of the 5 chief cities of Philistia, often mentioned in the history of David and his successors. The giant Goliath, who was slain by David, was either a native or an inhabitant of Gath. It was for centuries alternately under the power of the Jewish kings or independent, except a short period when it was under Syrian rule. In the time of Jerome it was a "very large village." Modern travellers give no description of the place.

GAUDEN, JOHN, an English bishop, supposed by some to have been the author of the *Eikon Basilike*, born in Mayland, Essex, in 1605, died Sept. 20, 1664. In the early part of his life he belonged to the popular party. After the outbreak of the civil war, he hesitatingly submitted to the Presbyterian discipline, omitted the lit-

urgy from the church service, and even subscribed to the covenant, although he secretly wrote a treatise against it. After the restoration he was appointed chaplain to Charles II., and successively created bishop of Exeter and of Worcester. He claimed the authorship of the *Eikon Basilike*, or the "Portraiture of his Sacred Majesty in his Solitudes and Sufferings," a work which was once almost universally attributed to Charles himself, and which in one year went through 50 editions. Mr. Hallam and Sir James Mackintosh pronounce his claim valid.

GAUDENTIUS, a Latin theologian, bishop of Brescia, about the end of the 4th century. He was elected bishop by the clergy and people when very young, but declined the office till both the expostulations of St. Ambrose and threats of excommunication if he persisted in refusing prevailed over him. Little is known of his life, the most important event being his embassy to the court of Arcadius in 405 to carry aid to St. Chrysostom, for which the latter in one of his letters paid him an eloquent tribute of gratitude. There remain 21 discourses by him, written in a simple and dry style, though full of allegorical and imaginative conceptions.

GAUDICHAUD-BEAUPRÉ, CHARLES, a French botanist, born in Angoulême, Sept. 4, 1789, died in Paris, Jan. 26, 1854. In 1817 he accompanied, in the capacity of pharmaceutical botanist, the scientific expedition of Freycinet. The vessel on which he was, the *Uranie*, was wrecked upon the Falkland islands in the spring of 1820, and of the 4,175 botanical specimens which he had collected upward of 2,500 were lost. Upon his return to France he prepared the botanical history of the voyage. In 1830-'33 he took part in the expedition which explored the coast of South America in the *Hermine*, and subsequently circumnavigated the globe again in the *Bonite*. The remainder of his life was devoted to the classification of his specimens and the preparation and publication of his notes, and he carried on an acrimonious controversy with Mirbel on the subject of the process of vegetable growth. In the course of his life he was engaged in 29 duels, from most of which his skill as a swordsman enabled him to escape unharmed. He was nevertheless, according to his friends, averse to duelling.

GAUGING, the operation of measuring the capacity of barrels and other vessels of similar form. It is performed either by measuring the various dimensions of the cask, and then calculating by arithmetical rules the contents, according to the geometrical figure which the cask most nearly resembles, or else by simply measuring the diagonal distance from the bung to the opposite side of one head of the cask, and assuming all casks to be of one shape. In the latter method no calculation is needed, as the number of gallons is engraved directly on one side of the same gauging rod by which the dimension in inches is measured. If the cask is not full, it is also necessary to measure

the perpendicular distance from the bung to the surface of the liquor.

GAUL (*GALLIA*), the name applied by the Romans to two great divisions of their empire, distinguished from each other by the designations Cisalpine and Transalpine (in regard to Rome). Of these, Cisalpine Gaul (*Gallia Cisalpina* or *Citerior*), comprising the north of Italy to the confines of Etruria and Umbria, was divided by the Po (*Padus*) into Cispadane and Transpadane. It was also called *Gallia Togata*, or Romanized Gaul, from the inhabitants wearing togas like the Romans, and in contradistinction to the S. E. province of the Transalpine country, which was called *Braccata* from the *bracca* or wide trousers of its people. It was bounded N. W. and N. by the Alps, E. by the Athesis (now Adige), S. E. by the Adriatic, S. by the Rubicon, the Apennines, the Macra (now *Magra*), and the mountains of Liguria. Transalpine Gaul (*Gallia Transalpina* or *Ulterior*) was bounded W. and N. by the sea, E. by the Rhine, S. E. by the Alps, and S. by the Mediterranean and the Pyrénées, thus comprising not only the whole of modern France and Belgium, but also parts of Sardinia, Switzerland, Germany, and Holland. Both divisions were inhabited mostly by people of Celtic race (Gaelic and Kymric), called by the Romans in general Gauls (*Galli*), by the Greeks *Κέλται* or *Γαλαται*; the Celto-Teutonic, Teutonic, Celto-Iberian, Iberian, Tuscan, Greek, and other elements of the population were comparatively small. (See *CELTA*.) These Celts or Gauls, a branch of the great Indo-European family of nations, had left their Asiatic homes at a period preceding the dawn of European history, and had occupied the western regions on the Rhine, Seine, Rhone and Garonne, Ebro and Tagus, as well as the islands of Britain, when the Roman state was still in its infancy. Of a turbulent, roving, and warlike disposition, they had scarcely settled on the shores of the Atlantic, which stopped their migration westward, when some of their tribes commenced entering northern Italy, according to Livy, under Belovesus, a nephew of King Ambigatus, in the time of Tarquin the Elder. Others are said by the same historian to have taken their direction toward the Hercynian forest, under Sigovesus, another nephew of Ambigatus. Still others appear later, it is uncertain whence coming, in Macedon, Thrace, and Greece, where they burned Delphi, 279 B. C., and even in Asia Minor, where they founded Galatia or Gallo-Græcia, in Syria, and in Egypt. Tall, impetuous, and extremely reckless, with long hair and mustaches, they appeared terrible, not only to the effeminate people of the eastern countries, but to the Romans themselves. They fought on horseback, armed with large bucklers, lances, and swords. They were fond of adventure, greedy of gold, and boastful, made the use of arms a profession, served as mercenaries even in Carthage, and challenged foes and friends to single combats. Even where they were settled they preferred hunting and grazing to

agriculture. They were quick of temper, sudden in resolution, and inconstant, and therefore apt to conquer, but not to keep, to destroy, but not to make lasting foundations. There are no precise historical dates for the consecutive invasions of Cisalpine Gaul by the Celts; they are supposed to have occupied several centuries. Tribe followed tribe, and finally we find the Salassians settled in the vicinity of Ivrea (*Eporedia*), the Insubrians about Milan (*Mediolanum*), the Cenomani in the region of Verona and Mantua, the Boii in the country now forming the duchies of Parma and Modena and about Bologna (*Bononia*), the Lingones about Ravenna, the Senones, who came last, in the S. E. of Cispadane Gaul, and other tribes in various other parts of the country. It was not long after the conquest of Veii by the Romans that this people came in contact with the Gauls. These invaders had conquered the northern possessions of the Etruscan confederacy while the Romans were making their attacks on its southern districts. They had pushed the Umbrians southward, taken Melpum (896 B. C.), crossed the Apennines under one of their Brenni, and advanced as far as Clusium. The Tuscans of this city now sought aid from the Romans, who, however, sent no army to their assistance, but despatched the Fabii as envoys to deter the barbarians. The envoys only provoked them, and drew their sword upon Rome. Brennus broke up the camp before Clusium, crossed the Tiber, routed the Romans on the Allia, entered Rome through open gates, and pillaged it; but finally, after an obstinate siege of the capitol, he sold his conquest for gold and retired with his army. Rome long and well remembered the "day of the Allia" (July 18) and all the terrors of the first Gallic invasion. All others proved disastrous to the barbarians. In 367 they were routed near Alba by the old Marcus Camillus, who won there his last victory. In 361 another host, like the first of the Senonian tribe, encamped before the Anio bridge, but marched further toward Campania before fighting a battle. Shortly after returning from Campania they renewed their ravages, and fought unsuccessfully against the dictators Ahala and Peticus. In 350 they again encamped before Rome, keeping it in perpetual terror; but in the following year L. Furius Camillus, a nephew of Marcus, compelled them to retire, an event the fame of which reached even the contemporary Aristotle in Greece. When in a later period the Gauls assisted the Umbrians and Etruscans against the more and more advancing Romans, they were routed in the battle of Sentinum (296), where many of them fought on war chariots, and near the lake Vadimon (283). These disasters, suffered chiefly by the Senonian and Boian Gauls, put an end to the Gallic wars in Italy for nearly 60 years. The Romans, who had conquered Umbria, founded their first colony in Cispadane Gaul, in the land of the Senones, calling it *Sena Gallica* (now Sinigaglia); Ariminum (Rimini) was founded afterward. The Gauls were too

much weakened to offer any opposition. But strengthened by the arrival of large bodies from beyond the Alps, they took up arms again in 225, and crossed the Apennines, but were soon compelled to retreat, and were routed at Telamon. The Romans continued the war with great vigor, conquered the land of the Boii, crossed the Po, on the opposite banks of which they soon after founded Cremona and Placentia (Piacenza), and subdued the Insubrians (221). The details of all these military events, as for instance the single combats of T. Manlius Torquatus (361) and M. Valerius Corvus (349) with gigantic Gauls, belong to the history of Rome, or rather to the legends of its heroes. When Hannibal crossed the Alps (218) he was eagerly joined by numerous Gauls, but after his final defeat (201) Cisalpine Gaul became an easy prey to the victorious legions. It was made a Roman province at the beginning of the following century, received numerous new Roman colonies, became civilized, industrious, and flourishing, and finally obtained the privileges of Roman citizenship. Of the 11 divisions of Italy, as established under Augustus, it formed the last four. The Salassians, who revolted under the same reign, were nearly exterminated. The Romanization of the province was rapidly developed, and many celebrated Romans of the later period were its natives, as for instance Livy, who was born at Patavium (Padua) in 58 B. C.—Of Transalpine Gaul, upon the southern coast of which Phœnicians, Rhodians, and Phœceans had, at various remote periods, carried colonies and some rudiments of civilization, the arts of writing, mining, and working metals, the olive and the vine, the Romans first entered the S. E. angle. In 166 B. C. the Maritime Alps were first crossed by Roman legions, who defeated the tribes of the western slopes. In 154 they defended Massilia (Marseilles), a colony of Phœcæ, and herself the mother of numerous colonies, against the Ligurians. Twenty years later they fought against the Salyes, a Celto-Ligurian tribe. Soon after they founded Aquæ Sextiæ (Aix), and subdued the Allobroges, who lived between the Rhone (Rhodanus) and the Isère (Isara), and were assisted by the Arverni (121). This new course of Roman conquests was interrupted by the great Cimbro-Teutonic movement (see Cimbri), but the two victories of Marius at Aquæ Sextiæ (102) and on the Raudian fields (101), over the Teutons and Cimbri, saved both the Transalpine and Cisalpine possessions of Rome. The former, eventually extending from the Alps to the Pyrénées, and embracing the modern provinces of Dauphiny, Languedoc, Provence (from the Roman *Provincia*), Roussillon, and Nice, were called Gallia Braccata or Comata, from the long hair (*coma*) of the inhabitants. The internal development of the main parts of Transalpine Gaul, during the times when the Cisalpine country was successively Gallicized and Romanized, cannot be traced in historical records. When the Romans,

in the last period of the history of their republic, finally entered the great north-west, they found the country occupied by various tribes, ruled by nobles, priests, and chiefs or kings. Cæsar, the conqueror of the people and the historian of their last desperate struggles for independence, comprehends all of them under the general name of Gauls, dividing them, however, into the 3 large groups of Belgians, in the N. E. between the Rhine, Seine (Sequana), and Marne (Matrona); Celts, or Gauls proper, in the centre and west, between the Seine, Marne, and Garonne (Garumna); and Aquitanians, in the S. W., between the Garonne and the Pyrénées. In the first of these groups Kymric and Belgic elements seem to have prevailed, in the second Gaelic, in the third Iberic and other non-Celtic elements, though the divisions of Cæsar do not fully coincide with the lines of distinction drawn by modern ethnologists. Among the more important tribes were the Batavi, near the mouths of the Rhine; the Nervii, in the S. W. of modern Belgium; the Eburones, about Liège; the Ambiani, about Amiens; the Morini, "the remotest of men," about Boulogne; the Atrebatæ, in Artois; the Bellovacæ, about Beauvais; the Suessiones, about Soissons; the Parisii, about Paris (Lutetia); the Remi, in Champagne (Rheims); the Treveri, about Treves; the Teutonic Tribocci, Ubii, and Nemetes, on the Rhine; the Eburones, about Evreux; the Cenomani, in Maine; the Armorican Nannetes (Nantes), Veneti (Vannes), and Redones (Rennes), the chief representatives of the Kymric race, in Brittany; the Turones, in Touraine; the Andes or Andegavi, in Anjou; the Carnutes, about Chartres and Orleans; the Lingones, about Langres; the Senones, about Sens (Agendicum); the Lemovices, in Limousin; the Santones, in Saintonge; the Pictones, in Poitou; the Arverni, in Auvergne; the Helvii, in Vivarais; the Gabali, in Gévaudan; the Ædii, in the region of Autun (Bibracte); the Mandubii, about Sainte Reine and Alise (Alesia); the Insubres, in Lyonnais; the Bituriges, in earlier times a leading tribe, about Bourges (Avaricum); the Sequani, about Besançon (Vesontio); the Helvetii, in Switzerland; the Bituriges Vivisci, about Bordeaux (Burdigala); and the Tarbelli, in Béarn.—Compared with their eastern neighbors, the Germans, the Gauls had reached a certain degree of culture at the time of Cæsar's invasion. They had towns, and used the art of fortification with success; they had long known the arts of embroidering and working metals, and were regarded as the inventors of various implements of husbandry; the Armoricans possessed a navy; the Gallic country was reputed to be the richest in Europe. The Romans, however, were fully entitled to call them barbarians. Their manners were rude, their speech was rough and hardly intelligible, milk and flesh of swine were the principal aliments, their villages were adorned or rather disfigured with inhuman trophies, the treatment of captive or slain enemies was bar-

barous, bloody fights and duels were customary, hounds were used in war, polygamy was not prohibited, and females were little more than slaves; the polytheism which prevailed among the common people, especially among the Gaul, was ruder than that of Italy; the mysteries of the druids, whose influence prevailed chiefly among the Kymri, were stranger than those of the augurs, and the altars of the gods smoked with the blood of human victims. (See *DRUIDS*, and *BARD*.) The remains commemorative of Gallic culture are extremely scanty, and many a French writer of the romantic school has tried in vain to shed lustre over the life and character of the people who, with their successive conquerors, the Romans and Franks, were the ancestors of the French nation. The chief national features of resemblance are vivacity and rapidity in resolution and action, and great love of military glory. It must also be acknowledged that in the defence of their native soil and independence the Gauls of the 1st century B. C. developed the same dauntless and desperate courage and resolution which made the France of the revolution invincible. The absence, however, of national union and centralization, and the genius of a Cæsar in the camp of the enemy, led to their conquest. The details of that bloody war may be read in the "Commentaries" of the great Roman general himself. Its chief events (as far as regards Gaul) are the defeat of the Helvetians in the murderous battle near Bibracte, and the expedition against the Suevi under Ariovistus undertaken on the call of the Ædui, in 58; the conquest of Belgic Gaul in 57; the invasion of Armorica or Brittany by land and sea, the submission of Aquitania, and the reduction of the wild tribes on the N. E. coast, in 56; the sudden and successful attacks of the Eburones under Ambiorix, and their annihilation, in 53 and 52; the great rising of central Gaul under Vercingetorix, the double blockade at Alesia, and the fall of Avaricum, the last stronghold of the natives, in 52 and 51. The loss of the Gauls in these struggles, in which genius and discipline conquered unbridled and tumultuous valor, was little less than a million of men. The whole Transalpine country was divided by Augustus into 4 provinces: Gallia Narbonensis (Narbonne), the former *Provincia Romana*, Gallia Aquitania, Gallia Lugdunensis, and Gallia Belgica, to which were added later the divisions Germania Superior or Prima, and Germania Inferior or Secunda, on the Rhine. Other subsequent divisions are less important. For more than 2 centuries after its conquest by Cæsar, Gaul remained almost entirely quiet, and its Romanization progressed rapidly, the national habits and religion retiring by degrees toward the shores of the north-western sea, and eventually finding refuge in the islands beyond it. The history of the country in the times of the Roman emperors, under the later of whom it was Christianized, belongs to that of Rome. Civil wars and dissensions in the 3d

century, and later the invasions of the Alemanni, Franks, Burgundians, Visigoths, Huns, and other barbarians, brought about its decay. Clovis made it Frankish. (See *FRANCE*.)

GAUSS, KARL FRIEDRICH, a German mathematician, born in Brunswick, April 30, 1777, died in Göttingen, Feb. 23, 1855. He early displayed such remarkable capacity for mathematical calculation, that (his parents being poor) the duke of Brunswick took charge of his education. At the age of 18, while a student at Göttingen, he solved a problem which had occupied geometers from the time of Euclid, that of the division of the circle into 17 equal parts. In 1801 he published his *Disquisitiones Arithmeticae*, treating of indeterminate analysis or transcendental arithmetic, and containing, beside many new and curious theorems, a demonstration of the famous theorem of Fermat concerning triangular numbers. It gave him at once a distinguished place among scientific men. He was one of the first to calculate, by a new method, the orbit of the newly discovered planet Ceres, and afterward that of Pallas, for which he received from the French institute in 1810 the medal founded by Lalande. In 1807 he was appointed professor of mathematics and director of the new observatory at Göttingen, a position which he retained till his death. His profound works, though produced with a rapidity that astonished the savants of Europe, were elaborated with the greatest care, and many of them mark an era in the history of science. He wrote only on mathematics, but was also interested in politics and literature, loved to read the newspapers and converse on the events of the day, and is said to have been exasperated that any credit was given to the accounts of table-tippings at a time when so many efforts were made to enlighten the public by popularizing the sciences. From the year 1828 he never left Göttingen, and he did not see a locomotive till 1854. As a mathematician, he was pronounced by Laplace the greatest in Europe. Among the more important of his works are *Theoria Motus Corporum Cælestium* (Hamburg, 1809; translated into English by O. H. Davis, Boston, 1857); *Intensitas Vis Magnetica Terrestris* (Göttingen, 1838); *Dioptrische Untersuchungen* (Göttingen, 1841); and *Untersuchungen über Gegenstände der höhern Geodäsie* (Göttingen, 1844). Being appointed to measure a degree in Hanover, he rendered the most distant stations visible by means of the heliotope, an instrument of his invention for reflecting solar light; and in connection with Weber he made valuable investigations concerning terrestrial magnetism.

GAUTAMA. See *BUDDHISM* and *BUDDHA*.

GAUTIER, THÉOPHILE, a French writer, born in Tarbes, Aug. 31, 1811. He studied painting, but in 1828 gave up the brush for the pen, and published a small volume of poems, remarkable for picturesque originality. An eccentric and somewhat licentious novel, *Mlle. de Maupin*, which caused a considerable sensation was the

foundation of his literary fame. He contributed to the *Revue de Paris*, and more largely to the *Artiste*, of which he afterward became chief editor. In 1836 he was intrusted with the dramatic *feuilleton* of the *Presse*, and soon made his mark among those who are usually styled in Paris *les princes de la critique*. In 1854 he left the *Presse*, and took a similar position on the staff of the *Moniteur*. He has published a number of poems, novels, and books of travels, and has written dramas, vaudevilles, and ballets.

GAVARNI, the pseudonyme of a French caricaturist, whose real name is SULPICE PAUL CHEVALIER, born in Paris in 1801. He was at first a machinist, and commenced his artistic career by drawing theatrical costumes and fashion plates. In 1835 he began to publish an illustrated satirical paper which he called *Les gens du monde*. Many of his sketches were reproduced in the *Charivari*. A collection of his designs was published in 1845, in 4 vols., with letterpress by Balzac, Théophile Gautier, Jules Janin, &c. Two other volumes were added in 1850.

GAVAZZI, ALESSANDRO, an Italian preacher and political agitator, born in Bologna in 1809, joined the order of the Barnabites in 1825, and afterward officiated as professor of rhetoric at Naples. He was in Rome at the outbreak of the revolution in Lombardy, delivered in the Pantheon a funeral oration on those who had fallen in that struggle, and made passionate appeals in behalf of the independence of Italy. The pope appointed him almoner of the Roman legion which was despatched to Vicenza, and he was called by the people the *Pietro Eremita*, or Peter the Hermit, of the national crusade. In Venice he addressed immense crowds in St. Mark's place, and thus gained means for conducting the war. Pius IX., however, alarmed at the spread of the revolution, caused his army to return to Rome. Gavazzi repaired to Florence, and, after his expulsion from that city, to Genoa; but he was recalled to Bologna, where he was received with great enthusiasm by the people who had risen against the papal government. He was appointed by the republican government chaplain in chief of the army, and after the French occupation of Rome (1849), he found an asylum in England. He has since lectured in the United Kingdom and in the United States and Canada against the church and government of Rome. Since 1854 he has chiefly resided in London.

GAVELKIND, a tenure in England by which the estate descends, not to the eldest son, as by common law, but to all the sons, or if there be no sons, to all the brothers. The word is said by some persons to be derived from the English words "given to all the kindred;" but other derivations are suggested. It prevails throughout the English county of Kent, but is seldom met with in other counties. The best authorities, including Selden, believe that this was the general custom of England before

the Norman conquest. It is not the same with the universal tenure of this country, because here lands descend, as personals do both here and in England, to all the children, females included; and for want of them to brothers and sisters equally.

GAVIAL, or GARRHIAL, a crocodilian reptile of Asia and Africa, of the genus *gavialis* (Geoffroy), characterized by its very long, straight, and narrow jaws, somewhat enlarged at the extremity. The number of teeth is greater than in other crocodilians, being 110 to 120 in all, from 50 to 60 in each jaw; the upper mandible is not pierced for the passage of the lower teeth, but has 2 grooves in each side for the reception of the 1st and 4th under teeth, the anterior being deep and in the front of the jaw; the 5 or 6 anterior pairs, both above and below, are larger than the rest of the teeth, the largest being the 1st, 8d, and 4th above, and the 1st, 2d, and 4th below, and all are of a conical form, slightly depressed from before backward. The division of the lower jaw into 2 branches begins about the 22d tooth of the series of 26. The bony opening of the nasal fossæ is triangular, and this is closed in the males by a large oval cartilaginous sac, whose cavity is supposed to serve as a reservoir of air when the animal plunges under water. There are 5 toes on the fore paws, and 4 on the hind, the middle 3 of the former being united at their base by a very short web, and the external 3 of the latter by a thicker and more extensive membrane covered with small granular scales; the nails are feebly curved. The nuchal plates are 2, of large size and ridged, and of oval form, sometimes with a small plate on each side of them; the cervical plates, 4 pairs, extend from the middle third of the neck to the dorsal covering in a longitudinal band, and are ridged on their median line; the upper part of the trunk is protected by 4 longitudinal series of ridged quadrilateral scales, each containing about 18, and the sides of the neck and flanks by flat smooth scales of medium size; the tail has from 34 to 40 circles of scales, becoming crested about the 6th or 7th on each side, the double portion becoming single and the highest near the middle of the length; the under surface of the body is covered by about 60 transverse rows of smooth, oblong, quadrilateral scales, each pierced on the posterior border by a small opening. The scales of the limbs are rhomboidal, and on the posterior ones from the ham to the little toe furnished with a serrated crest. The common species, the gavial of the Ganges (*G. Gangeticus*, Geoff.), is of a deep sea-green color above, with numerous irregular brown spots, smallest and thickest about the jaws, and below pale yellowish white; the young have the back and limbs banded with black. It attains a length of over 20 feet, though the specimens usually seen are considerably smaller than this; in the adult the head is a little less than $\frac{1}{3}$, and the tail about $\frac{1}{4}$ of the total length of the animal. Though most common in the river Ganges, it is found in other rivers of Asia; and other species

have been described from Africa. Notwithstanding its large size and numerous teeth, the gavial feeds on fishes and small prey; the narrowness and feebleness of the jaws do not enable it to seize large land animals, like the wide and stronger jawed crocodile and alligator. The general structure and habits of the gavial do not differ essentially from those of the CROCODILE, to which article the reader is referred.—The fossil crocodiles which existed toward the end of the secondary epoch all had the elongated jaws of the gavial, the true crocodiles not appearing until the tertiary period at the same time with their mammalian prey. The *orocordilus prius* of Sömmerring, the *teleosaurus* and the *stenosaurus* of Geoffroy, all had the cranial characters of the gavial. This reptile, though now confined to the warmest regions of the earth, in former geological ages lived with alligators and crocodiles in northern and now temperate Europe.

GAY, CLAUDE, a French traveller and botanist, born in Draguignan, March 18, 1800. In 1828 he went to Chili to study the botany, zoology, geology, and meteorology of that country, extending his observations through its almost unexplored regions, and receiving great encouragement from its government. With the exception of a few months in 1832, when he returned to France for meteorological instruments, he remained in Chili until 1842. After his return to Paris in that year he published at the expense of the Chilean government, and with the aid of several assistants, especially in the historical part, his *Historia física y política de Chile* (Paris, 1843-'51), in 24 vols., of which 6 are devoted to the history, 2 to the historical documents, 8 to the botany, and 8 to the zoology of the country, beside an atlas in 2 large 4to. vols., composed of 315 plates. This work is written entirely in Spanish, and is considered second only in authority and value to those of Humboldt on South America. M. Gay has also made scientific explorations of Peru, Brazil, and Buenos Ayres, and has travelled in Russia, Asia Minor, Greece, and Morocco. He is the author of a number of special treatises on botanical subjects.

GAY, DELPHINE. See GIRARDIN.

GAY, EBENEZER, D.D., an American clergyman, born in Dedham, Mass., Aug. 26, 1696, was graduated at Harvard college in 1714, and was settled over the church at Hingham, Mass., in 1718, its third pastor since the settlement of the town in 1635, and of which he remained the clergyman 69 years and 9 months, till his death in 1787. On his 85th birthday he preached a sermon from the text: "Lo, I am this day fourscore and five years old," which, under the title of "The Old Man's Calendar," has been frequently republished in America, went through several editions in England, and was translated into one or two of the continental languages of Europe. Many other of his sermons were published, and had a high reputation in their day. He was a man of great learning, and

was known for his wit as well as for his virtues. In his theology he was liberal, though he was a tory in principles, and suffered some persecution from his own parishioners during the war of the revolution. Ex-president John Adams said, on the first distinctive announcement of Unitarianism in this country, that he had heard the doctrine from Dr. Gay long before. He married Jerusha Bradford, a granddaughter of Gov. Bradford of Plymouth colony, by whom he had a large family. He died when 90 years of age, on Sunday, when about to enter the pulpit for the services of the day.—MARTIN, an American physician, great-grandson of the preceding, born in Boston, Feb. 16, 1803, died there, Jan. 12, 1850, was graduated at Cambridge in the class of 1823. He had a high reputation as an analytical chemist, and his testimony was of great weight in courts of justice in cases of death by poisoning, at a time when but little attention had been given to this branch of medical jurisprudence.—WINKSWORTH ALLAN, an American artist, brother of the preceding, born in Hingham, Mass., Aug. 18, 1821. At an early age he became a pupil of Mr. Weir, professor of drawing at the military academy at West Point, with whom he remained several years. Subsequently he went to Europe, and passed 5 years there in study, a part of the time under Troyon in Paris. He paints exclusively in landscape, and his style is that known as the modern French. "A Scene in the White Mountains," a picture painted for the Boston Athenæum, is a good specimen of his method of treatment of mountain scenery. Some of his best works depict that region. But he has also painted views of Nantasket beach and rocks, which have attracted much attention, and some critics have pronounced coast scenery to be his proper speciality.

GAY, JOHN, an English poet, born near Torrington, Devonshire, in 1683, died in London, Dec. 4, 1732. He was of an ancient but reduced family, and after receiving an elementary education at the grammar school of Barnstaple, was apprenticed to a silk mercer in London, but soon abandoned this business for literary pursuits. In 1711 he produced his poem "Rural Sports," which he dedicated to Pope, and a life-long friendship sprung up between the two poets. In the following year he became secretary to the duchess of Monmouth. His next work, "The Shepherd's Week," was written to throw ridicule on the pastorals of Ambrose Philips, and met with great success. In 1713 he brought out a comedy called "The Wife of Bath," which was acted only 8 nights. In 1714 he accompanied the British ambassador, Lord Clarendon, to Hanover as secretary. On the death of Queen Anne, however, he was dismissed from office, and driven once more to use his pen as a means of support. Soon after returning to England he produced a drama entitled "What d'ye Call It?" which was so well received that he made another attempt of a similar nature, in which he is said to have

been assisted by Pope and Arbuthnot; but owing to its personality and indelicacy, the "Three Hours After Marriage" proved a decided failure, and involved its author for a time in disgrace. In 1727 his celebrated "Beggars' Opera" was brought on the stage, and was represented for 62 successive nights, 4 of which were for his own benefit, and yielded him nearly £700. This piece was followed by another opera entitled "Polly;" but the lord chamberlain forbade its representation, and Gay was constrained to publish it by subscription, by which he realized £1,100 or £1,200. The most important of his other works are "Trivia, or the Art of Walking the Streets of London," and his "Fables," which are among the best of their kind in the language. Of his minor poems, the ballads of "Black-eyed Susan" and "Twas when the Sea was Roaring" are the most popular. Gay was at one time rich, but he lost nearly all his property by the bursting of the South sea bubble. His latter days were spent in the house of the duke of Queensberry. The prominent characteristics of his poetry are wit, simplicity, and sweetness. The best edition of his works is that of W. Coxe (London, 1796); the best edition of his "Fables," that of O. F. Owen (London, 1856).

GAY, MARIE FRANÇOISE SOPHIE, a French novelist, born in Paris, July 1, 1776, died March 5, 1852. She was the daughter of a French financier named Nichault de la Valette, and was married in 1793 to M. Liottier, from whom she was divorced in 1799. She then became the wife of M. Gay, receiver-general of finance in the department of La Roër, under the empire. She resided at Aix la Chapelle, where she formed a friendship with Pauline Bonaparte. As early as 1802 she had published anonymously in the *Journal de Paris* an article upon Mme. de Staël, and in the same year appeared her first novel, *Laure d'Estell*, which had a moderate success. She now laid aside her pen for a time, and in the fashionable society which gathered at her house was distinguished for wit and agreeable manners. In 1813 she published *Léonie de Montbreuse*, which is considered one of her best novels. This was succeeded in 1815 by *Anatole*, which narrates the loves of a deaf-mute, and in 1818 by *Les malheurs d'un amant heureux*, a very lively picture of manners during the empire. She continued to produce novels and books of various sorts until a few years before her death, among them *Les souvenirs d'une vieille femme*, a piquant abstract of her personal memoirs. She wrote for the stage, but not with marked success.

GAY-LUSSAC, JOSEPH LOUIS, a French chemist and physicist, born in St. Leonard, Limousin, Dec. 6, 1778, died in Paris, May 9, 1850. He was the eldest of 5 children, 3 daughters and 2 sons, of Antoine Gay, judge of that portion of St. Leonard called Pont de Noblat. The father adopted the additional name Lussac from that of a neighboring village, of which he was

principal proprietor. In the troubled times of the revolution the chief portion of his estate was confiscated, the father hardly escaping even with his life. In 1794 the eldest son was sent to Paris to complete his education. He soon displayed great mathematical talents, and in Dec. 1797, entered the polytechnic school, then called *l'école centrale des travaux publics*. From this he passed to the school of roads and bridges, where he became the favorite pupil of Berthollet, who soon recognized and encouraged his talent for original investigation, and placed him with his own son at the government chemical works at Arcueil, where the new bleaching process by chlorine was undergoing a course of experimental investigation. After this he returned to the polytechnic school as tutor. In 1802 he read before the academy a paper on the precipitation of the metallic oxides. In 1804 the institute of France, in order to determine if possible the question as to the diminution of the magnetic force at great heights above the surface, commissioned Gay-Lussac and Biot to conduct the investigations for this purpose; and at the request of Laplace the small balloon was furnished them which had been used in the expedition in Egypt. Ascending at 10 o'clock A. M., Aug. 24, they endeavored at an elevation of 4,000 metres to solve the problem by observing the time of duration of the oscillations of a needle suspended horizontally; the longer the vibrations the less of course being the force which brings back the needle. The rotation of the balloon itself seriously interfered with the observation, and the results were not deemed satisfactory. On Sept. 16 Gay-Lussac made another ascent alone at 9 h. 40 m. A. M., rising to the extraordinary height of 7,016 metres, or about 23,000 feet, above the level of the sea; and at 8 h. 45 m. he descended, landing between Rouen and Dieppe, 40 leagues from Paris. The results of his observations made important additions to our knowledge of the composition of the atmosphere, and its varying conditions at different heights. (See AEROSTATION.) Alexander von Humboldt investigated with him the qualities of the air brought down, and in their joint paper to the academy, Oct. 1, 1804, appeared the first announcement of the union of oxygen and hydrogen to form water in the simple proportion of 100 parts by measure of the former to 200 parts of the latter. In 1805 he visited Vesuvius with Humboldt and Leopold von Buch, and happily the volcano at the time of their observations suddenly became active. Gay-Lussac considered that volcanic phenomena are due not to the central heat of the globe, but to the action of sea water flowing in upon combustible matters. He adopted Von Buch's views as to the uplifting bodily of volcanoes. At Naples he showed the difference in the composition of the air contained in sea water and that of the atmosphere, the former consisting of more than 80 parts of oxygen in 100, and the latter of only 21. His observations upon the irregularities of the mag-

netic needle, made during his travels in Italy, and thence into Germany with Humboldt, were published in vol. i. of the *Mémoires de la société d'Arcueil*, of which society Gay-Lussac was one of the earliest and most active members. In 1807 he directed his studies to the expansion of the air and gases under increased temperatures, and established the law that when free from moisture they all dilate uniformly and to equal amounts for equal increments of temperature—at least when between 0° C. and 100° C. He also showed that the gases combine in simple proportions of their volumes, and that the contraction sometimes experienced by a compound of several is always an exact simple fraction, as $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, of their joint bulk. His researches were in the same field with those in which Dalton also was engaged, and his conclusions were in general confirmatory of those of the English chemist, and served to extend the application of the newly devised atomic theory to gaseous bodies. The discoveries of Davy in decomposing by the voltaic pile compounds before regarded as simple, excited much interest in France; and Gay-Lussac and Thénard were appointed by Napoleon to pursue this class of researches. In the course of their experiments, on June 8, 1808, Gay-Lussac, by the accidental projection of a piece of potassium, lost for some time the use of his eyes. The results of their investigations were published in 1811 in 2 vols. 8vo., entitled *Recherches physico-chimiques*. By means of the great battery provided by the institute they prepared potassium and sodium in larger quantities than these elements had been obtained by Davy. They also developed the compound character of boracic and fluoric acids, introduced new methods of analyzing organic substances by their combustion with chlorate of potash, and elucidated the composition of many of these compounds. In the *Annales de chimie et de physique*, which Gay-Lussac edited together with Arago, and in other scientific journals of the day, were published many papers presenting other original researches of importance by the former, as upon the newly discovered elements iodine and cyanogen, on Prussian blue, on chloric and hydrosulphuric acids, on capillary attraction, and many other subjects. In 1816 he invented the siphon barometer, since modified by Bunten, by whose name it is best known. He also invented instruments for estimating the quantities of alcohol, chlorine, and alkali present in solutions, known severally as the alcoholometer, chlorometer, and alkalimeter. In 1832 he gave up the professorship at the Sorbonne, to which he had been appointed in 1809, and accepted that of general chemistry at the *jardin des plantes*. As an expounder of science he was distinguished for the clearness of his explanations. In 1831 he was chosen by the electors of his native town member of the chamber of deputies; in 1837 he was reelected, and in 1839 he was made a peer of France.

GAYA, a town of British India, in the dis-

trict of Bahar, presidency of Bengal, 265 m. N. W. from Calcutta; pop. 43,451. It consists of two parts, the old town, in which the Brahmins reside, and the new town, called Sahibgunge, from having been chiefly laid out by the British, inhabited by the secular population and Europeans. Gaya proper, or the old town, is well built in a peculiar style of architecture, but the streets are narrow, filthy, and hardly passable. There are numerous shrines and places of pilgrimage, visited by devotees from all parts of India. The Phalgu, a tributary of the Ganges, flows through the town, and is deemed a sacred stream. The most revered structure here is the temple of Vishnu, erected by a Mahratta princess, 82 feet in length, and crowned by an octagonal pyramid over 100 feet high. In the immediate vicinity are the remarkable ruins of Buddha-Gaya, supposed to have been the scene of the avatar of Buddha or Gautama; whence the sanctity of the existing town is derived, though it now contains no worshippers of Buddha. Sahibgunge, or the new town, has wide and straight streets, with rows of trees and foot walks on each side; but its houses for the most part are mere mud-built huts, and there are no public edifices, save a hospital for invalid pilgrims. On an area between the two towns stands the British civil establishment.

GAYANGOS, PASCUAL DE, a Spanish orientalist, professor of Arabic in the university of Madrid, born June 21, 1809. He studied at Paris under Silvestre de Sacy, travelled through northern Africa in 1828, married an English lady at Algiers, and was from 1831 to 1836 interpreter to the French ministry of foreign affairs. He afterward resided several years in England, and has published his most important works in the English language. His "History of the Mohammedan Dynasties of Spain," translated from the text of Al Makkari, with learned notes, appeared in London in 1840-'43, in 2 vols. 4to. Prescott, who was greatly indebted to Gayangos for assistance in collecting materials for his historical works, calls this work "a treasure of oriental learning." In 1843 he was recalled to Madrid to fill the professorship which he still holds. He has made in conjunction with H. Vedia a Spanish translation of Ticknor's "History of Spanish Literature," to which he added copious notes (Madrid, 1851-'6).

GAYARRÉ, CHARLES A. ARTHUR, an American historian, born in Louisiana, Jan. 9, 1805. He belongs to one of the most ancient families in the state, some of his ancestors having assisted in the foundation of the French colony on the banks of the Mississippi; he was educated at the college of New Orleans, and gave early evidence of talent as a forcible writer. In 1825, the draft of a criminal code having been laid before the legislature by Edward Livingston, young Gayarré published a pamphlet in which some of its provisions were ably canvassed; and such was the sensation caused by this youthful performance that the adoption of

the code was indefinitely postponed by the legislature. He then repaired to Philadelphia, and studied law under the direction of William Rawle; he was admitted to the bar in 1829, and a few months later returned to his native state. An *Essai historique sur la Louisiane* (2 vols. 12mo.), which he published at that time, attracted attention; and he was soon elected by an almost unanimous vote a member of the state legislature for the city of New Orleans, and was chosen to write the congratulatory address which that body sent to France on occasion of the revolution of July, 1830. The next year he was appointed deputy attorney-general of the state, and in 1833 presiding judge of the city court of New Orleans. In 1835, although he had but just reached the constitutional age, the legislature elected him to the U. S. senate. Impaired health prevented his taking his seat, and by medical advice he went to Europe, where he remained for nearly 8 years. In 1844 he again entered the state legislature, and was re-elected in 1846. Gov. Johnson appointed him secretary of state, and Gov. Walker, who succeeded Gov. Johnson, insisted upon his retaining the office. During his 7 years of official service as secretary, the banks were kept in a healthy condition, public education was fostered, and he succeeded in establishing a respectable state library, which now contains many valuable documents collected in the archives of France and Spain. At the same time his leisure was devoted to historical studies. He has published in French an *Histoire de la Louisiane* (2 vols. 8vo., New Orleans, 1847); and in English, the "Romance of the History of Louisiana" (12mo., New York, 1848), a lively and poetical introduction to a new history of the state; "Louisiana, its Colonial History and Romance" (8vo., New York, 1851); "Louisiana, its History as a French Colony" (2 vols. 8vo., New York, 1851-2); "History of the Spanish Domination in Louisiana, from 1769 to Dec. 1803" (New York, 1854). Mr. Gayarré has also published two lectures "On the Influence of the Mechanic Arts," delivered in New Orleans; a satirical drama, the "School for Politics;" and an "Address to the People of the State on the late Frauds perpetrated at the Election held on the 7th of November, 1853, in the City of New Orleans." After this publication he left the democratic party to join the Americans, but he has since withdrawn from them, and now lives retired from political life.

GAZA (Arab. *Ghazze* or *Ghuzze*), a town of Syria, built partly on a steep hill, partly on the plain below, on the road leading to Egypt, between the Mediterranean and the desert; pop. about 16,000, of whom 200 or 300 are Christians. It is situated about 3 m. from the sea, in the neighborhood of rich gardens, is not fortified, and consists partly of mud cottages, partly of ruinous stone buildings, which are occupied by the government and chief citizens. It is an important entrepot for the caravan traffic between Egypt and Syria. It has few rel-

ics of antiquity, and its only interesting edifice is a mosque which was originally a Christian church, founded, according to tradition, by the empress Helena. The ancient city of Gaza, which some suppose to have stood nearer the sea than the present town, is known in the Bible as the most southern of the 5 confederate cities of the Philistines, and is often mentioned, as for instance in the history of Samson. Its Hebrew name signifies "strong." On the conquest and division of Palestine by the Israelites, it was allotted to the tribe of Judah, which conquered it, but lost it again. It shared in the wars of the Philistines with the Hebrews. Having become a possession of Persia, it was taken after an obstinate siege by Alexander the Great (332 B. C.); nearly all its inhabitants perished during the assault, and its commander Batia, at the conqueror's order, was dragged around the walls at the wheels of a chariot. After Alexander's death it was taken by Antigonus, and witnessed the defeat of Demetrius Poliorcetes by Ptolemy (312). After the restoration of Jewish independence by the Maccabees, it was several times assaulted, besieged, and taken by the princes of that house. The Romans ceded it to Herod the Great. Under Nero it was taken by the revolted Jews. Constantine restored its ancient splendor, made it a bishopric, and gave it the name of Constantia, with various privileges. These were abolished by Julian the Apostate, and restored by his Christian successors. The Arabs took it (634), immediately after the death of Mohammed. The crusaders captured it in 1100, and from them it was wrested by Saladin. In the 13th century it witnessed the double defeat of the Christian armies by the Khovaresmians and of the emir of Damascus by the Egyptians, and in 1556 that of the Mamelukes by the Turks. In 1771 it was seized by the revolted Ali Bey, and in 1799 by the French under Kleber.—Another Gaza (correctly, Gazaca) was in Media Atropatene, a summer residence of the Median kings. Ruins of it are seen between Miana and Tabreez.

GAZA, THEODORE, one of those learned Greeks who contributed to the revival of letters in Italy, born in Thessalonica about 1400, died in Abruzzo in 1478. After the capture of his native town by the Turks in 1480 he fled to Italy, where he introduced a more exact knowledge than had before existed of the two principal philosophers of antiquity. He was a peripatetic, and devoted himself especially to translating into Latin the works of Aristotle. After assisting at the council of Florence in 1489, he taught Greek at Ferrara by the invitation of the duke, and founded there an academy. In 1455 he was called by Pope Nicholas V. to Rome, where he translated the "Problems" of Aristotle, and other Greek works. He afterward lived at Naples under the patronage of Alfonso the Magnanimous, and at Rome under that of Cardinal Bessarion. His translations were admired by the scholars of the 15th and 16th centuries.

GAZEL, or GHAZEL, a kind of lyric poem, consisting of from 5 to 17 stanzas of 2 lines each, all the second lines of which rhyme together. It is a favorite form in the poetry of the Turks and the Persians, and may be called the sonnet of the East. The last couplet always contains the real or assumed name of the author. The subjects treated in the gazel are either erotic and bacchanalian, or allegorical and mystical. Hafiz excels in this form of the lyric, and imitations of it have been made in German by Platen, Rückert, and others.

GAZELLE, the type of a group of the antelope family (see ANTELOPE), of beautiful form, small size, graceful carriage, and an expression of mildness and tenderness which has made it the emblem of womanly beauty in the amatory poetry of the eastern nations. Both sexes are provided with horns, nearly over the orbits, annulated and striated, nearly vertical, and bending outward and at the top inward in a lyrate form, and of a black color; the shape of the ancient lyre is said to have originated from using in its construction the horns and the frontal bone of antelopes, the strings being passed from a cross bar at their tips to a second fastened across the orbits; the bony core of the horn is solid. They have a small lachrymal sinus, inguinal pores, generally tufts upon the knees, a short dark-tufted tail, and 2 or 4 mammae; the darker color of the sides is separated from the white of the abdomen by a very dark band; the eyes are prominent, dark colored, with a soft and gentle expression; the nose is ovine. They are gregarious, inhabiting the open and barren plains of northern Africa and western Asia, shy and difficult of approach, and extremely swift. The common gazelle, or Barbary antelope (*gazella dorcas*, H. Smith), the *gazel* of the Arabs, is generally regarded as the *dorcas* of Ælian, and the *zebi* of the Scriptures. It is a little less than the roebuck in size, with round, black, lyrate horns, about 18 inches long, with 12 or 13 bars, and sharp points turned forward; the general color is pale fulvous, extending down the front and outside of the limbs; the lips, nose, buttocks, under parts, and inside of legs white; a rufous tint on the forehead, blackish in the middle, and white and black streaks on the nose; eyes large, black, and lustrous. The horns in the female are more slender, and the points are turned inward; the mammae are two. This species seems to be confined to the N. side of the Atlas mountains, Egypt, Abyssinia, Syria, Arabia, and S. Persia. They feed generally at dawn and at evening, approaching water, it is said, only once in 24 hours; they are hunted in various ways, and their flesh is excellent; they furnish food to great numbers of carnivorous animals. The *kud* (*G. kudu*, H. Smith) is by some considered a mere variety of the gazelle; it is about the same size, but the head is longer, the horns more robust and longer, the orbits larger, the eyes fuller, and the geographical distribution to the south of the Atlas; the habits and general

disposition of the colors are the same as in the gazelle. The *corinna* of central Africa, described by Adanson, appears to be one or the other of the preceding species. Other gazelles are the *m'hor* of Mr. Bennett, and the *nanguer* of F. Cuvier, which are also supposed by many to be varieties of the *G. dorcas*. Sömmering's gazelle (*G. Sömmeringii*, Rüpp) is a very beautiful and delicate creature, about 2½ feet high at the shoulder; the color above is a reddish-gray isabella color, the buttocks, lower parts, and inside of the limbs white, and the median line of the forehead to the nose brownish black; it inhabits N. E. Africa.

GAZETTEER, a cyclopædia of geography. Stephen of Byzantium (probably in the 6th century) wrote a work of this kind, entitled *Ethnica*, of which only an epitome remains. The earliest noticeable modern gazetteers were by Ferrari (Milan, 1627), Baudrand (Paris, 1681-'2), Laurence Echard (London, 1708-'4), and Thomas Cornelle (Paris, 1708), which were all superseded by that of La Martinière (10 vols., the Hague, 1726-'30). An abridgment of this was made by Ladvocat (1747), under the assumed name of Vosgien. Of more recent gazetteers, the principal are those of Hübner, *Staats-, Zeitungs-, &c., Lexikon* (1804; revised and enlarged by Rüdor, 1824); Hassel, *Allgemeines geographisch-statistisches Lexikon* (1817); Stein, *Zeitungs-, Post- und Comtoir-Lexikon* (1818); Möller, *Geographisch-statistisches Lexikon* (1847); Ritter, *Geographisch-statistisches Lexikon* (4th ed., Leipsic, 1855); Hoffmann, *Encyclopædie der Erd-, Völker- und Staatenkunde* (Leipsic, 1855 et seq.); Kramers, *Geographisch Woordenboek* (Gouda, 1858); Castro, *Gran dizionario geografico* (Milan, 1855); *Dictionnaire géographique universel, par une société de géographes* (10 vols., Paris, 1828-'38); Bescherelle, *Grand dictionnaire de géographie universelle, ancienne et moderne* (4 vols., Paris, 1856-'7); J. R. McCulloch, "Geographical Dictionary" (2 vols., new ed., London, 1851; a New York edition, under the care of D. Haskel, had appeared in 1848); A. K. Johnston, "Dictionary of Geography" (London, 1851, 2d ed. 1855); W. G. Blackie, the "Imperial Gazetteer" (2 vols., Glasgow, 1855); the "Gazetteer of the World," published by Fullarton and co. (7 vols., Edinburgh, 1856); J. E. Worcester, "Universal Gazetteer" (2d ed., Boston, 1828); J. C. Smith, "Harper's Statistical Gazetteer of the World," (New York, 1855); J. Thomas and T. Baldwin, "Lippincott's Complete Pronouncing Gazetteer of the World" (Philadelphia, 1856), and "Gazetteer of the United States" (Philadelphia, 1854); and R. H. Fisher, "Statistical Gazetteer of the United States" (New York, 1858).

GEAUGA, a N. E. co. of Ohio, drained by the sources of Cuyahoga, Grand, and Chagrin rivers; area, about 480 sq. m.; pop. in 1850, 17,827. It has an undulating surface, admirably adapted to pasturage. Sandstone and iron are abundant. The county produced in 1858 217,144 bushels of Indian corn, and 48,322 of

wheat. In 1850 there were 6 corn and flour mills, 6 saw mills, 2 woollen factories, 4 tanneries, 1 iron foundry, 2 newspaper offices, 40 churches, and 4,386 pupils attending public schools. Capital, Chardon.

GEBER, ABOU MOUSSAH DJAFAR AL SOFI, founder of the school of Arabian chemists in the 9th century A. D., born in Thus, Persia, or, according to Abulfeda, in Harran, Mesopotamia. He is reckoned by Oardan as one of the 12 subtlest geniuses of the world, and his authority was unrivalled among the alchemists of the middle ages. His works, only fragments of which remain, contain the germs of the belief in the transmutation of metals, and in the universal elixir, which he thought to be a solution of gold. They also contain curious and still useful details concerning the nature, fusion, purification, and malleability of metals. They have all been translated into Latin (Dantzig, 1682), and into English by Russell (London, 1678).

GECKO, a name applied to a family of nocturnal lizards (*ascalabota* of Duméril and Bibron), numerous in species, living in warm climates, and presenting characters of form, structure, and habits which make the group as distinct as that of the crocodiles or chameleons. Their size is small; the head wide, flattened, covered with scales, with marginal scutes at each jaw; the neck short; the body depressed, stout, thickest in the middle, without crest on the back, generally covered with small imbricated scales and scattered tubercles, smallest on the back; the tail moderate; the feet 5-toed, the thumb often very short, and the other fingers equal, flattened below and lobed at the end; the tongue is fleshy, short, slightly protractile, free and scarcely emarginate at the tip; the eyes very large, covered as in serpents by a transparent immovable lid, behind which these organs have free motion; the pupil vertical, and often linear as in nocturnal animals generally; the opening of the ear is distinct, and the tympanum depressed; there are no teeth on the palate, those of the jaws thin, entire, numerous, with cutting edges, and adhering to the internal margin; femoral pores occasionally present, but usually absent; beside the leaf-like expansion at the end of the toes, nails are generally present, capable of retraction, as in the cats, the latter favoring their progression in climbing on smooth surfaces. The tail is shorter than in ordinary lizards, and the flatness and width of the head give them somewhat the aspect of salamanders; the mouth is deeply cleft, and the widely expanded jaws may be kept open for a long time, the cavity of the mouth being shut off from the throat by the application of the base of the tongue to the posterior part of the palate; from the shortness of the robust legs, the abdomen touches the ground in walking. This reptile is mentioned by Aristotle, and the modern name gecko is derived from the sound made by some of the Indian species, resembling the click of the hostler urging on his horses, and was first given by Laurenti; this

genus was the *ascalabotes* of Aristotle, the *stellio* of Pliny, and the *tarentola* of the ancient Italians. Their colors are generally gray or yellowish, but some have brighter tints which can be varied like those of the chameleon, probably by the same changes in the reflecting surface of the integuments; the sides of the body, limbs, and tail are sometimes fringed with membranes. In many species there is a line of pores along and under the thighs, from which a fatty moisture distils; some species of a genus will have these, and others not, and sometimes one sex only will be destitute of them. The tail, as in salamanders, is ruptured with facility, and is reproduced readily, often in a deformed manner. Their food consists of larvæ and insects, which they pursue into their leafy retreats; the imbricated plates on the bottom of their feet, like those of the tree frog and flies, enable them to climb smooth walls and similar surfaces, and to adhere to them with the back downward; by means of their sharp, curved, retractile claws, they can ascend trees and rough objects with ease and rapidity; from the quickness of their movements, their suddenly becoming motionless, and remaining so for a long time, and their resemblance to the colors of the substances on which they are placed; they are difficult to obtain, and not easy even to see; they hunt for food both by day and night; the same qualities which fit them for the pursuit of living prey enable them to escape their bird enemies. These reptiles are very generally objects of horror and repugnance, from the prevalent but erroneous idea that they exude a poison so powerful and subtle that their touch, a drop of their saliva, or a scratch with their nails, will produce leprosy and other cutaneous diseases, often ending fatally. They like to approach human habitations, as there they find in greatest abundance their insect food; their ill-shaped body, smooth or spiny, dull colors, large head, their enormous staring eyes, rapid and silent motions, and familiarity in houses, render them very disagreeable, but by no means dangerous inmates. Found in all warm climates, they are very uncommon in Europe (2 or 3 species), and most abundant in Asia, America, and Africa, and the Pacific islands are well supplied with them. They have been divided into genera according to the form and structure of their toes; but these generic characters in a family so nearly alike in its members are very unsatisfactory, and great and unnecessary multiplication of genera has been the result of the labors of various systematists. The arrangement of Duméril and Bibron, which differs but little from that proposed by Cuvier in 1829, is as follows: 1. *Platydaitylus* (Dum. and Bibr.), with toes enlarged for their whole length, with finely plicated strim beneath; of those species having the feet cloven, some have all the toes unarmed, others all unguiculate, others with the thumb only or with the 2d and 3d fingers unarmed; of those with palmated feet the fingers are either all unguiculate

lated, or the thumb alone is unarmed; there are about 20 species, of which the varieties have been made into genera by Fitzinger, Wiegmann, Kuhl, and others. 2. *Hemidactylus* (Ouv.), with the toes widened only at the base into an oval disk striated beneath; about 15 species. 3. *Ptyodactylus* (Ouv.), with the toes enlarged at the extremity into a cleft oval disk, striated below like a fan, and all armed with claws; destitute of femoral pores; 4 described species. 4. *Phyllodactylus* (Gray), with the terminal disk as in the last genus, except that 2 plates take the place of the fan-like stris; 8 species. 5. *Sphaerodactylus* (Ouv.), small species, with the toes ending in a single, simple, smooth cushion; nails absent, as well as femoral pores; 3 species. 6. *Gymnodactylus* (Spir), with toes not widened, but striated beneath; 12 species. 7. *Stenodactylus* (Fitz.), with simple toes, granulated below, and all provided with nails; with a single species.—As specimens of this animal the following may be mentioned: The eyed gecko (*Pl. ocellatus*, Oppel.), from southern Africa, is one of the smallest species, being only $2\frac{1}{2}$ inches long, of which the head is $\frac{1}{4}$ and the body $\frac{3}{4}$; the color above is brown with white spots, beneath white, spotted with black on the throat; it is called *geitje* by the natives. The cepedian gecko (*Pl. cepedianus*, Ouv.), from Madagascar and Mauritius, is about 7 inches long, of a rose color marbled with blue; the thumb of the fore foot is a short stump. The smooth gecko (*Pl. theconyx*, Dum. and Bibr.), from the West Indies and South America, is about 5 inches long, has very fine scales, and is gray marbled with brown. The *Pl. Seychellensis* (Dum. and Bibr.), of a fulvous color, is 10 inches long. The wall gecko (*Pl. muralis*, Dum. and Bibr.; *Pl. sacetanus*, Aldrov.) is 6 inches long, of a grayish color, the upper part of the body and head rough; this species occurs all around the Mediterranean, and conceals itself in walls and stone heaps, delighting to cover itself with dirt and filth; it likes the heat of the sun, and though beneficial in houses by destroying insects and vermin, is generally feared and persecuted, like the toad and other useful creatures. The common gecko (*Pl. guttatus*, Ouv.) of the continent of Asia and its archipelago is 11 inches long, of which the tail is about half; the general color is dark gray, with whitish spots. A common gecko in the walls of houses in the West Indies is the *H. mabouia* (Ouv.), about 5 inches long, of a grayish color marbled with brown, with the posterior half of the tail ringed with black. The house gecko (*Pt. Hasselquistii*, Dum. and Bibr.), found in Egypt, Arabia, and countries bordering on the eastern part of the Mediterranean, is about $5\frac{1}{2}$ inches long, of a reddish gray color, spotted with white and pale brown, and whitish below; it is common in the damp and gloomy parts of houses, and is called at Cairo "father of leprosy," from the belief that it communicates this disease to persons who partake of food over which this animal has walked the poison being supposed to ex-

ude from the lobes of the toes. The truth is, that neither its bite nor any of its secretions are hurtful to man or beast; cats pursue it and eat it eagerly; the Egyptians are said to keep it from their kitchens by large quantities of garlic. The fringed gecko (*Pt. fimbriatus*, Ouv.), from Madagascar, attains a length of 12 inches. The spitting gecko (*Sph. sputator*, Ouv.), from St. Domingo and the West Indies, is a little more than 2 inches long, banded with black and white; it receives its name from its supposed habit of ejecting its saliva when irritated, causing swelling and inflammation of the parts which it touches; this is a mere fable. The flat-tailed gecko (*G. phyllurus*, Dum. and Bibr.) has the tail flattened like a leaf, and the upper part of the body rough with spines; it is a native of Australia, and is about 9 inches long, dark gray marbled with blackish above, and whitish beneath.

GED, WILLIAM, a Scottish mechanic, and the inventor of stereotyping, born in Edinburgh about 1700, died Oct. 19, 1749. He was originally a goldsmith in his native city, and is said to have first attempted stereotyping in 1725. In 1729 he entered into partnership with William Fenner, a London stationer, in order to carry his invention into regular practice, Fenner advancing the necessary capital on condition of receiving half the profits. Other partners subsequently joined the firm. In 1730 the company contracted with the university of Cambridge for the printing of Bibles and prayer books by stereotype, and invested a large sum of money in the speculation; but when only two prayer books were finished the contract had to be surrendered, owing, as Ged alleged, to the malignant mismanagement of the pressmen, who were hostile to the innovation, and the disreputable conduct of some of his associates. In 1738 he returned to Edinburgh, where in 1736 he completed an edition of Sallust, which was not published till 1744, and was inaccurately executed. At the time of his death Ged was about to form a partnership in London with his son James for the purpose of attempting once more to test the value of his invention.

GEDDES, ALEXANDER, a Scotch Roman Catholic ecclesiastic, born in Arradowl, Banffshire, Sept. 4, 1737, died in London, Feb. 26, 1802. He was educated at the Scotch college in Paris, where he distinguished himself as a theologian and linguist. In 1769 he was appointed pastor of a Catholic congregation at Anchinhalrig in his native county. In 1780 he removed to London with the intention of commencing a new translation of the Bible for the use of English Catholics; and under the patronage of Lord Petre, who allowed him £200 a year, and provided him with all the necessary authorities, he applied himself to his work. His original design was to make the Vulgate the basis of his translation, but he soon abandoned this idea, and substituted the Hebrew and Greek versions in its stead. The 1st and 2d volumes of this translation appeared in 1792 and 1793; the 3d,

which was merely a commentary on the Penta-teuch, in 1800; the rest of the work was never published. This translation is a tolerable performance, although the commentary is remarkable for the superficial and frivolous tone in which it advances rationalistic ideas. Immediately after the publication of his commentary, the reading of his work was forbidden to the faithful, and the author was deposed from the priesthood. A life of Geddes, containing a catalogue of his works, has been written by Dr. John Mason Good (1 vol. 8vo., London, 1808).

GEEFS, GUILLAUME, a Belgian sculptor, born in Antwerp, Sept. 10, 1806. After completing his studies he went to Paris, where he spent some time in the studio of M. Ramey. Soon after returning to Belgium he obtained a commission from the Belgian government to execute a monument to the memory of the victims of the revolution of 1830. The execution of this work, and of a monument to Count Frederic de Merode and a statue of Gen. Belliard, both of whom fell in that struggle, placed Geefs at the head of his profession in Belgium. He is also eminent as a poetic and imaginative sculptor, as is proved by his "Geneviève de Brabant," "Francesca di Rimini," "Fisherman's Daughter," "Infant St. John," and many similar works. Beside the monuments above alluded to, M. Geefs has executed a statue of Rubens which stands in the Place Verte at Antwerp, a colossal marble statue of King Leopold for the vestibule of the national palace, and a monumental statue of Charlemagne for the church of St. Gervais at Maestricht.

GEELONG, a town of S. Australia, and next to Melbourne the most important place in Victoria colony, is pleasantly situated in Grant co., on the S. W. shore of Port Philip, at the head of Corio or Geelong bay, 40 m. from Melbourne, in lat. 38° 8' S., long. 144° 25' E. Since the discovery in 1851 of the gold fields of Ballarat, 40 m. from Geelong, the town has rapidly risen in importance, and the population increased from 2,000 in 1846 to 28,338 according to the census taken on March 29, 1857. Its revenue increased from £2,785 in 1851 to £10,697 in 1852. The total valuation of ratable property in 1857 was £276,718. The quantity of gold dust brought to Melbourne and Geelong in 1851 was 2,829,875 ounces. In the early part of that year serious riots took place at the diggings near Geelong, in consequence of the miners resisting the payment of the license fees. This led to the abolition of the license fee and to the imposition of a tax on the export of gold. Geelong is also a chief centre for the wool trade, and carries on an extensive trade by means of the small but fine harbor of Corio, which is enclosed by picturesque green cliffs. Large vessels discharge at Port Henry, 10 m. down the bay. The surrounding country is very beautiful, the soil fertile, and the climate healthy. The town is adorned with numerous cottages and gardens, possesses an industrial school, a chamber of commerce, churches, schools, and charitable in-

stitutions. It is well supplied with water. Telegraphic communication has been established between Geelong, Melbourne, Ballarat, and since 1857 also with the other gold fields. A railway to Melbourne is in construction.

GEER, KARL DE, baron, a Swedish naturalist, born in Finspang in 1720, died in Stockholm, March 8, 1778. He studied at Utrecht and Upsal, was a pupil of Linnæus, and published *Mémoires pour servir à l'histoire des insectes* (8 vols. 4to., Stockholm, 1752-'78), containing descriptions of more than 1,500 species, accompanied with excellent illustrations. To this the *Genera et Species Insectorum* of Retzius (Leipzig, 1788) may be regarded as a supplement. De Geer also published several other zoological works. By the king of Sweden he was raised to the dignities of marshal of the court and commander of the order of Vasa. He was a member of the academy of sciences at Stockholm, to which he left his valuable collections in natural history.

GEERTS, CHARLES HENRI, a Belgian sculptor and wood-carver, born in Antwerp in 1808, died in 1855. He was professor at the academy in Louvain. Among his principal works are "Christ sinking under the Weight of the Cross," in Leyden; a Madonna in the museum of Brussels; the "Mater Dolorosa" and "St. John" in Bristol. At the great exhibition of 1851 he gained a prize medal for his chief contribution, the "Coronation of the Virgin."

GEFLE, a seaport town of Sweden, and capital of the län or province of Gefleborg, situated near the gulf of Bothnia and the mouth of the river of its name, 92 m. N. N. W. from Stockholm; pop. 9,000. Its most important public edifices are the castle, town hall, prison, gymnasium, and church. The chief manufactures are tobacco, linen, sail cloth, cards, and leather. There are two ship yards and an excellent harbor.

GEHENNA (Heb. *Ghe-Hinnom*, the vale of Hinnom), a valley adjacent to Jerusalem, on the S. and S. W., also called Tophet, and often mentioned in Scripture in connection with the idolatrous rites of Moloch, which were there celebrated. From the abhorrence with which the Jews after the captivity regarded this worship, the valley was made the common sewer of the city, and a receptacle for all its refuse, which was there consumed by fire. In the New Testament the name is transferred by an easy metaphor to hell.

GEIBEL, EMANUEL, a German poet, born in Lübeck, Oct. 18, 1816. He became associated in 1836 at Berlin with Ohamisso, Gaudy, and Kugler. In 1852 he became professor of aesthetics in the university of Munich. He has written sonnets, dramas, operas, and other poems, marked by delicacy of sentiment and a religious tone. In 1857 appeared his tragedy of Brunhilde, and in 1858 a 4th edition of his *Neue Gedichte*.

GEIGER, ABRAHAM, a German rabbi and orientalist, born in Frankfort-on-the-Main, May 24, 1810. He pursued his studies in the uni-

versities of Heidelberg and Bonn, gaining in the latter the prize for a dissertation on the Hebrew sources of the Koran. In 1832 he became a rabbi at Wiesbaden, and he is now (1859) rabbi at Breslau. His efforts to effect reforms in Judaism made him for some years the most conspicuous Jewish theologian in Germany. From 1835 to 1847 he edited the *Zeitschrift für Jüdische Theologie*, beside which he has published several critical works. His *Lehr- und Lesebuch zur Sprache der Mischna* appeared at Breslau in 1845, and his *Leon da Modena* and *Jüdische Dichtungen* in 1855.

GEIJER, ERIC GUSTAF, a Swedish historian and poet, born in Ransäter, Wermeland, Jan. 12, 1793, died in Upsal, April 24, 1847. In his *Minnen* ("Reminiscences") he has given vivid descriptions of the wild district of his birth, with its forests and torrents, the smoke and din of his father's foundry, and the simple, earnest, and upright inhabitants, who pleased him more in his school days than all his learned masters. At the age of 16 he was sent to the university of Upsal, where for a time he followed diligently the routine of study, though he expressed his conviction that the solemn forms and disputations in vogue would become the laughing-stock of future ages. He neglected to take his degree at the proper time, and consequently in 1803 was refused a tutorship in a distinguished family which his friends had sought to obtain for him. "This," he says, "was my first experience of the worth of a name and a reputation. It seemed to me that the entire world had their eyes fixed on me; my whole being was in commotion." To restore his reputation he at once determined to contend for the next prize of the Swedish academy for excellence in composition. With very meagre authorities, and with scarcely paper enough for his manuscript, he wrote a eulogy upon the Swedish administrator Steno Sturé, which obtained the first prize. Among the young men whose acquaintance he now formed was the poet Tegner. Devoting himself with ardor to study, he was graduated master of arts in 1806, and after a short visit to England was appointed in 1810 lecturer (*docent*) upon history at Upsal, and was a second time crowned by the academy for an essay on the question: "What advantages may be derived from the imagination in the moral education of man?" In 1811 he was one of the 12 young men who founded the Gothic society, the object of which was to nurture a national spirit and national manners, and to derive the materials of literature, not from classical and foreign sources, but from the ancient traditions of the North. The new school was quickly divided into two parties, the Gothic and more moderate party, of which Geijer and Tegner were the chiefs, and whose organ was the *Iduna*; and the Phosphorist party, so called from its organ the *Phosphoros*, of which Atterbom was the chief, and which unfurled the banner of a wild and unbounded romanticism. In the early numbers of the *Iduna*, which appeared from

1811 to 1824, Geijer published his finest poems, as the "Viking," the "Last Scald," and the "Last Champion," which became immediately popular. His song of the "Charcoal Boy" is still a favorite throughout Sweden. In 1814-'16 he united with Afzelius in preparing a collection of Swedish popular ballads, and after most diverse studies of philosophy, æsthetics, history, and theology, was in 1817 elevated to the professorship of history at Upsal to succeed Fant. His lectures had an almost unprecedented success, attracting not only students but the most cultivated ladies and gentlemen of Upsal. He prepared them with great care, founding his wide syntheses and striking epitomes on a thorough collation of sources. Music was a powerful assistant to him in every kind of labor, and he was wont to play on the piano as a preparation alike for writing a lecture or a song. Liberal both in politics and religion, he was twice offered a bishopric, which he declined, and twice represented the university of Upsal in the diet. His heavy censure of the nobility, and of the part which they played in the early history of Sweden, gave rise to a lively controversy with Fryxell. Many of his minor pieces, in which he treated political, literary, and religious questions, are remarkable, but his chief distinction is as the historian of Sweden. He was appointed with Fant and Schröder to edit the collection of *Scriptores Rerum Suecicarum Medii Ævi* (2 vols., Stockholm, 1818-'25). His *Seva Rikes Hæfder* ("Annals of Sweden," Upsal, 1825; translated into German, 1826) is a collection of dissertations on the early history and antiquities of the kingdom. His principal work is the *Svenska Folkets Historia* ("History of the Swedish People," 8 vols., Örebro, 1832-'6; translated into German by Leffler, Hamburg, 1832-'6; into French by Lundblad, Paris, 1840; and into English by Turner, London, 1845), which extends only to the death of Queen Christina, but has been continued by Carlson. The work of Fryxell is also regarded as a supplement to it. At once a history of ideas, of manners, and of institutions, it is remarkable both for eloquence and learning, for its patriotic tone, synthetic views, and suggestive power. Among his minor publications are a "Sketch of the State of Sweden from Charles XII. to Gustavus III." (Upsal, 1839), and a "Life of Charles XIV. John," or Bernadotte (Upsal, 1844). A complete edition of his works was published at Stockholm (13 vols., 1849-'55).

GEINE (Gr. $\gamma\eta$, the earth), a name formerly given by Berzelius to the insoluble residue left by treating the substance he called humus with alkaline solutions. Dr. Samuel L. Dana considered it the same as humus, the decomposed organic matter of the soil, and regarded it as a definite substance which it is the object of the cultivator to produce in the compost heap. His views are fully presented in the "Final Report on the Geology of Massachusetts," by Prof. Hitchcock (vol. i. p. 87 *et seq.*, and p. 121 *et*

seq.), and in the table of about 150 analyses of soils, commencing on p. 41, he presents the proportions of geine, soluble and insoluble, these contained.

GELA, an ancient city of southern Sicily, on a river of the same name, now Fiume di Terra Nuova, founded (about 690 B. C.) by a colony of Rhodians from Lindus and Oretans. It soon became flourishing, and was the parent of Agrigentum, now Girgenti, which afterward surpassed the might of the mother city. The popular constitution of Gela was overthrown by Cleander, who was the first of its tyrants. His brother Hippocrates succeeded him, and extended its influence and power over the greatest part of Sicily. His successor Gelon's transfer of the seat of his power and of a part of the inhabitants of Gela to Syracuse (485), his brother Hiero being made governor of the former, caused its decay; and its desolation was completed by Phintias, tyrant of Agrigentum, who removed its inhabitants to a new town, to which he gave his name (280). In the time of Augustus it was already in ruins, which are still visible in the vicinity of Terra Nuova.

GELATINE, a jelly extracted from animal tissues, by boiling them in water. Isinglass and glue are varieties, an account of which will be included in this article. In its purer forms, as the commercial gelatine and isinglass prepared for food, it is in colorless, transparent, thin sheets or shreds of semi-horny texture, without taste or smell, varying in toughness according to the particular tissue from which it is prepared. It dissolves in hot water, and becomes a jelly of stiffness proportionate to the quantity dissolved. The colder the temperature the smaller is the quantity of water required for the jelly to appear. Exposure of the solution to greater heat than 212° F., as also frequent repetition of the process of liquefying and gelatinizing, lessens the consistency of the jelly in proportion to the heat applied and the length of time the solution is kept warm. The property of gelatinizing is also partially lost if the solution begins to sour. The common method of keeping and employing glue in the glue-pot made to prevent an accession of temperature above 212° F., is based upon this property. The tendency to putrefaction in glue may be prevented by adding acetic acid, which does not affect its adhesive quality. The presence of gelatine in a solution is indicated by the dense white precipitate caused by the addition of a solution of tannin, such as that contained in the solution of galls. Reciprocally gelatine is a test of the presence of tannic acid. Alcohol does not dissolve gelatine; but added to its aqueous solution, which should be warm and somewhat concentrated, the gelatine coagulates in a white, elastic mass, which strongly adheres to the vessel. Gelatine is also insoluble in ether and the oils. The addition of alcohol to gelatine in a state of jelly causes it to part with a portion of its water and contract greatly. A print has been taken upon a thin film of the jellied substance,

which being then reduced in size by this means was made to give upon stone a new impression of smaller but proportional dimensions. An enlarged print may be obtained by steeping the gelatine in cold water after it has received an impression. Gelatine is believed to consist, in 100 parts, of carbon 13 equivalents = 50 per cent.; hydrogen 10 = 6.41; oxygen 5 = 25.64; nitrogen 2 = 17.95. Various methods are in use for preparing the gelatine sold for making jellies, blanc-mange, &c. For the best article the skins of calves' heads and other thick pieces which are unfit for the manufacture of leather are first freed from hair and thoroughly cleaned of flesh and fat, and well washed. They are then reduced by cutting machinery to small pieces or to a pulp, cold water being allowed to run through the pieces during this operation in order to remove all impurities. The pieces of skin or pulp are differently treated by different manufacturers in order to obtain the solution most readily, some employing the mechanical force of rollers in conjunction with the application of a temperature varying from 150° to 212°. When the solution is obtained it is clarified with some albuminous matter, as the white of eggs or ox blood, and after settling is drawn off upon shallow coolers, as plates of glass or slates. When partially dry, so that it can be cut into convenient shapes for handling, it is removed upon nets or placed in a vacuum drying apparatus to complete the process of desiccation. In the course of the preparation the article is flavored with essences. The French gelatine is said to be whiter than the English in consequence of their calves being killed at an earlier age. The hides of the ox are sometimes used as well as those of calves. Bones and ivory also are made to yield gelatine by subjecting them, when crushed, to water boiling at high temperatures in a digester, or to the action of steam gradually raised to the pressure of 33 pounds to the square inch, and thus kept for 3½ hours. By this means their soluble portions are taken up, and the earthy matters, about 60 per cent. of the whole weight, are left behind, together with a soapy substance produced from the fat and lime of the bones. This residue is used for the manufacture of bone black, or the preparation of phosphorus, and is beside an excellent material for composts. The manufacture of gelatine has been largely carried on in France by first removing the earthy salts from bones by digesting them for many days in dilute hydrochloric acid, and afterward in boiling water. For this use the more porous bones of the heads of animals were preferred, and the clippings of button manufacturers. The acid liquors contain the phosphate of lime of the bones in the form of a soluble biphosphate, from which the phosphorus is obtained by the manufacturers of this article, and they also contain ammoniacal products, which render them valuable for composts. For a long time gelatine was largely employed in the hospitals and pauper establishments of Paris, as a cheap and,

as it was believed, very nutritive material for soups. Its value for this purpose was at last questioned, and the commission appointed to investigate its qualities reported unfavorably. (See ALIMENT.) Great skill, however, had been attained in the methods of manufacture, and this is still available in the extraction of gelatine from bones for other purposes. Even the dry bones of the mastodon had been made by the acid process to yield the gelatine for a soup. In the practice of 11 years at the hospital of St. Louis at Rheims the production from 100 parts of dried bones was as follows: gelatine 28.904, fat 7.216, bone residue 64.580. As the bones contained an average of only 30 per cent. of gelatine and 10 of fat, the process was much more perfect than that of the glue manufacturers, who obtained of gelatine only from 10 to 15 per cent. of the weight of the bones they employed. This is ascribed to the moderate pressure of steam and reduced temperature, not exceeding 223° F., employed in the digesting process.—But though gelatine is insufficient of itself to support life, its almost universal use in some form of food attests its importance as an article of diet. It also finds numerous other uses, as for the clarifying of liquors, the manufacture of cements, as a chemical test for tannin, and in pharmacy for coating pills and forming pouches or capsules in which disagreeable medicines may be concealed and swallowed without disgust. It is also applied in the dressing of silks and other stuffs. It is made by the French into thin transparent sheets called *papier glacé*, which are used for copying drawings; and they also prepare from it artificial flowers richly colored to imitate the natural specimens, or presenting the appearance, in their glittering and semi-transparent substance, of flowers wet with dew or drenched with rain. Another application of gelatine is for taking casts or forming moulds of objects presenting complicated forms, for retaining which plaster is not sufficiently adhesive. A series of casts in imitation of ivory were produced in this substance in 1844 by M. Franchi, for which the prize of the London society of arts was awarded in 1846. He afterward obtained gelatine casts from moulds of the same substance, the lines being perfectly retained in their original sharpness. He also took casts in gelatine from flat models, which he applied to cylindrical bodies, thus saving much expense in the carving or construction of intricate models.—*Isinglass* is the best known form of edible gelatine. It is the dried air bag, sound, or swimming bladder of fishes, known to the ancients by the name of *ichthyocolla* or fish glue, and often alluded to by Dioscorides and Pliny. In different parts of the world this product is obtained from different fishes, and the isinglass of commerce is consequently of various qualities. The best is found among the varieties imported from Russia, particularly that which is brought to St. Petersburg from Astrakhan, and said to be obtained from the sturgeon called the beluga (*aci-*

penser huso) of the Caspian sea and the rivers which flow into it, a species which attains a length of 25 feet. According to some authorities the sound is cut open, washed, and then exposed to the air, the inner silvery membrane outward. This membrane is then stripped off, placed in damp cloths and kneaded in the hands. Taken out and dried, it forms the leaf isinglass; folded like sheets of paper, it is the book isinglass; wound in the form of a horse shoe or lyre around 8 pegs, it forms the varieties known as long or short staple. According to Martin, the inner membrane is removed by beating and rubbing, and the thicker membrane is preserved. The isinglass called Samovey is brought from Taganrog. The leaf, book, and short staple of this locality are all of inferior quality. The varieties from the Ural and Siberia are better. The Brazilian isinglass, imported from Para and Maranhão, is obtained in various forms distinguished as pipe, lump, and honeycomb. It appears to be the product of different kinds of fish, and to be prepared with little care. It is largely used in brewing establishments for fining the liquors; and though it is too impure for domestic uses, there is no doubt it is largely employed to adulterate the better articles. Its presence may be detected by the isinglass failing to dissolve readily and completely in hot water, and by its forming with this an opalescent and milky jelly in which may be observed the insoluble shreds common to the Brazilian article. Its smell also is often disagreeable, while that of the pure Russian isinglass is as inoffensive as the odor of sea weed, which it somewhat resembles. The isinglass of New York and New England is obtained from the sounds of the codfish (*morrhua vulgaris*) and of the common hake (*phycis Americanus*). They are macerated in water, and afterward rolled out in long strips of a few inches in width. The quality of the isinglass is poor, its solution not readily obtained, and its color dark. It is used for the same purposes as the Brazilian. Other varieties are produced in other maritime countries.—All isinglass has to undergo a process of refining before it is fit for making jellies, blanco-mange, &c. The best beluga leaf is imported in sheets of circular form, the most perfect of which are sometimes 2 feet in circumference, and weigh from 8 to 16 oz., in some instances reaching even 4 lbs. These are carefully picked over, and all the discolored parts are cut away and put aside for uses of less importance. The assorted leaf is then rolled out by machinery and passed through successive pairs of iron rollers, until it is converted into thin ribbons of uniform width. These are afterward by other machinery slit into fine shreds. Inferior sheet gelatine is sometimes introduced between two sheets of isinglass before rolling and thus incorporated with it. Isinglass, being a nearly pure gelatine, should have little or no color; and being commonly prepared without exposure to high degrees of heat, it should be tougher and more

elastic than the other forms of this substance. It should therefore make a most adhesive cement, and such is found to be the case. It is for this purpose swollen with cold water, and then placed in diluted alcohol. The vessel containing it is then put into cold water, which is to be heated to boiling. The jelly forms the cement, which may be kept from mouldiness and other change by the addition of a few drops of any essential oil. It is known as the "diamond cement," and is also the adhesive substance of court plaster. Gum ammoniac is sometimes introduced, as by the Turks, who use the cement for fastening precious stones, mending broken porcelain, glass, &c. Isinglass has also been used for the window lights of vessels, being covered with a transparent varnish which is not affected by moist air. Beside the methods already stated of detecting fraudulent mixtures with isinglass, the microscope may be used to render the different textures apparent. The ash of isinglass seldom exceeds $\frac{1}{2}$ per cent. and is of a red color; that of gelatine is white, and in quantity not less than 8 per cent.—GLUE, the most impure form of gelatine, is obtained from a great variety of refuse animal matters, as fragments of hides, scraps of leather which has not been tanned, skins from the furriers, hoofs, horns, tendons, intestines; in fact, almost any part of animals can be advantageously used in this manufacture. Bones are employed by the French as in the manufacture of edible gelatine; but when intended for glue, the process of dissolving out the earthy matters with hydrochloric acid is preferred to the steaming, the latter requiring a degree of heat which diminishes the adhesive quality of the glue. The animal matters are first subjected to a process of maceration in lime water for several weeks or months, by which their putrefaction is prevented, and they are rendered soft and more readily acted upon in the subsequent digesting operation. The lime water is frequently renewed in the vats. When taken out they are rinsed with water, and laid upon a sloping surface to drain and dry, where they are turned several times a day. By this exposure the quicklime is carbonated, and what remains attached is thus rendered harmless to the glue, from which it is afterward separated, together with the fatty matters, in the clarifying. The digestion is conducted in large boilers containing water, within which the animal matters are introduced in an open-mouthed bag or net made of rope, the contact of which with the inner sides of the vessel is prevented by a light frame of iron which serves as a lining to the boiler. The contents are occasionally stirred and pressed down with poles, and added to as their bulk diminishes by boiling. When samples of the solution are found to gelatinize on cooling, the bag with its contents is drawn up out of the boiler by a large permanent windlass, which is fixed for the purpose at a considerable height above the boiler, and which is rolled by the machinery. By winding the bag as closely as possible to the shaft of the

windlass its contents are compressed, so that they rapidly drain and the liquid portions are made to fall back into the boiler. The more solid contents by a second boiling furnish more gelatine, which may be made into size, or the solution may be used to boil a fresh portion of animal matters. The final refuse is used for manure. The liquid in the boiler is evaporated to a proper consistency, and is then drawn off into a vessel called a settling-back, in which it can be kept liquefied by heat. In this the solid impurities settle, and the others are separated by clarifying the liquid with alum or other fining substances. This process completed, the glue is run out into coolers, which are wooden boxes about 6 feet long, a foot wide, and 6 inches deep. In these, if the room is cool, it solidifies sufficiently in the course of 12 to 18 hours to be cut with spades into cubical blocks. Each one of these is placed in a wooden box, made with open slits in the back to admit a wire, by which the blocks are cut into slices. These are placed upon nets stretched in wooden frames, and are then taken to the drying ground, where, protected by a temporary roof, the frames are piled up, so that the air can circulate through them. The whole require turning several times a day to expose all portions equally to the air. In this part of the manufacture the glue is particularly liable to injury from the weather. Too great dampness will make it mouldy; in too dry weather it will warp out of shape; in too hot weather it will soften and run upon the nets, or even flow through them; frost will cause it to crack in every direction by the freezing of the water within it; and a thunderstorm will prevent its hardening. The days of moderate weather of spring and autumn are the best for the drying operation. But this is not completed in the open air; the glue is removed to lofts and left for weeks or months; and as the slices become mouldy and soiled they are scrubbed with a brush and hot water and set up to drain. At last they are exposed to the high temperature of artificially heated rooms, by which the glue is properly hardened. The strongest glue is in thin sheets of a dark color, free from cloudy spots, and partially transparent. It swells in cold water without dissolving, and returns to its original size on drying. When used, it should be broken into small pieces and left for 24 hours in cold water; it may then be slowly melted by heat with frequent stirring. The jelly which forms on cooling may again be liquefied by heat without adding more water; but on frequent reheating it dries less readily, and partially loses its adhesive quality for which it is chiefly of value. Allusion has already been made to the provision furnished in the glue pot against its being exposed to a higher heat than that of boiling water. It should also be protected against a freezing temperature.—A glue that is not liable to be affected by dampness, and is a very tenacious cement, is made by immersing gelatine or glue, after it has been swollen in

cold water, in linseed oil and heating it; also by dissolving isinglass in skim milk instead of water. The quality of glue may be judged of by the quantity of water which the dry glue will absorb in 24 hours. The best glue kept immersed in water of the temperature of 80° F. has absorbed 12 times its weight. Other qualities, it is said, take up a proportionally less quantity. Beside its use for cementing wood and hard substances, glue is sometimes employed by the hatter in preparing the felt bodies of hats, and by the printer as an ingredient in the composition of inking rollers, to give them flexibility. —Several varieties of glue are employed in the arts, some of which may properly be noticed here, although they are not all preparations of gelatine. By treating glue with a small proportion of nitric acid it loses its property of gelatinizing when cold, though not that of causing substances to adhere together. With acetic acid a similar effect is produced. What is called liquid glue is made by slowly adding nitric acid to the ordinary preparation of glue in the proportion of 10 oz. of strong acid to 2 lbs. of dry glue dissolved in a quart of water. The product is a strong glue, which remains in a liquid state, and may be thus kept for years always ready for use. Marine glue is a preparation of caoutchouc dissolved in naphtha or oil of turpentine, with the addition of shell lac after the solution has by standing several days acquired the consistency of cream; 2 or 3 parts by weight of shell lac are used for one of the solution. The composition is then heated and run into plates, and when used it is heated to the temperature of about 250° F. It possesses extraordinary adhesive properties, and being quite insoluble in water, it has been recommended as a material for fastening together the timbers of ships; so securely are these held by its application that it is stated they will sooner break across the fibres than separate at the joint.

GELDERLAND, or GUELDERLAND, a province of Holland, bounded N. W. by the Zuyder Zee, S. E. by the Prussian dominions, and on the other sides by the provinces of Overijssel, Utrecht, and North Brabant; area, 1,972 sq. m.; pop. in 1857, 396,421. Its surface is more hilly than that of most of the Netherlands; its climate is mild, but its soil, except in the river valleys, is poor. The principal streams are the Meuse (separating it from North Brabant), Waal, Rhine, and Yssel, on the banks of which fruit, grain, hops, potatoes, and tobacco are cultivated with considerable success, while the more sterile districts have recently been planted with timber, or are used for cattle-raising. Brewing, distilling, and the manufacture of paper, linen, tiles, and leather, are important branches of industry, and there is also an extensive transit trade. There are iron mines in the canton of Zutphen. The herring fishery is actively prosecuted on the Zuyder Zee. For administrative purposes the province is divided into the districts of Arnhem, Nimeguen, Thiel, and Zutphen. Arnhem, the capital, Nimeguen, Zutphen, and Har-

derwyk are the chief towns. Gelderland was made a county in 1070 by the emperor Henry IV., and a duchy in 1389 by Louis of Bavaria. It was governed by dukes of its own, who resided at its present capital, until 1528, when it passed into the hands of Charles V. It joined the league of Utrecht in 1576; in 1794 it was taken by the French, who held it 20 years, and in 1814 it became a part of the Netherlands. A portion of upper Gelderland (area about 400 sq. m.), including its capital Geldern (pop. 3,500), was added to Prussia by the peace of Utrecht (1713), and now forms part of the circle of Cleves in the Prussian district of Düsseldorf.

GELL, SIR WILLIAM, an English scholar and antiquary, born in Hopton, Derbyshire, in 1777, died in Naples, Feb. 4, 1836. He was graduated at Cambridge in 1798, was for a time a fellow of Emmanuel college, and was afterward sent on a secret mission to the Ionian islands. In 1814 he accompanied the princess of Wales abroad as one of her chamberlains, and was one of the witnesses at her trial, after she had become queen. He subsequently returned to Italy, where he sojourned till his death. Gell was a voluminous writer on classical antiquities. His principal works are: the "Topography of Troy and its Vicinity" (1804); "Itinerary of Greece, with a Commentary on Pausanias and Strabo" (1810); and "Pompeiana, or Observations upon the Topography, Edifices, and Ornaments of Pompeii" (1817-'19). Of the last, which has attained a greater popularity than any other of his works, a continuation in 2 vols. 8vo. was published in 1836.

GELLERT, CHRISTIAN FÜRCHTEGOTT, a German poet and moralist, born in Hainichen, Saxony, July 4, 1715, died in Leipsic, Dec. 18, 1769. He was one of the early promoters of the great literary movement which produced Schiller and Goethe. His lectures upon poetry and morals delivered at Leipsic, at first as private instructor and afterward as professor of philosophy in the university, attracted crowded audiences. Goethe in his youth was one of his disciples, but judged his ethical system to be of an effeminate tendency. He published fables, stories, letters, sacred hymns and odes, and a romance entitled the "Swedish Countess," all admirable for their *naïveté*, and which were favorably received by the public, and have been often republished. Feeble health and attacks of hypochondria paralyzed his intellectual activity in the last years of his life.

GELLIUS, AULUS, a Roman grammarian, who flourished about the middle of the 2d century A. D., supposed to have been born in Rome. He studied rhetoric there, and philosophy at Athens. He was still a youth when he commenced, during the long winter evenings spent at a country house near Athens, a compilation of extracts from Greek and Roman authors, concerning languages, antiquity, philosophy, history, and literature, interspersed with original remarks. He continued it at Rome, where he held a judicial office. His work,

named from its origin *Noctes Atticae* ("Attic Nights"), and divided into 70 books (of which the 8th is lost), though without any attempt at order or arrangement, contains a mass of materials, valuable mostly as remnants of lost ancient authors. It was published at Rome (1469), at Leyden (1706), by Gronovius, and at Göttingen (1824), by Lion.

GELON, a ruler of Syracuse, born in Gela in Sicily, died about 478 B. C. He served gallantly as commander of the cavalry, under Hippocrates, tyrant of Gela; on whose death, the people revolting against his sons, Gelon supported the latter, but finally set them aside and assumed the chief power himself (491 B. C.). Called to the assistance of the Gamori, the landed aristocracy of Syracuse, then expelled by the revolted slaves and the popular party, he contrived to become master of that city, appointed his brother Hiero governor of Gela, and by degrees extended his influence and power over all Sicily. He seems to have won the affections of the Syracusans by mildness, by the protection of arts and sciences, and by the aggrandizement of the city, for which purpose he even destroyed Camarina and other towns, and transplanted their inhabitants thither, as well as half the population of Gela. When Xerxes was threatening the invasion of Greece, the Lacedæmonians and Athenians invoked the assistance of Gelon. He promised a fleet of 200 vessels, 20,000 heavy armed and 6,000 light armed infantry, and 2,000 cavalry, upon condition of being elected chief and leader of the allied Grecian armies. To this the Lacedæmonian ambassador, according to Herodotus (vii. 159), replied: "If thou intendest assisting Hellas, go and be commanded by the Lacedæmonians; if thou disdainest to be commanded, stay away." He then sent an ambassador to Delphi, with rich gifts, and orders to greet and acknowledge Xerxes if victorious. Herodotus, however, also mentions a different version of the affair, which vindicates the character of Gelon and the policy of the Syracusans in not assisting Greece. They were fully occupied at home, for the Carthaginians at this juncture invaded Sicily with a great army. Gelon completely defeated them at Himera, on the same day, according to Herodotus, on which the Greeks won the victory of Salamis (Oct. 20, 480 B. C.), but according to Diodorus, on the day of the battle of Thermopylæ. He now proposed to resign his power, and restore popular liberty, but the offer was rejected in the assembly, and his exhibition of magnanimity was rewarded with the title of king, which he accepted and bore till his death. The Syracusans erected, against his will, a splendid tomb to his memory, and honored him as a hero. When Timoleon, 180 years afterward, sought to destroy all vestiges of the tyrants, the statue of Gelon was excepted. His brother Hiero was his successor.

GEM (Lat. *gemma*, a bud), the name of precious stones, prized for their brilliant lustre and splendid colors or perfect limpidity. They possess

also a hardness which renders them susceptible of the highest polish, and capable of retaining unimpaired the forms into which they are cut and the lines or figures that may be engraved upon them. These properties, in connection with their rarity, have given to them the highest value of all substances. The choicest among them have been prized above all other earthly possessions, consecrated by idolatrous nations to their gods, and by the civilized purchased at prices which the wealthiest governments alone could pay, to be held among their most valued treasures. These are commonly called crown jewels, and comprise diamonds, rubies, and emeralds, the largest of which may be hidden in the hand. The finest specimens of these are noticed under their respective titles; and reference may also be made to AGATE, CHRYSOBERYL, CHRYSOLITE, GARNET, SAPPHIRE, TOPAZ, TOURMALINE, &c., for accounts of other species of beautiful gems. These stones, which may be regarded as the richest flowers of the mineral kingdom, are not, like those of the vegetable world, usually presented by nature in their full beauty; but they are found in the form of worn pebbles among the sands derived from the disintegration of the rocks in which they were originally contained. Some, however, are obtained crystallized in the matrix of quartz, calcareous spar, or other gangue of veins in which they were produced, or in geodes, of the dark cavities of which they made with other crystals a lining or incrustation. The crystals may have the perfections of the stone fully developed, but art is not satisfied with the form, and this is almost always sacrificed to fit the stone to the conventional shapes judged best suited to display its highest lustre. The rough pebble, in whose dull exterior only a practised eye would recognize the gem, of course requires the work of the lapidary to develop its beauties. The processes to which the stones are subjected are described in the articles DIAMOND, and LAPIDARY; the method of carving them to bring out from their differently colored layers figures in relief is described under CAMEO; and GEM ENGRAVING will be treated in this article.—To distinguish gems from each other and from their artificial counterfeits, a practised eye has been generally sufficient; but the modern imitations, the manufacture of which is described at the close of this article, are so perfect, that the tests of comparative hardness and of specific gravity may often be required. The chemical tests which are usually employed to distinguish minerals cannot be applied to these stones on account of the injury they would occasion. The finest collection of gems in the world is that of the emperor of Russia. Siberia has proved a rich field for their production, and all precious stones found there belong to the crown. They are taken to Ekaterinburg, and being cut and polished in the government works, the choicest are selected for the imperial treasury. Clarke in his account of his travels in Russia makes frequent reference to the abundance

of fine gems met with in the cabinets and jewellers' shops, and states that in Moscow they were so much more highly prized than in western Europe, that the most costly gems were sometimes purchased in London to be deposited in Russian collections. Mr. Bayard Taylor made the following observations while at Moscow in 1858: "The shops of the jewellers are interesting, from the variety of precious stones, chiefly from the mountains of Siberia, which are to be found in them. The jewels most fashionable in Moscow at present are diamonds, emeralds, pearls, and turquoises. Opals also bring a large price, but stones of a secondary order, such as topaz, garnet, amethyst, onyx, and aquamarine, are plentiful and cheap. Siberia produces superb emeralds, and the finest amethysts, aquamarines, and topazes I ever saw. The Siberian diamond, which is found in abundance in the Ural mountains, appears to be neither more nor less than a white topaz. A necklace of 75 of these stones, the size of a cherry, costs a little less than \$20. I noticed a few fine sapphires, but suspect that they found their way hither from India, through Persia. One jeweller showed me a jacinth, a rather rare stone, with a splendid scarlet fire, for which he demanded 50 rubles. There were also some glorious opals, darting their lambent rays of pink, green, blue, and pearl-white, but their value was equal to their beauty. Malachite and lapis-lazuli, so common in Russian palaces and churches, are dear, and good specimens are not easy to be had." Different Asiatic countries, particularly Hindostan, Pegu, and Ceylon, have been famous from the remotest periods for their rich gems; and in modern times Brazil and Peru have almost rivalled them in these rare productions.—

GEM ENGRAVING, known also as the glyptic art (Gr. γλυπτός, to engrave), was skillfully practised in very remote times. In Exodus xxviii. 17-20, the following stones are designated as those upon which were engraved the names of the 12 children of Israel: sardius, topaz, carbuncle, emerald, sapphire, diamond, ligure, agate, amethyst, beryl, onyx, and jasper. At this early period, as we learn from verse 11 of the same chapter, engraving of signets, and upon the hardest stones, was practised. The Israelites, it is believed, acquired the art from the Egyptians, who are known to have made use of the lapidary's wheel and emery powder, and are supposed to have been acquainted with the diamond and the method of engraving other hard stones by means of it. (Wilkinson's "Ancient Egyptians," vol. ii. p. 67.) Specimens of their work are still preserved in European collections, and also of that of the Etruscan artists of a somewhat later period. The Assyrians and Babylonians were very skilful in engraving on gems, great numbers of which have been found in the ruins of their cities. Many of their seals are most delicately and minutely ornamented with various sacred devices and with the forms of animals. The Greeks adopted the art, and practised it with the greatest zeal and suc-

cess. Their works of the time of Alexander the Great are still the most perfect specimens. The most distinguished among their earlier artists was Pyrgoteles, who alone was permitted to engrave the head of Alexander, as Apelles only was allowed to paint his portrait, and Lysippus to cast his image in bronze. In the time of the Roman emperors, Dioscorides from Æolia in Asia Minor attained the highest eminence. His head of Io is regarded by some as the finest engraved gem in existence, and others almost equally beautiful are two busts of Augustus, a head of Demosthenes on an amethyst, and various mythological representations. Several of the most skilful artists of Greece established themselves at Rome under the emperors. With the empire the art declined, and though the mechanical execution was not lost, no productions of genius appeared till the 15th century. At this time it became fashionable to make collections of antique gems, and among others Lorenzo de' Medici was especially interested in this object and in encouraging artists to imitate the finest productions, in which they attained great success. The same taste soon spread to France, Germany, and England; and in all civilized countries the art has since been held in high estimation. As applied to the hardest gems, as the diamond, ruby, sapphire, and topaz, it is no doubt carried to a higher degree of perfection than was attained in ancient times, for among the antique engraved gems preserved there are few if any of this class. Engraved gems are for the most part readily referred by connoisseurs to their true period, country, and sometimes to the artist himself. Each had his own cipher, which is commonly found upon the gem, though this is in modern times imitated, together with the peculiar style of the ancient artists and their complete work, in great perfection. Specimens of Egyptian art are recognized by the representations of the peculiar favorite animals and divinities of this people, accompanied with their hieroglyphics. Their gems were engraved almost exclusively in intaglio, and they were of the form designated as *scarabæi*, from the upper surface of the stone, always of the oval form, being cut to represent the beetle. The Etruscans also adopted this form, but their devices more resemble those of the earliest Greek workmanship. Their specimens are distinguished by low relief, a granular border surrounding the engraving, stiffness in the figures, peculiar style of letters and writing, wings given to the deities which the Greeks represent without wings, and names generally attached to the figures. The Greeks also practised chiefly in intaglio, and some of their finest works are in chalcidony and carnelian. The highly famed Dionysiac bull of Hyllus, an artist supposed to have lived before the age of Augustus, is upon chalcidony; and a celebrated specimen in carnelian is the beautiful seal of an unknown artist which once belonged to Michel Angelo, and was afterward preserved in the imperial library at Paris. The engraving represents a vintage, but the design

has been referred in various learned dissertations to a number of different objects, some of mythological character. Many impressions and copies have been taken of this famous specimen. The engraved gems of the first 15 centuries A. D., excepting the imitations of antique works, generally have designs from scriptural subjects—images of Christ and of the Virgin Mary, representations of the Good Shepherd, and often a fish, symbolical of the Saviour, from the letters in its Greek name, *ἰχθῦς*, being the initial letters in the appellation *Ἰησοῦς Χριστός Θεοῦ Υἱός Σωτήρ*. Some terms employed to designate certain styles of antique gems may be properly noticed here before speaking of the art in modern times. Stones convex on one side are said to be *en cabochon*; *chimæra* are those with representations of imaginary beings made up of portions taken from different animals; *grylli* are those with hideous heads, said to be so called from an Athenian named Gryllus, who was extraordinarily ugly; *conjugata*, or joined, are those with heads represented together upon the same profile—called opposite when they face each other. Engraving was practised both in intaglio and in rilievo, and the two styles were sometimes combined in the same specimen. Stones having differently colored layers, like the onyx, were especially adapted for the rilievo style, for an account of which see CAMBIO.—In modern times the finest gem engravers are found among the Italian artists of the 18th century and chiefly those of Florence. Some of their works are hardly inferior to those of the most famous Grecian artists. Flaviano Sirletti of Florence, who died in 1787, was especially distinguished for his copies of ancient gems and exact imitations of the ancient letters. The Costangis and many others also attained great repute; and in the present century are some whose productions, as those particularly of Signor Rega of Naples, rank with the famous antique gems. Among the Germans, Daniel Engelhard of Nuremberg, a friend of Albert Dürer, was celebrated for his skill in engraving crests and arms. He died in 1552. The works of the Pichlers, father and son, who came from Tyrol, are of the highest merit, especially those of the father. The son was much in Italy, and is often spoken of as an Italian. The celebrated Poniowski collection of antique gems has recently been credited to the elder Pichler. Natter of Swabia, who died in 1768, was not only a workman of the most delicate skill and refined taste, but a student and author also, and published in 1754 the only treatise specially devoted to his art: *Traité de la méthode de graver en pierres fines*. From this work it appears that the ancients employed the same sort of tools and the same methods as those in use at the present day. The modern practice is described by Holtzapffel in vol. iii. of his "Mechanical Manipulation." He speaks in high terms of the works of English artists, specimens of which, collected in Italy, have been credited to the artists of that country; and he names as especially distinguish-

ed, Wray, Burch, Marchant, and Charles and Henry Weigall; to which names may be added Pistrucchi and the Wyons. The apparatus employed in engraving consists of a foot lathe attached to a small table, upon which is fixed a little pillar for holding the horizontal pulley, which is the receptacle for the cutting tool. This part of the apparatus is called the mill. The tools are soft iron wire spindles carefully annealed and nicely fitted to the hollow axis of the pulley. Only one is used at a time. When set in its place it projects through the bearings of the pulley, one end extending horizontally on the right hand side of the operator, who sits at his work in front of the table. This extremity of each tool is fashioned for its special work. Most of them terminate in a small disk, the edge of which, as it rotates rapidly, cuts lines in the stone held up against it, the tool being fed with diamond dust and oil. The larger sized disks are only about $\frac{1}{4}$ inch in diameter, and from this they are made of decreasing sizes down to $\frac{1}{16}$ of an inch, when the disk can scarcely be distinguished by the eye from the stem. They are also variously shaped for special kinds of cutting. The stone intended to be engraved is usually shaped by the lapidary, and is sometimes set by the jeweller before it is engraved. If not set, the engraver secures it to a wooden handle by the cement known as the lapidary's; or if set, he secures it in a notch in a piece of cork. The polish is removed by roughening the face with a suitable cutting powder, as the tools work better upon a rough surface, and the outline of the design, which is next marked with a brass point, is the more conspicuous. The area thus enclosed is then sunk by the tools to a suitable depth; and within this the details of the design are successively introduced and excavated. For the parallel lines called color lines, a thicker disk with two cutting edges is employed, its form being that of a little pulley; the two edges are just as far apart as the lines they are intended to cut, and as one pair is cut the stone is moved so as to bring the outer edge of the disk into the groove marked by the other edge, and thus the work goes on step by step over the surface to be thus "colored." The plan must be perfectly understood by the artist at the commencement of his work, and as it goes on he watches the effect produced with the aid of a magnifying glass conveniently attached to a stand over the tool, and occasionally takes a proof of his work in wax. After the stone is engraved the polish is restored to the flat surface by a pewter polishing disk or lap fed with rotten stone and water. The engraved portions are polished with great care, first by using in the mill copper tools charged with diamond powder; this buries itself more deeply in the copper than in the iron tools, and a smoother surface is thus obtained. Box wood tools charged with still finer diamond powder are next used, and after these copper tools charged with rotten stone and water. The harder gems, excepting

the diamond, which is engraved with the greatest difficulty, are better adapted for this process than those of softer quality. The latter are liable to hold the diamond powder and cause it to wear out the tools; they do not when finished present such smooth and highly polished surfaces as the harder stones. The amethyst is considered as soft a stone as can be cut very smoothly. Carnelian and bloodstone are of close texture, and admit of excellent work; the ruby cuts slowly, but small pieces are apt to flake off. The sapphire is firm and close; it cuts slowly, but presents beautifully smooth surfaces.—**ARTIFICIAL GEMS.** The great value attached to precious stones led at an early period to successful attempts to imitate them. The Egyptians possessed the art of coloring glass, and among their mixtures they produced excellent imitations of the most beautiful gems, so that, as Pliny states (xxxvii. 12), it was difficult to distinguish the false from the real. Their artificial emeralds, sapphires, and hyacinths are spoken of by various ancient authors. Some of the first named were of such gigantic size that they were used in the construction of statues, as of that of Serapis in the Egyptian labyrinth, 18½ feet in height. Another presented by the king of Babylon to an Egyptian Pharaoh was 6 feet long and 4½ broad; and an obelisk in the temple of Jupiter 60 feet high and 6 feet broad was composed of 4 artificial emeralds. (Wilkinson's "Ancient Egyptians," vol. ii. p. 68.) These were very extraordinary productions if made only of pieces of colored glass. Seneca also makes mention of one in his time who manufactured artificial emeralds. Beckmann states that in some ancient collections at Rome are pieces of colored glass, which were once used as jewels. In the Museum Victorium are seen a chrysolite and emerald of faultless execution. In the 17th century the discovery of the preparation of gold and binoxide of tin, called purple of Cassius, afforded the means of giving a ruby red color to glass, and artificial rubies were then first made, especially by one John Kunkel, afterward Löwenstern, inspector in 1679 of the glass houses in Potsdam. In modern times the art has been wonderfully perfected by the French, chiefly through the genius of M. Donault Wieland. A glass called strass, of great lustre and perfectly transparent, of which the ingredients are given in the article GLASS, is prepared as the basis of the composition. It resembles the diamond in high refractive power as in its other qualities, except hardness. That it may be free from color its ingredients must be absolutely pure; and care must be exercised in selecting crucibles least likely to impart color to the fused mixture. The pure glass without addition of other matters may be cut into the forms adopted for the diamond and pass for this gem. Emerald is imitated by adding 8 parts of pure oxide of copper and 0.2 part of oxide of chromium to 1,000 parts of strass; sapphire, by adding 15 of pure oxide of cobalt to 1,000 of very white strass, the fu-

sion in a heated Hessian crucible to continue 80 hours. Topaz, to 1,000 of the same quality of strass, requires 40 of perfectly transparent yellowish orange-red glass of antimony and 1 of purple of Cassius; or, instead of these, 10 parts of oxide of iron. With the first the tint varies with the temperature and the time fusion has continued. Rubies are obtained by melting 25 parts of oxide of manganese with 1,000 of colorless strass; but the most perfect specimens are made by selecting the opaque mass often produced by the topaz mixture, which is transparent at the edges, and in thin plates red and transparent, and melting one part of this with 8 of strass. After being 80 hours in fusion it will give a fine yellowish glass; remelted with the blowpipe, the glass is like rubies of the finest water. Amethyst is made with 8 parts of oxide of manganese, 5 of oxide of cobalt, and 0.2 of purple of Cassius, to 1,000 of strass; the Syrian garnet, formerly called carbuncle, with 500 parts of glass of antimony, 4 of purple of Cassius, and 4 of oxide of manganese, to 1,000 of strass. In all these preparations success depends on a thorough pulverization and mixture of the ingredients; the use of the same sieve for sifting different mixtures should be scrupulously avoided; the fusion should be long continued at a graduated and uniform maximum temperature, and the mixture be annealed in cooling.—The researches and experiments of M. Ebelmen are of a higher order of art. He conceived the idea in 1847 of forming various mixtures with some ingredients volatile at very high heat. By the dispersion of these in the furnace the other ingredients should crystallize, as substances held in solution in liquids crystallize when these are evaporated. He thus proposed to produce the ruby, corundum or sapphire, and other precious stones. The volatile solvents or fluxes he employed were principally boracic acid and borax. The spinelle ruby, among the first minerals he imitated, was obtained by mixing together 80 parts of magnesia, 25 of alumina, 1 of chlorate of potash, and 35 of boracic acid, and subjecting 500 grammes (7,716 grains) of the compound to high temperature in the muffle of a furnace for 8 days. The crystals measured 0.197 inch on a side. Chrysoberyl was produced in crystals with faces of 0.24 inch, perfectly transparent, and scratching topaz, from a mixture of alumina 12 grammes, glucine 8.5, carbonate of lime 10, and fused boracic acid 14 grammes. The object of the lime was to form a fusible borate for holding the other ingredients in a condition favorable for crystallization. Chrysolite in well defined crystals resulted from silica 4.5, magnesia 6.15, and boracic acid 6. Transparent crystals of pure alumina, which are sapphire or corundum, and which presented the same hardness and specific gravity with this mineral, were a product of alumina thus fused with 8 or 4 parts of borax, or of 10 parts of alumina with 4 of silica and 16 of borax. M. Ebelmen employed also as fluxes the salt of phosphorus and the carbonates

of potash and of soda, all which are volatile at high temperatures, and by means of these solvents reproduced many other minerals, as he announced to the academy in 1851. His death shortly after terminated these interesting researches.—The great establishment of M. Bourguignon in Paris is the most famous manufactory of artificial gems in the world. About 100 workmen, beside many women and girls, are constantly employed in preparing and fusing the mixtures, cutting and polishing the stones, and lining the imitation pearls with fish scales and wax. The sand used to furnish the silica is from the forest of Fontainebleau; and its quality is so highly esteemed that much is exported for similar use elsewhere. The gems are such perfect imitations that they can be distinguished from genuine stones only by the closest scrutiny of those experienced in such matters. The great hardness of the natural stones it is found most difficult to imitate, and there is a want of permanency in the qualities of most of the imitations, which at last causes their true character to appear.—“A Popular Treatise on Gems,” by Dr. L. Fechtwanger, was published in New York in 1859.

GEMINI (the twins), the 8d constellation in the zodiac, so named from its 2 brightest stars, to which the names Castor and Pollux are given, and which are about midway between Aldebaran and Regulus.

GEMISTUS, **GEORGE**, surnamed **PLETHO**, a scholar and philosopher of the 14th and 15th centuries, born in Constantinople, and said to have lived to the age of 100. He held a high position at the court of the emperor Manuel Palæologus, and at the council of Florence in 1439 opposed the union of the churches of the East and the West. Being subsequently banished from his country, he found an asylum in Italy, and declared himself in favor of the Latins. While the philosophy of Aristotle was still reigning, he became an enthusiastic votary of the Platonic theories in metaphysics and natural theology, and being admitted to the court of the Medici, prompted Cosmo, the head of that family, to found his celebrated Platonic academy. His treatise in praise of Platonism inaugurated the long quarrel between the disciples of the two great masters of antiquity, which produced a profound study of their systems. Gemistus, however, mingled with the Platonic philosophy the notions of the later Alexandrian school and of the spurious writings attributed to Zoroaster and Hermes, and revived in the West that eclecticism, half Christian and half pagan, half oriental and half Greek, which flourished during the decline of the Greek philosophy at Alexandria.

GEMPAK, **SOUGITA**, a Japanese physician, one of the first in his country that became acquainted with western learning, born about the middle of the 18th century. After studying at Miako and practising medicine in the Japanese manner, he learned that the Dutch, then the only Europeans trading in Japan, were more skilful in treating diseases, because they had a

better knowledge of anatomy, and rejected the Chinese superstitions and prejudices. He therefore after long labor mastered the Dutch language, translated into Japanese Kulm's treatise on anatomy (5 vols. large 8vo., including one of well executed plates, Miako, 1778), and acquired a knowledge of the European sciences and discoveries, which he imparted to his countrymen.

GEMSBOK. See **ANTELOPE**.

GENEALOGY (Gr. *γενος*, pl. *γενεα*, race, and *λογος*, discourse), an account or history of the origin, lineage, and relationships of a distinguished person or family. Such accounts are auxiliary to historical science, and interesting not only to persons who feel a more or less natural curiosity about their ancestors, but also to the historian as elucidating the often complicated relations of dynastic families, claims and controversies of succession, &c. They are also of importance in legal cases concerning claims to inheritance, and indispensable in states in which the enjoyment of certain rights is conditioned by qualifications of lineage or descent. The practical results of genealogical researches are given in lists or accounts of ancestors and their descendants, or in pedigrees or tabular views of the members of any particular family, and of their mutual relations. They are sometimes represented in the form of a tree (*arbor consanguinitatis*), giving a clear view of the various branches of the family and the degrees of descent from the common progenitor, who is generally represented in the root, sometimes in the stem. Genealogical tables are either descending or ascending. The former are chiefly used in historical records, presenting the descendants of a certain person in the order of procreation; the latter in documents of nobility, serving to show the claims of any man or family to the titles of paternal and maternal ancestors. Sometimes both forms are used together. Persons descended one from another successively form a direct line; those descended from a common progenitor, but not one from another, a collateral line. The members forming the first 7 degrees in a direct ascending line are called in Latin *pater* (father), *avus* (grandfather), *proavus* (great-grandfather), *abavus*, *atavus*, *tritavus*, *protritavus*; the corresponding 7 members in a descending line are called *filius* (son), *neptis* (grandson), *pronepos* (great-grandson), *abnepos*, *atnepos*, *trinepos*, *protrinepos*; those above or below the 7th degree are termed respectively *maiores* (ancestors) and *posteriores* (posterity). Thus the number of the degrees does not include the person from whom we begin. The same is the case in counting the degrees of a collateral line; two cousins, for instance, are said to be at the 4th degree from each other, there being 4 persons, the cousins and their parents, beside the common progenitor or head. The collateral line embraces the agnates, or the kindred on the father's side, and cognates, or the kindred on the mother's side.—The fabulous as well as historical records of the ancient nations contain numerous genealogi-

cal lists, which sometimes connect the families of man with demigods and gods. Various books of the Scriptures, and especially those of Genesis and Chronicles, prove that the Jews were most careful in preserving their genealogical records, which were carried back not only to Abraham, their national ancestor, but up to Noah and Adam as the common ancestors of all human race. They seem to have continued to guard their genealogical documents in private or public collections during the time of the 2d temple. This practice ceased with their dispersion after the conquest of Judæa by the Romans, and even the Cohenim and Levites (descendants of Aaron and of Levi), who are still distinguished from their non-Levite brethren by the exercise of special honorary religious functions, are known as such only by being acknowledged as descendants of parents who exercised the same. The inequalities of rank and right which prevailed during the middle ages made genealogical inquiries highly important, and it was then that researches of this kind assumed the form of a science, which became closely connected with heraldry. (See HERALDRY.) The work was generally done with little criticism, the chief object being to trace the origin of families in the remotest antiquity. Similarity of names led to connections with Roman or Greek heroes, including those of the Trojan war. A similar practice had been in use among the poetical genealogists of Rome. Rûxner's "Book of Tournaments" (Simmern, 1327) is full of examples of that extravagance so common in the numerous productions of the 15th century. Critical genealogical studies were not begun before the 17th. Duchesne, Hozier, Laboureur, and others in France, Dugdale in England, Rittershusius and Spener in Germany, completed the reform of the science. Their works were followed in the 18th and 19th centuries by those of Douglas, Betham, Gordon, Burke, Imhof, Gebhardt, Gatterer, Koch, Hübner, Lewis, Hormayr, Oertel, and others. The various genealogical almanacs published at Gotha since 1763 also contain valuable information.

GENESEE, a river of W. New York, rising in Potter co., Penn., near the boundary between the two states, flowing N. W. and N. E. for 145 m. through Alleghany, Wyoming, Livingston, and Monroe counties, N. Y., and falling into Lake Ontario, 7 m. N. of Rochester. It is not a navigable stream, but abounds in varied and romantic scenery, and has 5 falls in different parts of its course. The upper falls, 8 in number within a distance of 2 m., at Portage, in Livingston co., are respectively 60, 90, and 110 feet high, and for 3 or 4 miles the river flows between perpendicular rocks 400 feet high. Just above Rochester is a series of rapids, terminating in a fall of 100 feet, and 4 m. from the mouth of the river is another fall of the same height. From the head of the rapids there is a feeder to the Erie canal, which crosses the Genesee at Rochester by a freestone aqueduct, of 9 arches, each of 50 feet span. The Genesee

valley canal, which follows the course of the river for some distance, crosses the river at Genesee Falls, near Portage, by a similar work, and the Buffalo and New York city railroad has a bridge 800 feet long and 284 feet high near the same place.

GENESEE. I. A W. co. of N. Y., drained by Tonawanda creek; area, about 486 sq. m.; pop. in 1855, 31,532. It originally formed part of Ontario co., from which it was separated in 1802. It then comprised all that part of the state lying W. of the river of the same name. The surface is almost level, and the soil, consisting chiefly of a very sandy loam, is well suited both to grain and pasture. Salt springs exist in several places, and iron, limestone, and water cement are obtained. It is a famous wheat growing district, and the Genesee flour has a high reputation. The productions in 1855 were 771,615 bushels of wheat, 437,052 of Indian corn, 299,809 of oats, 167,274 of potatoes, 41,398 tons of hay, 919,180 lbs. of butter, 105,873 of cheese, 80,056 of maple sugar, and 4,130 of tobacco. There were 46 saw mills, 22 grist mills, 1 brewery, 5 woollen factories, 2 carding establishments, 9 tanneries, 1 oil mill, 4 furnaces, 1 machine shop, 6 manufactories of agricultural implements, 61 churches, 143 school houses, and 5 newspaper offices. The Buffalo and Rochester and the Canandaigua and Niagara Falls railroads, and a branch of the Erie railroad, traverse the county. Capital, Batavia. II. An E. co. of the southern peninsula of Mich., drained by Flint and Shiawassee rivers; area, 500 sq. m.; pop. in 1850, 12,031. Its surface is undulating, covered with extensive oak-openings in the S. part, and densely wooded with pine and other timber in the N. The staples are grain, hay, and lumber. The productions in 1850 were 134,021 bushels of wheat, 128,326 of Indian corn, 84,834 of oats, and 16,964 tons of hay. There were 7 corn and flour mills, 6 saw mills, 2 iron foundries, 1 woollen factory, 2 newspaper offices, 4 churches, and 3,876 pupils attending public schools. The unfinished railroad across the state, from St. Clair river to Lake Michigan, passes through this county. Capital, Flint. Organized in 1836.

GENESEE COLLEGE. See LIMA.

GENESEE FALLS, a township of Wyoming co., N. Y., on Genesee river, about 50 m. E. S. E. from Buffalo; pop. in 1855, 1,098. It is situated in the midst of some of the finest scenery on the river, and is much resorted to by summer tourists, for whose convenience there are several hotels. It is in the immediate neighborhood of the upper falls, and on the line of the Buffalo and New York city railroad and of the Genesee valley canal.

GENESIS, the name of the first book in the Bible, denoting, in Greek, "the generation," i. e., the account of the generation or production of all things. In the Hebrew it is called *Bereashith*, signifying "in the beginning," because it commences with that word. Its history goes back to the very earliest ages of the human race,

and covers a period of at least 2,370 years; giving an account of the creation, the fall of man, the religion, arts, settlements, genealogies, corruption, and destruction of the ante-diluvian world; of the repopling and division of the earth, the dispersion of its inhabitants, the calling of Abraham, the rise and progress of the Jewish nation, &c. By most critics Moses is regarded as the author of the book of Genesis, though many suppose he derived a large part of his materials from written documents coeval, or nearly so, with the events recorded, being infallibly guided by inspiration in the entire work. This theory of the use of preëxisting documents by Moses is very ably discussed, as are all the important questions relating to the book, in Turner's "Companion to Genesis" (New York, 1841), and also in the "North American Review" (April, 1826), "Biblical Repository" (Oct. 1832), and "American Baptist Magazine" (1832). A few additions are supposed to have been made to Genesis after the death of Moses, probably by Ezra, who closed the canon of the Old Testament. The book of Genesis was distinctly recognized by Christ, and is cited in the New Testament literally 27 times, and substantially 38 times.

GENEST (in this country commonly written GENET), EDMOND CHARLES, a French diplomatist, born in Versailles about 1765, died in Schodac, Rensselaer co., N. Y., in July, 1834. Although his father was attached to the court and his sister was Mme. Campan, a lady in the service of Queen Marie Antoinette, he made himself known by his republican opinions. In April, 1789, he was appointed chargé d'affaires to the court of St. Petersburg, where his situation soon became uncomfortable; in 1791 he was notified by Count Ostermann, minister of Catharine II., that he had better not appear again at the court; and in July, 1792, he was formally dismissed. On his return to France, he was appointed ambassador to Holland; but before he had repaired to his post, he received (Dec. 1792) his nomination as minister to the United States. He arrived in April, 1793, at Charleston, S. C., where he was cordially welcomed. On May 20 he had a triumphant reception in Philadelphia; the citizens presented him with an address congratulating France upon obtaining the freedom she had helped the United States to secure. Encouraged by these demonstrations of popular feeling, Genest thought he could easily persuade the American people to embark in the cause of France, notwithstanding the proclamation of neutrality recently issued by President Washington. He openly maintained that the United States were in duty bound to side with France against England, and he bitterly denounced the American government for their want of sympathy toward the French republic. He even went so far as to fit out privateers from the port of Charleston, to cruise against the vessels of nations then at peace with the United States, and to project hostile expeditions against Florida and Louisiana, then colonies of Spain. In consequence of

these imprudent measures Washington demanded and obtained his recall; but Genest decided not to return to France, and accordingly settled in the state of New York, was naturalized, and married a daughter of De Witt Clinton. One of his grandsons was graduated at West Point and served in the U. S. army.

GENET (*genetta*, Cuv.), a digitigrade carnivorous mammal, of the family *viverrida*, inhabiting Africa, and occasionally found in southern Europe. The dentition and structural characters are the same as in the civet, the principal difference being that the anal pouch which contains the glands secreting the odorous substance is much less developed and prominent in the genet than in the civet. The common genet of Barbary (*viverra genetta*, Linn.; *G. vulgaris*, Cuv.) is of an ashy gray color, with blackish spots; the tail is nearly as long as the body, with long hair and 10 or 11 dark and light rings; the length of the body is about a foot and the tail about the same, and the height 5 inches. It is only semi-carnivorous, and will live in captivity wholly on vegetable food. The claws are sharp, semi-retractile, and well adapted for climbing; the anal secretion has a musky odor; as in other nocturnal animals, the pupil is vertical. The habits of the genet are like those of the weasel tribe; it is easily tamed, and is sometimes employed to catch rats and mice in houses; the period of gestation in captivity is about 4 months. The pale genet (*G. Senegalensis*, Fischer), or fossane, resembles the first species, and is of a reddish gray color, with pale spots above the eyes, brown bands and spots on the body and limbs, and an obscurely ringed tail. Both species prey upon small mammals, birds, and reptiles, and are not averse to fruits. Several other species are described.—The only representative of the family *viverrida* in America is the ring-tailed civet cat of Mexico and California; it is neither a civet nor a genet, though most resembling the latter, but the *bassariscus astuta* (Licht.). It is about the size of a small domestic cat, but with a more slender and elongated body, pointed fox-like nose, projecting ears, large, prominent, and lustrous black eyes, and long annulated tail. The dentition differs from that of *viverra* in having the inner process of the upper carnivorous tooth more developed, with the anterior lobe of the lower shorter. The color above is brownish yellow, mixed with gray, and white beneath; tail whitish, with 6 or 8 blackish rings; the hair on the body is short and thick, but much longer on the tail; there are 5 toes on each foot, and the sharp claws are half retractile. In its erect ears, sharp nose, and cunning look, it resembles a little fox, whence the generic name; in its movable muzzle it approaches the civet and coati. It is found from the Red river in Arkansas and San Francisco through the temperate parts of Texas, California, and Mexico, where it is occasionally seen leaping about on the trees, as lively and graceful as a squirrel; rather shy in its habits, it usually stays in or

near its hole in a tree, generally some kind of oak, whence it makes short excursions in search of small animals, birds, insects, and various nuts. This animal is easily tamed, and is often kept as a pet by the Mexicans, Indians, and Californian miners. It brings forth in confinement 4 at a birth. It is a pretty, cleanly, and playful animal, and not unfrequently seen in menageries.

GENEVA, a post village of Seneca township, Ontario co., N. Y., beautifully situated at the N. W. extremity of Seneca lake, 200 m. W. from Albany; pop. in 1855, 5,057. It is on the Auburn and Canandaigua branch of the central railroad. The principal street runs parallel with the bank of the lake, at an elevation of 100 feet, and from many of the residences terraced gardens extend to the shore. It commands a fine view of the lake and of the surrounding country. Geneva is handsomely built, and contained in 1855 about 50 stores, 1 steam flouring mill, 1 saw mill, 2 furnaces, 1 bank, 8 printing offices issuing weekly newspapers, and 8 churches (Associate Reformed, Baptist, Dutch Reformed, Episcopal, Methodist, Presbyterian, Roman Catholic, and Universalist). The Episcopal church is a fine stone structure in Gothic style, and was built at an expense of \$25,000. Hobart Free college (called Geneva college till 1852) was established here in 1824, under the direction of the Episcopalians, and in 1858 had 5 professors, beside the president, 96 students, and a library of about 8,700 volumes. Geneva medical college, founded in 1894, has 6 professors and 16 pupils. Steamers ply daily on the lake between Geneva and Watkins, touching at intermediate places.

GENEVA (Fr. *Genève*; Ger. *Genf*; It. *Ginevra*), capital of the Swiss canton of the same name, celebrated for its religious, historical, and literary associations, and its picturesque scenery, situated on the confines of France and Savoy, on the high road from Paris to Italy, at the W. extremity of the lake of Geneva, where the Rhone issues from it in two rapid transparent streams which unite after passing the town; pop. of the canton in 1850, 64,146 (84,212 Protestants, 29,764 Catholics, and 170 Jews), and of the town and its suburbs 38,000. The railway from Geneva to Lyons (distance 168½ m.) was opened March 15, 1858, and a railway to Coppet, once the residence of Mme. de Staël, was commenced in July, 1858. The river Rhone divides the town into 3 parts, one of which is an island. The largest of the other 2 parts is situated on the left bank of the river upon a site about 90 feet above the level of the lake. The Quartier de St. Gervais on the right bank is chiefly inhabited by the working classes, and is the seat of industry and trade. The most elegant part of Geneva is the new Quartier des Bergues. Since 1850 most of the fortifications have been converted into promenades and quays. The prosperity of the town having been considerably increased by the industry of the population and the affluence of strangers and travellers, the general appearance of Geneva

has been much improved within the last 20 years, and further measures are contemplated for its enlargement and embellishment. The rapid passage of the Rhone beneath the 5 bridges which connect the different parts of the town gives great animation to Geneva. The environs are extremely grand and beautiful. The glaciers of Chamouni are within a short distance. Mont Blanc, in clear weather, is a principal feature in the landscape. Among the public buildings of Geneva are the *Hôtel de ville*; the Rath museum, named after the Russian general Rath, who was born in Geneva; the museum of natural history, containing De Saussure's geological collection, Haller's herbarium, Picet's collection, the fossil plants of Brongniart and De Candolle, and Dr. Jurine's specimens of the fossils of St. Gothard; the public library, which contains many volumes of Calvin's MS. sermons and letters, letters of Beza, St. Vincent de Paul, and Rousseau. There are many institutions for the promotion of religion, science, literature, and art. An English church and a synagogue were opened in 1858, and a new Roman Catholic cathedral was erected in 1858. The principal church is that of St. Peter, which contains the monuments of Agrippa d'Aubigny and of Henri de Rohan, and in which Calvin preached. Geneva has celebrated private schools which attract many pupils from abroad, and commercial, industrial, artistic, and musical schools. The university of Geneva was founded in 1368, and reorganized in 1589 by Calvin and Beza. The college attached to it resembles the English Eton and Westminster school, and is conducted by 11 masters (*regentes*), under the direction of a rector, a principal, and the professors of the university. The studies at the university embrace belles-lettres, the different branches of philosophy and science, divinity, law, and medicine. Merle d'Aubigné, the historian of the reformation, is director of the theological school, which now numbers 40 students, 10 Genevan, and the rest mostly French. More than 1,000 youths are annually educated in the college and university; the annual salary of many of the professors hardly exceeds \$800. The excellent system of education which prevails in this institution, and its high religious and moral tone, cause it to be attended by many students from foreign countries, especially from France and Great Britain.—Geneva has long been celebrated for its manufacture of watches, jewelry, and musical boxes. The manufacture of watches dates from the 16th century, and at the end of the 18th century 6,000 persons of both sexes were employed in it. At present the number is diminished to about 8,000, though from improvements in the process of manufacturing and in the skill of the workmen, the annual production of gold and silver watches is much larger than formerly, amounting to over 50,000. There are also manufactures of velvet, silk goods, India stuffs, hats, leather, cutlery, firearms, chronometers, mathematical, musical, and surgical instruments. Geneva became a free port

in 1854; a *crédit mobilier* bank was established in 1856, and a central bank for mechanics' mutual aid societies in 1857. The transit trade is considerable, and the neighborhood of France and Sardinia gives rise to an active smuggling trade; the forwarding, commission, and banking business, especially the latter, is of great magnitude. Geneva is also the principal telegraph station and the focus of the railways of Switzerland, and the central point of the federal postal and customs union.—Calvin lived in Geneva, and Servetus was burned at the stake in the *champ de bourreau*, the ancient place of execution, outside the walls. John Knox was made a citizen of Geneva in 1558. Among the distinguished persons born in Geneva were Jean Jacques Rousseau, Necker, the naturalists De Saussure, Deluc, Bonnet, Huber, and De Candolle; Dumont, the friend of Mirabeau and of Jeremy Bentham; Sismondi the historian; and Gallatin the American statesman. Sir Humphry Davy died and was buried in Geneva. Guizot the French statesman, whose mother found an asylum in Geneva, received his early education there.—Geneva is supposed to have formed part of the territory of the Allobroges, and to have been subjected to the Romans about 122 B. C. The republic of Geneva originated in the municipal institutions of the town, to which Charlemagne granted certain privileges, subordinate, however, to the bishop, who was called prince of Geneva, and who was an immediate feudatory of the German empire. Dissensions occurred on many occasions between the citizens and the bishops on one side, and the counts of Genevois, who ruled the adjoining province of Savoy, and who claimed jurisdiction over Geneva, on the other. After the extinction of the line of the counts of Genevois, the dukes of Savoy were appointed their successors by the German emperor Sigismund (1422). Hence the claim of Savoy upon Geneva, from which the Genevans could only free themselves after several centuries by alliances with other Swiss states and by the aid of the reformation. The bishop of Geneva was expelled in 1534. Through the zeal of William Farel, the new service of the reformed religion was established in August, 1535. But the old parties, the partisans of Savoy, and the national party, most of whom were converts to the reformed religion, reappeared under new forms and fomented discord. Farel prevailed upon Calvin, who came to Geneva in Aug. 1536, to remain there. In a short time Calvin made himself the temporal as well as spiritual ruler of the town. Geneva became the leader of religion and the model of morals in Europe, the home of literature and learning, and the metropolis of Calvinism. An attack of Charles Emanuel of Savoy upon Geneva (Dec. 12, 1602) was gallantly repelled, and the victory then achieved is still commemorated. The independence of Geneva was solemnly recognized by the house of Savoy in 1754. In 1798 the town was occupied by French troops and incorporated with France as a part of the depart-

ment of Leman. After the overthrow of Napoleon it joined the renewed Swiss confederacy, (March 20, 1815), and several places which had formerly belonged to France and Savoy were added to its territory. A new and more liberal constitution was adopted, May 24, 1847, to remain in operation until 1862. Geneva was the first Swiss state to introduce trial by jury (1844), and exerted a liberal influence upon the national councils in the promulgation of the federal constitution in 1848. The canton sends 8 delegates to the federal council of the cantons, and furnishes to the Swiss confederacy a contingent of 2,199 men, 280 horses, 20 pieces of artillery, and about \$9,000 in money. The annual revenue and expenditures of the canton average respectively about \$300,000. The constitution guarantees religious freedom to the Roman Catholics. The Protestant churches are governed by a consistory, which is elected for 4 years, appoints an executive committee of 5, and is composed of 25 lay members and 6 clergymen. The *compagnie des pasteurs*, which comprises all clergymen and professors of theology, presides over the religious instruction of the Protestant population, and controls ecclesiastical appointments. The administration of education is in the hands of the government, but the parishes are called upon to contribute toward its support. The predominant language is French. The peasantry speak a *patois* which resembles somewhat that spoken in the neighboring districts of France, Savoy and the Pays de Vaud.

GENEVA, LAKE OF, OR LAKE LEMAN (Ger. *Genfer-See*; Fr. *Lac de Genève*; anc. *Lacus Lemanus*), one of the largest lakes of Europe, extending in the form of a crescent, with its horns towards the S., between Savoy on the S., and the Swiss cantons of Geneva, Vaud, and Valais. Its N. bank forms an arc about 53 m. in length, without reckoning the sinuities; along its S. shore it measures 46 m.; and its breadth varies from 8 or 9 m. in the middle to 4 m. near the E. and 1 m. at the W. extremity; area, 82 sq. m. Its greatest depth is nearly 1,000 feet; its average depth is from 300 to 600 feet. Its elevation above the sea is 1,150 feet, but in summer, when the Alpine snows melt, it sometimes rises as much as 6 or 8 feet higher. At other periods it presents in particular parts of the lake, most commonly near Geneva, the curious phenomenon of a rapid rise and fall of from 2 to 5 feet in the course of 25 minutes. These changes of level, called *seiches*, have never been fully accounted for, but are supposed to be owing to the unequal pressure of the atmosphere upon different parts of the surface of the water. They are independent of the wind, and most frequent when the clouds are low and heavy. The lake is never frozen over, though ice forms in winter near its lower extremity. Its waters are pure and of a bright blue color, like those of the Mediterranean. The Rhone enters it at the E. end, a dark, muddy stream, and leaves it near Geneva perfectly pellucid and of the finest

sure me. The debris brought down by this stream are deposited around the upper end, and have made considerable encroachments upon its basin. Port Vallais, 1½ m. inland, was formerly situated on the shore, and the waters are said to have extended even as far as Bex, 13 m. up the Rhone. From Savoy Lake Geneva receives the Dranse, and from Switzerland the Venoge and the Vevayse. It has fewer fish than other Swiss lakes, but contains excellent trout, pike, carp, and perch, and a kind of salmon. Steamers ply daily between Geneva at the W. and Villeneuve at the E. end. The scenery, though lacking the dark grandeur of the bay of Uri in Lake Lucerne, and the sunny softness of some of the Italian waters, is an unending theme of admiration to travellers. On the N. are beautiful vine-covered hills, dotted with cheerful villages; opposite rise the abrupt cliffs of the Chablais, rearing their heads 5,000 feet above the lake. The majestic Alps are seen beyond them through the openings, and the shadow of Mont Blanc sometimes lies upon these waters. On the E., between the lofty summits of the Dent de Morcles and the Dent du Midi, about 9,000 feet high, a narrow pass opens into the Valais, while at the W. end the lake narrows almost to a point, and terminates among the pleasant slopes on which stand the city and suburbs of Geneva. The lake of Geneva is famous in literary history as the scene of the *Nouvelle Héloïse*, and for the abode in its vicinity of many celebrated authors, among whom may be mentioned Voltaire, Rousseau, Gibbon, Madame De Staël, Byron, and Shelley.

GENEVIÈVE, SAINT. I. The patron saint of Paris, born in Nanterre in 419 or 422, died in Paris in 512. When St. Germain, bishop of Auxerre, preached in Nanterre, he was struck by her air of sanctity, and by his counsel she entered a convent. Living in Paris in 449, she is said to have predicted the invasion of Gaul by the barbarians of Asia; and when 2 years later Attila passed the Rhine and terrified Paris, she exhorted the citizens to courage and piety, assuring them that the city would not be attacked. The prophecy, justified by Attila's sudden departure, caused her to be regarded with reverence and affection by the Parisians. Such was her renown that Simeon Stylites at Antioch in Syria was accustomed to ask every one from Gaul that he saw for news of her. She passed her life in austerities, prayer, and pious works, and many miracles were attributed to her agency even after her death. A church dedicated to her was begun by Louis XV., but as it had not in 1791 been used for Catholic worship, it was adopted by the national assembly for the Pantheon. In 1852 this church was consecrated to St. Geneviève, whose festival is celebrated in it on Jan. 8. II. Duchess of Brabant, and countess palatine, lived early in the 8th century. She is the theme of many mediæval traditions, according to which she was falsely accused of adultery, lived 6 years alone in a wild forest, and was then dis-

covered by her husband, who was following the chase, and who was reconciled with her by finding the nuptial ring still worn on her finger.

GENGHIS (or ZINGIS) KHAN, an Asiatic conqueror, born about 1160, died in Aug. 1227. His father was the chief of a horde, consisting of numerous families or clans, and tributary to the khan of eastern Tartary. When born, the child had his hand full of blood; and pleased by the interpretation of this sign as a prediction of conquest and glory, the father procured for Genghis, or, as he was then called, Temudjin, an able teacher, who soon developed in him a talent for government and war. Temudjin was only in his 14th year when he succeeded his father, and after some reverses he made himself master of the neighboring tribes, 70 of whose chiefs are said to have been thrown into kettles of boiling water at his command. Against a league of more numerous tribes he was also victorious, but was unable to subdue them, and compelled to invoke the protection of Vang or Ung, the great khan of the Kerait Tartars. Temudjin supported him in his turn in different wars, and was rewarded with the daughter of the khan in marriage. But his bravery, liberality, and success soon made him an object of envy and fear; a war ensued, in which the khan lost his army on the battlefield, and his life while in flight. Another enemy of Temudjin, Tayan, khan of the Naiman Tartars, met with a similar fate in and after the battle of Altai, which gave Temudjin a great part of Mongolia and the capital Karakorum. In the next spring he held a great assembly of his nation at Blun-Yuldad, his capital, where the representatives of all the hordes appeared and proclaimed him their great khan. It was then that, obeying the words of a *shaman* (inspired man), who promised him the conquest of the earth, he adopted the title of Genghis (greatest), and gave to his people that of Mongols (the bold). He now organized their civil and military system, and laid down a code of laws which is still known in Asia under his name, and is based upon the belief in one God and the monarchy of one great khan, to be elected from the reigning family by the *kurultai*, or assembly of the nation. It grants great privileges to the nobles, allows polygamy, forbids to conclude peace except with the vanquished, and commands the delivery of arms into the hands of the government in times of peace, and when no national hunts are held. He granted equal rights to every religion, and admitted men of talents or merit to his court, whatever their creed. Appreciating the wisdom of other nations, he caused many celebrated books to be translated from foreign languages. But the ambition of the conqueror, surpassing the wisdom of the lawgiver, prompted him to new expeditions. The annexation of the Ugrian or central Tartars served to complete the conquest of Tartary; he now commenced that of China, passed the great wall, vanquished the opposing armies, devastated the country, and took, in 1215, Yeh-king (now Pe-king) by

assault. This great city was pillaged and consumed in a month by fire. Giving the command in the East to his son Tutshee, he now turned his sword to the West, crushed some revolted tribes and their allies, and took a bloody revenge for the murder of his ambassadors on Mohammed, sultan of Khovaresmia (now Khiva). An army of 400,000 men and the mighty cities of Bokhara, Samarkand, and others, opposed him in vain; the Mongols conquered and devastated the whole country; the cities were destroyed, and with them immense treasures of eastern science and art; and numberless inhabitants were slaughtered or carried away as slaves. Another Mongol army marched against Kaptshak, and took Derbend on the shore of the Caspian sea; another reduced Iran and Astrakhan, and, after a bloody battle on the Kalka, southern Russia; another continued the conquest of China and subdued Corea. The countries N. W. of India were also conquered, and an expedition against that country was begun. In this he is said to have shared the fate of Alexander the Great in a similar undertaking; after some victories the army refused to advance further, and he was compelled to return amid terrible difficulties. He now turned his arms against the kingdom of Tangut, passed the desert of Gobi in winter, and defeated 300,000 men on a frozen lake; the Tangut dynasty was extirpated. He was meditating a war against the Niudjes when death ended his career. He was buried in his native home, and his funeral was celebrated with songs, and, some historians say, with a hecatomb of beautiful young girls. His empire was divided among his 4 sons, Oglutai, chosen great khan, Djagatai, Tului, and Tutshee, whose armies soon completed the conquest of China, overthrew the caliph of Bagdad, made the sultan of Iconium tributary, and penetrated as far as the Oder and the Danube.

GENII, among the Romans, supernatural beings, corresponding to the demons (*dæmones*) of the Greeks, and analogous to the guardian angels of Christians. They were regarded as accompanying men from their birth through life as a kind of second or spiritual self; and every living thing and every place had its genius. Those of women were called Junones. It was customary for every one on his birthday to worship his genius as *sanctus et sanctissimus deus*, with libations and flowers. The collective Roman people had its genius, which was sometimes represented on coins.—The genii or djinns of the East are regarded as an intermediate class of beings between angels and men, but inferior in dignity to both, of pre-Adamite origin, created of fire, and capable of becoming invisible, or assuming the forms of men, brutes, or monsters, at pleasure. They eat and drink, are subject to passions and death, but may live for centuries. Their principal abode is in the Kaf chain of mountains, which is believed to encompass the earth, and to which they were compelled to retreat by an ancient Persian king who was a powerful necromancer. Djinnestan

is the common name of this ideal region. They also frequent baths, wells, ovens, ruined houses, seas and rivers, cross roads, and market-places. Their prince or chief is Eblis, so called from his despair, who was at first one of the angels nearest to God's presence, and was called Azazel, but was cast out of heaven for refusing, at the command of God, to pay homage to man at the time of the creation. His reply to the command was: "Thou hast created me of fire, and hast created him of earth." Some of them are believers in Islam, others infidels; some are good and some evil; and of both classes the Arabs stand in great awe. They pervade the earth, and rise to the firmament, where on the confines of the lowest heaven they listen to the conversation of angels respecting future things, and are thus enabled to assist diviners and magicians. Shooting stars are believed to be arrows shot by the angels against genii who transgress their limits. The peris, or fairies, are beautiful female genii, who believe in God and Mohammed his prophet, and seek to do good on the earth. The ghouls are a subordinate class of evil genii, haunting deserts and burial grounds, and killing and devouring men and women that fall in their way. The evil genii delight in mischief for its own sake, raise and direct whirlwinds, and dry up the springs of the desert. When the Zobaah, a whirlwind that raises the sand in the form of a pillar to a lofty height, sweeps over the desert, the Arabs, who believe it to be caused by the flight of evil genii, cry out: "Iron! iron!" of which metal the genii are believed to have great dread; unlike the Irish peasantry, who believed that whirlwinds of dust were raised by the fairies, and on such occasions used to raise their hats and say: "God speed you, gentlemen!" During the month of Ramadan the genii are believed to be confined in prison.

GENITIVE, in grammar, the second case in the declension of nouns and pronouns, generally indicating the relation expressed in English by the preposition *of*. It is distinguished as subjective or objective, the former denoting the source and the latter the object of the idea contained in the qualified noun; thus, respectively, "the deeds of heroes," and "the fear of God." There is also a partitive genitive, following and completing the meaning of adjectives and adjective pronouns, as "full of wine." The English possessive case, marked by the addition of the letter *s* preceded by an apostrophe, as "a bird's flight," is an instance of the genitive.

GENLIS, FÉLICITÉ STÉPHANIE DUOREST DE, countess, a French authoress, born near Autun, Jan. 25, 1743, died in Paris, Dec. 31, 1830. She had a taste for music, acquired great proficiency on the harp, and was able to perform on the piano and 6 other instruments; but her education was almost entirely neglected, and she thought of nothing but amusement. When scarcely 15 years of age, she was married to Count Brulart de Genlis, a friend of her father who had fallen in love with her on seeing her portrait. Aaham-

ed of her ignorance, she then devoted herself to study. By the influence of her aunt, Mme. de Montesson, who had been secretly married to the duke of Orleans, she was in 1770 appointed a lady in waiting in the household of the duchess de Chartres; became soon afterward governess of the daughter of that princess, and was formally nominated in 1783 by the duke "governor" of his three sons, the eldest of whom was afterward King Louis Philippe. Such a title given to a woman gave rise to no little scandal, and the influence she subsequently exercised upon the political course of her employer, the notorious Philippe Egalité, seemed to warrant the most injurious suspicions. During her governorship she published several works devoted to the moral education of her pupils—the *Théâtre d'éducation*, *Annales de la vertu*, *Adèle et Théodore*, *Les veillées du château*—which were generally well received by the public, and were highly praised by Gaillard, La Harpe, and other eminent critics. During the first years of the revolution she proclaimed her liberal opinions, and is said to have been the principal adviser of Philippe Egalité. She was obliged, however, to emigrate in 1792, and retired for a while to Switzerland, and then to Prussia. Amid all her troubles, she neglected no opportunity of mingling in worldly pleasures, and acquired a special notoriety at Berlin. During this period of her life she wrote and published several works, among which were her *Mémoires*, *Les petits émigrés* (new and revised edition, 1858), *Le petit La Bruyère*. In 1800 she returned to France, and was well received by the first consul; she was allowed handsome apartments at the arsenal and a pension of 6,000 francs, to which the wife of Joseph on his accession to the throne of Naples added an annuity of 8,000. In return for this, she had to write twice a month to Napoleon, and communicate to him her opinions and observations on politics and current events. She was convinced, and indeed declared, that these communications influenced the course of Napoleon in many important circumstances. This period of comparative repose and prosperity was also one of literary activity; she gave to the public, among other works, *Mlle. de Clermont*, the best of her performances, which ranks among standard novels in the French language, *La duchesse de La Vallière*, *Mme. de Maintenon*, and *Le siège de La Rochelle*. In 1814, although she had frequently, and with good reason, called Napoleon her benefactor, she went over to the Bourbons, but was coldly received. She met with little more encouragement from the Orleans family, who contented themselves with paying a small pension to their old "governor." Her temper meanwhile, which never had been very gentle, became sullen and unmanageable; her misanthropy increased with years; but her wrath was especially directed against the philosophers of the last century; she published amended editions, with critical notes, of several works of Rousseau and

Voltaire, and she even contemplated a similar "emendation" of the *Encyclopédie*, but, appalled at the magnitude of the undertaking, gave it up, and turned her pen against the most popular contemporary authors. Mme. de Staël, Byron, Sir Walter Scott, and Lamartine, were among the objects of her attacks. She was 60 years of age when she published her historical novel *Jeanne de France*, and over 80 when she completed her personal *Mémoires*, in 10 large 8vo. vols. In her latter years the once dashing fashionable lady had become a repulsive old woman, dressing in a slovenly manner and living in a gloomy apartment in one of the suburbs of Paris. Before her death, she witnessed the elevation to the throne of her pupil Louis Philippe; but estranged as she had been from him for long years, this was no joy to her. One of the most prolific writers in the French language, her admirers boasted that she had written as many volumes as Voltaire, if not more.

GENNESARETH, LAKE OF, called also the sea of Cinnereth, the sea of Galilee, the sea of Tiberias, and by the Arabs Bahr Tubariyeh, situated in Palestine, 90 m. N. of the Dead sea, and traversed by the river Jordan. It lies amid a circle of hills 620 feet above the level of the Mediterranean, occupies the bottom of a great basin of volcanic origin and of an oval form, and is about 18 m. long and 6 m. wide. There is little variety or beauty in its natural features, and the interest connected with it springs from its associations, especially from the fact that much of the public life of Christ was spent on its shores. Populous cities and villages then flourished around it, as Magdala, Capernaum, Chozazin, the two Bethsaidas, Gamala, and Hippos; and multitudes followed him as he taught along its beach or on the bordering heights. Four at least of the apostles were fishermen on this lake. The borders are now nearly desolate, and the fisheries neglected.

GENOA (Ital. *Genova*; Fr. *Gènes*; anc. *Genua*), an administrative division of the kingdom of Sardinia, bounded N. by Alessandria, E. by Parma and Modena, S. by the Mediterranean (gulf of Genoa), and W. by Savona; area, 1,250 sq. m.; pop. in 1857, 570,492. It is divided into the provinces of Genoa, Chiavari, Novi, and Levante. The duchy of Genoa, as constituted by the congress of Vienna, included the present division of Savona, and, stretching in a semicircle around the head of the gulf, was divided into the Riviera di Levante (eastern coast), and Riviera di Ponente (western coast). It is traversed by the Ligurian Apennines. The mountains rise to a height of about 5,000 feet, forming abrupt declivities toward the sea, and sloping down gradually toward the N., where the Scrivia, Trebbia, and other rivers flow to the Po. The streams flowing into the sea, the Magra and others, are insignificant. The sea forms numerous bays, among others those of Rapallo and Spezzia. The climate is mild and mostly healthy, but piercing N. winds and exceedingly hot S. winds are not unfrequent. The

summits of the mountains are bare; the valleys as well as occasional terraces on the slopes produce grains, wine, oranges, almonds, figs, chestnuts, &c. Salt, marble, asbestos, alabaster, and gypsum are produced. The inhabitants, mostly descendants of the ancient Ligurians, are a robust, well formed, active, and industrious people. Their common dialect is peculiar, and hardly intelligible to other Italians. Many of them are engaged in iron works, tanneries, paper mills, and cloth factories.—GENOA, the capital of the duchy, not undeservedly surnamed *la Superba*, is situated on the N. extremity of the gulf of the same name; lat. 44° 24' 20" N., long. 8° 55' 55" E.; pop. in 1857, 119,610. It is surrounded by a double wall, the smaller encircling the inner city, by ramparts and extensive outworks, detached forts, and redoubts, which make it one of the best fortified cities of Europe. Its large semicircular harbor is defended by two converging moles, the eastern or old, and the western or new. Near the former are the custom house and its environs (*dogana*), and the so called free harbor (*porto franco*); near the latter a lofty lighthouse and the quarantine; on the N. side of the harbor is the arsenal with a state dock and the bagnio. Viewed from the harbor, the city, rising like an amphitheatre, with its churches, palaces, promenades, and gardens, with its encircling fortifications, and with the bare summits of the Apennines and the ice-covered peaks of the Alps behind, offers one of the grandest and most picturesque sights in the world. The streets are mostly narrow, irregular, and steep; many are inaccessible to carriages. Some, however, are straight and handsome. But Genoa is principally famed for its palaces. They are rich in works of sculpture and painting, as are also the churches and chapels. Of these there are about 250, the most conspicuous of which are the Duomo or cathedral of San Lorenzo, the San Siro, Annunziata, Santa Maria di Carignano, San Matteo, Sant' Ambrogio, and San Stefano. Some are the works of private munificence, and some owe their foundation to the earliest times of the Genoese republic. The city is also adorned with various public places (*piazze*), with numerous historical monuments, including statues of Columbus, Andrea Doria, and other distinguished natives, with theatres, promenades, collections of art, and institutions of benevolence and learning, including a university, an academy of fine arts, a naval school, a school of medicine, an institution for the deaf and dumb, a botanical garden, rich libraries, and hospitals. It is the seat of an archbishop, a governor, and various high civil, military, and naval officers; it has a dock yard, an exchange, and several railroad depots, being connected by rail with Turin, Milan, and other places. Magnificent highroads lead over the mountains in every direction. Numerous steamers maintain communication with Marseilles, Leghorn, and other cities of the Mediterranean. Genoa is an important naval

station, and the chief commercial emporium of Sardinia; it also imports for Lombardy. Its exports consist chiefly of fruits and home manufactures, silk and velvet goods, ribbons and artificial flowers, wax, cloth, hats, soaps and perfumes, macaroni and preserves, and various articles of ivory, alabaster, coral, marble, and precious metals. The imports in 1855 were valued at \$48,000,000, and the exports at \$31,000,000.—The history of Genoa may be traced back in legendary traditions to a time preceding the foundation of Rome. Livy mentions it first, at the beginning of the 2d Punic war, as a town in friendly relations with the Romans. It was subdued and partly destroyed during that war by a Carthaginian fleet, which sailed from the Balearic isles under the command of Mago; the Romans rebuilt it, and it afterward became a Roman *municipium*. In the time of Strabo it was an emporium for the produce of the interior, exchanged by the Ligurians for the wine and oil of other parts of Italy. After the fall of the western empire it suffered greatly from the invading Goths, was taken by the Lombards in the 7th century, and conquered from them in the 8th by Charlemagne, who appointed a count for the government of the coast of Liguria. After the dismemberment of the Frankish empire, it became independent, and shared the fate of the Lombard cities, participating in their bloody struggles during the long contest for the iron crown of Lombardy, between the emperors of Germany, the Berengarii, and others. Having been pillaged in 935 by the Saracens, who at that time infested the shores of the Mediterranean, Genoa strengthened its navy, made an alliance with Pisa, and finally succeeded in expelling the Mohammedans from the islands of Corsica, Capraja, and Sardinia (1016-'21), of the two former of which it kept possession. An expedition to Africa, undertaken in 1088, was no less successful. Genoa was then governed by consuls, the first of whom are recorded in the latter part of the 11th century, and was already formidable at sea, preceding the Venetians in controlling the commerce of the Levant. But the maritime importance of the Genoese roused the jealousy of their commercial neighbors, and they had to struggle for the maintenance of their power in the western part of the Mediterranean against the rival republic of Pisa, and in its eastern part against Venice. The hostilities with the former commenced in the year 1070. The Genoese had a share in the glory and success of the first crusaders, their services being rewarded with a part of the coast of Palestine, including Acre. After the 2d war with Pisa (1118-'32), they undertook an expedition against the Moors of Spain, with a large fleet carrying a land force of 12,000 men, conquered the island of Minorca (1146), Almeria in the province of Granada (1147), where they found immense booty, and, in concert with the Catalonians, Tortosa (1148). Their power was also rapidly extended over the coast of the Mediterranean; before the close of the 12th cen-

ture they were masters of Monaco, Nice, Monterrat, Marseilles, and nearly the whole coast of Provence. The 3d war with Pisa commenced in 1162, and continued for nearly a century. The 4th, in 1382, opened with a great naval victory of the Genoese over the Pisans, who lost 3,000 killed and 13,000 prisoners, most of whom were doomed by the cruelty of the victors to perish in chains; it was concluded by the conquest of Elba, and the destruction of the harbor of Pisa, under Corrado Doria (1290). Thus peace was conquered, and the might of the rival republic destroyed. No less severe had been the struggle with Venice since the conquest of Constantinople by the Franks (1204), which was achieved under the lead and greatly to the profit of that republic. Having assisted Michael Palæologus to reconquer the capital of the Byzantine empire (1261), the Genoese were rewarded with the suburbs of Pera and Galata, and the port of Smyrna, which possessions made them the masters of the Black sea. After several naval battles a truce was concluded with Venice in 1271. On the termination of the wars with Pisa a mighty Genoese fleet crossed the Adriatic, and won a great victory near Curzola, where 84 Venetian galleys were taken or burned, and 7,000 captives made, among them the admiral Dandolo. This was followed by a treaty of peace (1299), which surrendered the commerce of the Black sea to the exclusive dominion of the Genoese, whose flourishing colonies and factories defended by forts soon lined all its coasts. Kaffa, or Feodosia, in the Crimea, conquered by them, became one of the finest commercial cities of Europe. Favored by the friendship and the indolence of the Byzantines, they carried on the commerce of the East, including India, through the Euxine and the Caspian seas. A new war with Venice broke out in 1346, in which the Genoese were victorious in a sea fight, in sight of Constantinople, but were beaten in another near the coast of Sardinia. To escape the consequence of this defeat and the perils of intestine commotions, they subjected themselves to the duke of Milan, Giovanni Visconti, whose yoke, however, they soon shook off. Having recommenced the war (1377), they took Chioggia, besieged Venice, and nearly reduced it, when two of its citizens, Vettor Pisani and Carlo Zeno, revived the spirit of the besieged, created a new fleet, blockaded Chioggia, and compelled the Genoese to surrender. The peace of Turin (1381) terminated the wars of the two greatest maritime republics of the middle ages; it was preserved, with slight interruptions, during the decline of both, caused particularly by the conquests of the Turks in the East, and the maritime discoveries in the West. Giustiniani and his companions strove heroically, but in vain, to save the great bulwark of Christendom, Constantinople, and the interests of Genoa (1453); and Mohammed II. revenged himself by stripping the republic of all its possessions in the East; even the com-

mercial access to the Euxine was soon closed by the Turks.—During all this growth and decline of the republic, its internal commotions, caused by the parties of the plebeians and patricians, and the subdivisions of the latter, had been a source of continual perils and distractions. Having been governed by consuls till 1190, then by *podestàs* (annual magistrates, who were chosen from foreign cities) till 1270, it fell under the usurpation of Oberto Spinola and Oberto Doria, the "captains of liberty," who reconciled the lower classes, and maintained their power till 1291. A new change was the institution of the council of 12 members, subsequently of 24, 12 nobles and 12 plebeians. The feuds and even fights of the democratic and aristocratic parties, the Guelphs and Ghibellines, were meanwhile continuous. The latter faction, whose chiefs were the Dorias and Spinolas, was at last overcome and exiled by their opponents, headed by the Fieschi and Grimaldis, but afterward found means of returning. These party struggles assumed the worst shape in the first half of the 14th century. To remedy these evils the dogate for life was instituted (1389), with the exclusion of the nobles of both parties. But neither this nor the addition of councils was sufficient to give peace to the distracted state; new contentions arose with new families; there were doges and anti-doges; some were exiled, others forced upon the people. The Viscontis of Milan, and at a later period the kings of France, availed themselves of these dissensions to take possession of the republic. Francis I. held it during the first part of his wars with Charles V., but in 1528 the celebrated admiral Andrea Doria delivered the state from the French, and established a new constitution, which lasted to the end of the republic. The new form of government was strictly aristocratic; a roll of families both plebeian and patrician was formed, the nobility divided into the old and new; the former comprised the Grimaldis, Fieschi, Dorias, Spinolas, and 24 others distinguished by age, honors, or riches, and the latter 487 houses, to which new families could be added; the doge was elected for 2 years, and both branches of the nobility could aspire to this dignity. But the power of the state had long since departed; its conquests, colonies, and maritime stations were lost one after another; the last of them, Corsica, revolted in 1730, and was ceded to France in 1768; the commerce of the seas and of the East passed successively through the hands of the Portuguese, Spaniards, Dutch, and English; the flag of Genoa was insulted with impunity by the Mohammedan pirates of northern Africa, and its naval force was a mere shadow of the ancient fleets which awed all the shores of the Mediterranean and Black seas. The single bank of St. George (*compersa di San Giorgio*), which had been founded in 1407, still maintained its dignity and importance as an institution for loans and deposits, to which even foreign states, and particularly Spain, were greatly indebted. When in 1796 the French

had conquered the neighboring territories, Genoa strove in vain to sustain itself by neutrality. A rising of the democratic party was suppressed, after several days of bloodshed, by the nobles, who were assisted by the poorest of the population; but the French directory took the part of the democracy, and demanded a change in the constitution. This demand was supported by an army, and finally agreed to. The French garrison was taken into the city, and the state changed into the republic of Liguria, with a constitution like that of France, and some additional territory. In 1799 Genoa, under Masséna, sustained a siege by the Austrians and English, and was compelled to capitulate to the former, who were obliged, however, to give it up after the battle of Marengo (1800). The victorious Bonaparte, as first consul, gave it a new and less democratic constitution, which was soon abolished on the establishment of the French empire. After the coronation of Napoleon at Milan, the last of the doges, Durazzo, repaired to that city, and expressed the desire of the people for the change; and the decree of June 4, 1805, merged the republic in the empire, to form the 8 new departments of Genoa, Montenotte, and the Apennines. The bank of St. George, whose credit had greatly suffered by repeated loans to the state, was abolished, and the debts of the latter transferred to the account of France. In 1814 Genoa was occupied by the English, with whose permission the ancient constitution was reestablished. But the congress of Vienna (1815) annihilated the independence of Genoa, giving it as a duchy to Sardinia. In 1821 it joined for a moment the revolutionary movements of Italy. There was nothing remarkable in its history in 1848, but at the end of March, 1849, after the defeat of Charles Albert at Novara, and the conclusion of a truce with the Austrians, a revolutionary outbreak took place, the national guards occupied the forts, and the garrison was compelled to withdraw. A provisional government, under Avezzana, Morchio, and Reta, was formed, and the independence of the republic was proclaimed. But a large body of Sardinian troops, under Gen. Della Marmora, soon appeared before Genoa; a bloody struggle ensued, and the forts and principal points of the city were taken by the royal soldiery. In the meanwhile a deputation was sent to Turin, which returned with the amnesty of the king, excluding, however, the chief leaders of the movement, who had withdrawn on board the U. S. steamer Princeton. On April 10 Genoa was disarmed, and the monarchical government restored. During the Italian war of 1859, the city served as the landing place of the French troops arriving by sea.

GENOUE (originally GENOUD), ANTOINE EUGÈNE DE, a French journalist, born in Montélimart in Feb. 1792, died in Hyères, April 19, 1849. He began his career as a political writer by contributing to the royalist journal *Le conservateur*. In 1820 he founded the journal *Le défenseur*, and in 1821 he bought the *Étoile*,

which has since born the name of *La gazette de France*. He abandoned his intention of entering the priesthood when, in 1822, he was ennobled by Louis XVIII. In 1835, however, after the death of his wife, he returned to his original plan, took orders, and began to preach in Paris. The archbishop of Paris soon ordered him to quit either preaching or journalism, and he chose the former alternative. In 1846 he was elected by the city of Toulouse member of the chamber of deputies, and in that body acted with the legitimist opposition. He differed, however, in many points from the legitimist party in general, defending universal suffrage, national representation, and legitimacy allied with popular sovereignty. In Feb. 1848, at the outbreak of the revolution, he spoke against the establishment of a regency, and allied himself with the revolutionary party in order to attempt a restoration of the Bourbons by means of a general vote of the people. When he saw that his efforts were fruitless he retired from public life. The bold advocacy of his principles in the *Gazette de France* involved him in 63 lawsuits, which cost him more than 100,000 francs. He wrote a *Histoire de France* (16 vols., Paris, 1844-'7), and published a French translation of the Bible, and of the "Imitation of Christ," an edition of the complete works of Malebranche (1837), and of the select works of Fénelon (1842), and of Bossuet (1845).

GENS D'ARMES, originally in France the whole body of armed men (*gens armata*), but from the 12th century applied particularly to armed men of noble rank, who are usually called in the documents of the time *militēs* in Latin, and *chevaliers* in French. The term assumed a more precise signification under Charles VII., designating the 100 men of rank who formed the *élite* of each *compagnie d'ordonnance*. The *gendarmérie* acquired great celebrity under Charles VIII., Louis XII., and Francis I., especially in the wars of Italy. It declined in the 16th century, and the name had ceased to be much in use, when during the revolutionary period it was given to a corps composed of infantry and cavalry employed to protect the roads and streets and to enforce the orders of the police. The duties of rural police in France are performed by mounted gens d'armes, selected from the army. They are each paid \$400 per annum, out of which they provide a horse and a handsome uniform.

GENSERIO (from *Gaiseric*, prince of the spear), a Vandal conqueror, bastard brother and successor of Gonderic, died in 477. The Vandals had passed the Alps and the Pyrénées, and devastated and conquered the greatest part of Spain. In 429, when the weak and debauched Valentinian III. occupied the throne of the crumbling western empire, they were called to the province of Africa by Boniface, the governor, who had been induced by intrigues and the fear of a rival to betray his master. Eager for conquest, these northern barbarians prepared a fleet, and were ready to embark when the unexpected

attack of Hermanric, king of the Suevi, and the ravages of this people on the possessions of the Vandals, delayed their departure. Having routed the Suevi in a bloody battle, Genseric embarked his forces, and crossed the straits of Gibraltar. Alani and other barbarian tribes had swelled their numbers to 50,000, and Genseric tried to magnify their appearance by the appointment of 80 chiliarchs; the Moorish inhabitants of the Atlas mountains, so long oppressed by the Roman governors, and the Donatists, driven to despair by the persecutions of the orthodox church, joined them in Africa. Boniface too late repented of his crime; vanquished in battle, he retreated to Hippo Regius (now Bona in Algeria), but being unable to maintain himself he sailed to Italy. The whole of Africa west of Carthage was ceded by a treaty to the Vandals; but that city was also soon taken by surprise, and made the capital of the Vandal empire, which now extended over the whole coast, and by piratical expeditions was established in parts of Italy, Sardinia, and Corsica. The attacks of the Huns in the north of the Roman empire made these aggressions on its southern provinces easier, and it was Genseric who invited Attila to his fatal march to Gallia (451). Rome happily escaped the hands of the Huns, but its weakness and a series of crimes soon gave it into those of the Vandals. Invited, as is said, by Eudoxia, widow of Valentinian III, who wanted to avenge the murder of her husband by Maximus, Genseric crossed the Mediterranean, sailed up the Tiber, took Rome, pillaged it for 14 days, carried away Eudoxia and her daughters, one of whom he gave to his son Hunneric, and the Roman treasures and captives were sent to Carthage. Thus, after 600 years, a Vandal sword avenged the not less barbarous destruction of Carthage by Scipio. All the shores of the Mediterranean, from Asia Minor and Egypt to the straits of Gibraltar, were now infested by the ravages of the Vandals. A fleet, sent by the emperor Majorian (457) to check these ravages, was destroyed in the bay of Carthage; nor was another sent by the Byzantine emperor Leo (468) more successful; and Genseric reigned victoriously until his death. He was of middle stature, lame of one leg in consequence of a fall from a horse, slow and cautious in his speech, cunning, treacherous, cruel, ambitious, unscrupulous, an able general, and a skillful ruler. His share in the destruction of the Roman empire ranks him as a conqueror immediately after Alaric the Goth and Attila the Hun. He professed the Arian creed.

GENTIAN, in medicine, the root of the plant *gentiana lutea*, growing wild in the mountainous portions of Europe, and imported into the United States from Germany. Some other species of the genus are found in certain localities, and are also used for medicinal purposes. One of these, known as the blue gentian (*G. Catesbeii*), is found in the grassy swamps of N. and S. Carolina, and so closely resembles in its proper-

ties the officinal gentian, that it is used at the South, and is introduced into the late catalogue of the U. S. pharmacopoeia. Its flowers are blue; those of the foreign gentian are yellow, which is also the color of the powdered root. Both have at first a sweetish taste, followed by intense bitterness; and both yield their medicinal qualities to water and alcohol. The Swiss macerate the plant in cold water, and the sugar it contains causing it to ferment on standing, they distil from it a spirituous liquor, bitter and unpleasant, but much used by them. As a tonic it has been used from remote times, and the name is said to have been given to it from Gentius, a king of Illyria. It is found as an ingredient in many of the ancient receipts transmitted from the Greeks and Romans. It is still used in a great variety of complaints, its effect being to strengthen digestion, excite the circulation, and increase the warmth of the body; but it is liable to disagree with the stomach, exciting nausea and irritating the bowels, and cannot therefore be administered without due reference to the condition of these organs. It is given in powder, in extract, infusion, tincture, or sirup. The powder has been used as an external application to ulcers.

GENTILES (the equivalent of the Heb. גוים and Gr. ἔθνη), the name by which the Jews distinguished all the other nations or *gentes* of the world from themselves. In their use of it, it corresponds to our word heathen; for all who were not Jews, and circumcised, they regarded as gentiles or heathen, and as such excluded from all the religious privileges and relations by which they were so greatly exalted. In the writings of St. Paul the gentiles are generally denoted as Greeks. The court of the gentiles about the temple was the outer space, marked off by a wall or balustrade breast high, within which strangers were forbidden to enter, though they might come as far as the barrier to present their offerings. This explains the meaning of Paul, when he speaks of "the middle wall of partition" between Jews and gentiles as being broken down by the gospel.

GENTILESCHI, ORAZIO, whose family name was Lomi, an Italian painter, born in Pisa in 1568, died in London in 1647. At the invitation of Charles I. he took up his residence at the court of England, and was employed to decorate the palace at Greenwich and other public buildings. He was held in such estimation that Vandyke included him in his series of portraits of 100 illustrious men.

GENTLEMAN, an English title, having its equivalent in all the Romance languages, and applied, according to Selden, to one "that either from the blood of his ancestors, or the favour of his sovereign, or of those that have the virtue of sovereignty in them, or from his own virtue, employment, or otherwise, according to the customs of honour in his country, is ennobled, made gentile, or so raised to an eminence above the multitude, that by those laws and customs he be truly *nobilis*, or noble,

whether he have any title, or not, fixed besides on him." This definition would include noblemen, and all above yeomen. In another old English law book, a gentleman is defined to be "one who, without any title, bears a coat of arms, or whose ancestors have been freemen;" and according to another: "Whosoever studieth the laws of the realm, who studieth in the universities, who professeth the liberal sciences, and (to be short) who can live idly and without manual labor, and well bear the port, charge, and countenance of a gentleman, he shall be called master and taken for a gentleman." The title is now one of courtesy, and is given in England to any man above the rank of a common tradesman, whose manners and deportment indicate a degree of refinement and intelligence, and whose conduct is regulated by a true principle of honor. The title is so generally and vaguely used in the United States that no exact definition can be given of its meaning, which varies in different classes of society. The laws recognize no such distinction among men, though in legal documents, such as title deeds, a man who has no definite occupation is often styled a gentleman.

GENTOO (Port. *gentio*, gentile), a term used by old English writers to designate the natives of India. It is now obsolete, having been long superseded in popular use by Hindoo.

GENTRY, a N. W. co. of Mo., bordering on Iowa, intersected by Grand river, and drained by its E. and W. forks; area, 770 sq. m.; pop. in 1856, 8,781, of whom 69 were slaves. In 1850 it produced 180,528 bushels of Indian corn, 17,045 of wheat, 23,864 of oats, and 11,582 lbs. of wool. Named in honor of Col. Richard Gentry, who fell at the battle of Okeechobee, Florida, in 1837. Capital, Gentry Court House.

GENTZ, FRIEDRICH VON, a German diplomatist and publicist, born in Breslau in 1764, died June 9, 1832. He studied at Berlin and Königsberg, and was secretary to the directory of finances at Berlin when the French revolution broke out, of which he was from the beginning an ardent opponent. In 1792 he translated into German Burke's famous pamphlet on this subject, adding many violent notes to it. In 1802 he passed into the service of Austria, and after being sent to England to negotiate an alliance, drew up the Austrian manifesto of 1805. After the peace of Presburg he returned to Berlin, and after the disaster at Jena retired again to Vienna, where he composed the eloquent Austrian manifesto of 1809. He took part in the conferences of Vienna, and assisted in drawing up the treaty of the holy alliance. He wrote upon the morality of revolutions, the declaration of the rights of men, the principles of the French revolution, and the finances and national wealth of Great Britain. In literature he sympathized with the romantic school of Germany, and in politics defended absolutism.

GENUS, a closely allied group of animals or plants, characterized by ultimate structural

peculiarities. The higher relations of animals and plants, from branches to families, have been treated in the article **FAMILY**. Great confusion prevails among describers in the formation of genera, from their considering form and complication of structure as generic characters, whereas the former is characteristic of families, and the latter of orders; hence generic, family, and ordinal characters are mixed up in the determinations of almost all naturalists from Linnaeus to the present time, and genera have been unnecessarily and absurdly multiplied. Genera are subdivisions of families, and species are subdivisions of genera; the former, as has been stated, are limited by ultimate structural peculiarities, while the latter bear a closer relation to each other and to their special localities, their existence being also confined within a definite period. Generic peculiarities extend to the most minute details of structure of teeth, hair, scales, cerebral convolutions, distribution of vessels, arrangement of intestinal folds and appendages, and microscopic anatomy of the organs; so complete is this identity of structure that (in the words of Agassiz, "Essay on Classification," part i. chap. 1) if an animal were "submitted to the investigation of a skilful anatomist, after having been mutilated to such an extent that none of its specific characters could be recognized, yet not only its class, or its order, or its family, but even its genus, could be identified as precisely as if it were perfectly well preserved in all its parts." Every species of the genus *vulpes* (fox), for example, has the same dental formula, toes and claws, and other generic characters, whether arctic, tropic, or temperate, American, European, or Asiatic, in its habitat. Genera may or may not resemble each other in form; they usually have a wide geographical range, and, like the higher as well as lower relations among animals, are entirely unmodified in their characters by physical and external agencies. In the sauroid family of the ganoid fishes, for instance, we have the genera *lepidosteus* (gar pike) and *polypterus*; in the former, among the generic characters, are the narrow lengthened jaws, branchiostegous membrane with 3 rays, single dorsal fin near the tail, 1st ray of all the fins covered with imbricated serrated scales, caudal fin attached to the under side of the vertebral column, half gill on the gill cover, swimming bladder entirely cellular in 2 lateral halves communicating with the upper wall of the oesophagus, a slight spiral intestinal valve, and many pancreatic cæca; in the latter the head is oval and rounded anteriorly, 2 cirri above the mouth, 2 spiracles on the sides of the head, a very complicated nasal apparatus, branchiostegous membrane with a single flat ray, caudal fin rounded, numerous dorsal fins, no gill or gill cover, swimming bladder sacciform, not cellular, with fine internal longitudinal folds, and opening on the under side of the oesophagus, a well marked spiral valve, and a single pancreatic cæcum. The generic distinctions of the *testudinata*, or tor-

toises, both land and marine, founded principally on the characters of the skull, jaws, skin, and feet (see Agassiz, "Natural History of the United States," vol. i.), give an admirable idea of what constitutes a genus, as distinguished from families and orders.

GEOCENTRIC (Gr. *γη*, earth, and *κεντρον*, centre), having the earth as its centre or point of reference; a term used chiefly in astronomy.

GEODE, a hollow shell of stone, commonly of quartz, found in various rocks, and usually lined with crystals pointing toward the centre. These crystals are for the most part of quartz, often amethystine. Among the amygdaloids of the trap are found geodes of agate and chalcedony, the shell made up of concentric layers of these variously colored silicious matters. Beside quartz crystals, others of calcareous spar, analcime, &c., are found in the cavities of geodes. Some of the most remarkable specimens of this kind in the quartz geodes are found in low stages of water loose in the rapids of the upper Mississippi river. Externally they are rough and unsightly, of light brown color, and of all sizes up to 12 or 15 inches in diameter; when broken they present beautiful groups of quartz crystals. Water is sometimes found in the geodes holding the siliceous solution, and making with it a milky looking mixture. As the water evaporates the siliceous has been known to suddenly form into delicate crystals. Such geodes were at one time abundantly found on Briar creek in Scriven or Burke co., Ga., in a rock composed of hornstone and jasper; the milky fluid contained in them was used by the inhabitants as a paint or whitewash. ("American Journal of Science," vol. viii. p. 286.)

GEODESY (Gr. *γη*, earth, and *μετρον*, to divide), the science and art of laying out divisions of the earth's surface upon a large scale. It differs from ordinary surveying in its measurements being constantly referred to the spherical surface upon which they are made, and reduced to the same horizontal level. Corrections also are made for horizontal parallax in computing the value of instrumental observations, and the calculus of probabilities is applied to resolve their differences. Its object may even be the determination of the spherical curvature of portions of the surface, which is accomplished by the aid of extended series of astronomical observations made in connection with the most exact measurements. The methods of conducting these operations and contending with the numerous causes of error, incident to the imperfection and comparative insignificance of the instruments and powers employed, are treated in the article on the U. S. COAST SURVEY, which is the most perfect as it is the latest example of large geodetical operations.

GEOFFREY OF MONMOUTH, an old English chronicler, born probably in Monmouth about 1100, died about 1154. He is supposed to have received his education in the Benedictine monastery near Monmouth, where he compiled his *Chronicon sive Historia Brittonum*, to which

he probably owed his promotion in 1152 to the see of St. Asaph. Geoffrey's chronicle professes to be a translation from an old Welsh manuscript which one Walter Calenius, an archdeacon of Oxford, discovered in Brittany, and which he requested him to render into Latin. That some part of the work is a translation there seems to be no doubt, as its main features agree with the history of Nennius, written 3 centuries previous; but so numerous are the legends and fables interwoven into it, and so extensive is the period it embraces—from Brut the great-grandson of Æneas to the death of Cadwallader or Ceadwalla, king of Wessex, in 688—that its historical value is very inconsiderable. If historians are inclined to doubt the veracity of Geoffrey, the readers of romance are indebted to him for having preserved and perhaps reconstructed the delightful legends of Arthur and his knights, the romantic fairy pageantry of which can be traced through so many centuries of English poetry. The work was originally divided into 8 books, to which Geoffrey added the book of Merlin's "Prophecies." The best recent editions are those of J. A. Giles (1842), and Bohn (1848), both of which are reprints from a translation by Aaron Thompson originally published in 1718.

GEOFFROY, JULIEN LOUIS, a French critic, born in Rennes in 1748, died in Paris, Jan. 26, 1814. A pupil of the Jesuits, he was first a tutor in the Montaigu college, then in a private family, and commenced his literary career with a tragedy never performed nor printed. In 1776 he was appointed professor of rhetoric in the college of Navarre at Paris, and soon left it to occupy the same chair in the Mazarin college. About the same time he became a contributor to the *Année littéraire*, a review founded in 1754 by Fréron, and he continued to write for it for 15 years. From 1781 he also published another literary periodical called *Journal de Monsieur*; and in 1790 he undertook, in conjunction with Montjoie and the brothers Royou, the publication of an ultra-monarchical daily paper, *L'ami du roi*, which was discontinued Aug. 10, 1792. In order to avoid the dangers incurred from his monarchical opinions, Geoffroy left Paris, and became a schoolmaster in some obscure village. He returned to the metropolis after the 18th Brumaire (1799), attempted to resuscitate the *Année littéraire*, and became attached to the *Journal des débats* as literary critic. Theatricals were his especial province; and his *feuilletons*, in which he displayed great scholarship and bitter sarcasm, enjoyed unparalleled success. His articles were collected and published in 1819-'20 under the title of *Cours de littérature dramatique*.

GEOFFROY SAINT HILAIRE, ÉTIENNE, a French zoologist, born in Étampes, April 15, 1772, died in Paris, June 19, 1844. He was first educated for an ecclesiastical life, but early evinced a taste for natural philosophy, and was encouraged by Haty and Daubenton to follow his inclination. He had already gained

some proficiency as a mineralogist when the revolution broke out. Having been incarcerated as a recusant priest, his pupil managed to procure his liberation, and at the peril of his life he rescued 12 other priests from prison, on the very eve of the massacre of Sept. 1793. A few months later he was appointed to a subordinate office in the *jardin des plantes*, and in 1798, on the reorganization of this establishment under the name of "Museum of Natural History," he was promoted to the professorship of zoology, and of course intrusted with the keeping of the collections. To this twofold task he devoted himself entirely; but while he succeeded as a lecturer, he accomplished wonders in his other functions. Through his unflinching zeal and exertions, the old specimens were put in order, new ones were procured from every part of the world, and finally the zoological collections, under his supervision, became the richest in the world. In 1795 he welcomed to Paris, and treated as a brother, George Cuvier, then entirely unknown to fame; both in concert pursued researches in comparative anatomy, and at that time each of them had but a faint conception of the opposite systems upon which they were to separate some 35 years later. In 1798 Geoffroy consented to be one of the scientific commission that accompanied Bonaparte to Egypt; remaining there until the surrender of Alexandria in 1801, he was one of the founders and most active members of the Egyptian institute, thoroughly explored the country, gathered valuable collections of natural specimens, and succeeded in bringing them to France; he threatened to burn them all rather than deliver them into the hands of the English, as the terms of capitulation required. The papers in which he described these specimens attracted general attention, and resulted in his election to the academy of sciences in 1807. The next year he went on a scientific mission to Portugal, and on his return he was appointed to the professorship of zoology in the faculty of science at Paris, which post he filled for years simultaneously with that at the museum. From 1812 to 1815 his scientific occupations were partly interrupted by sickness and political activity. He was a member of the chamber of deputies during the Hundred Days; but on the second restoration he returned to his wonted pursuits, and then commenced the unfolding of his philosophical system. He applied himself to demonstrating the principle of which Buffon and Goethe had had but a glimpse, the unity of organic composition among the various kinds of animals; and he founded what he called the "theory of analogues." The unity of composition, according to his idea, is the law of identity in the materials composing the organs of animals of different families, and which, although infinitely varying in shape, bulk, and use, are still the same in all, and discover a single plan; while the theory of analogues is the method through which the unity of composition is demonstrated. As to

the unequal sizes among the various creatures, and monstrosities in individuals, they are explained by the principle of arrest of development. These principles, at once bold and original, were in direct contradiction to those which Cuvier had adopted as the basis of his comparative anatomy; and this opposition, which had been silently going on for years, at last broke out openly, July, 1830, in the sittings of the academy of sciences. The contest between two illustrious champions, well armed with all the resources which science, experience, and talent could afford, caused a deep sensation throughout the scientific world of Europe; and in the estimation of Goethe, it was far more important to humanity than the political revolution that was going on at the same time. Notwithstanding the superiority of Cuvier as an orator and scientific expounder, the victory was left undecided, and many among the learned sided with Geoffroy, whom the great German poet hailed as an apostle of the true synthetic doctrine. Whatever may have been his faults, he is incontrovertibly, after his opponent and friend Cuvier, one of the most important contributors to the advancement of the science and philosophy of natural history. His views contain much of the transcendental element of the German physio-philosophers, and, if carried to their legitimate conclusions, lead to doctrines directly opposed to the prevalent philosophy of final causes; his ideas will be further elaborated in the article PHILOSOPHICAL ANATOMY. Among his numerous works and papers, which embrace nearly all branches of zoology, we refer specially to the following: *Philosophie anatomique* (3 vols. 8vo., 1818-'22), which contains the exposition of his doctrine; *Principes de la philosophie zoologique* (8vo., 1830), which gives a synopsis of his discussions with Cuvier; *Études progressives d'un naturaliste* (4to., 1835); *Notions de philosophie naturelle* (8vo., 1838); *Fragments biographiques* (8vo., 1838); *Histoire naturelle des mammifères*, in conjunction with Frédéric Cuvier (fol., 1820-'42). He also contributed to several great publications, and especially to the description of Egypt by the scientific commission of which he was a member. It was not till 1840 that he gave up active life on account of blindness; a few months later he had a stroke of paralysis; but he withstood his last sufferings with admirable equanimity. His eulogy was delivered by M. Flourens in 1852 at the academy of sciences; an excellent biography had been previously published by his son under the title *Vie, travaux et doctrine scientifique d'É. Geoffroy Saint-Hilaire* (Paris, 1848).—LARDER, a French zoologist, son of the preceding, born in Paris, Dec. 16, 1805. Under the direction of his father he early devoted himself to natural philosophy, became assistant naturalist at the museum when only 19 years old, and in 1830 delivered zoological lectures in that institution as his father's substitute. Three years later he was elected to the academy of sciences. He was then

publishing a great work in which he enlarged upon a branch of the natural system outlined by his father; this was his *Histoire générale et particulière des anomalies de l'organisation des l'homme et les animaux, ou traité de tératologie* (3 vols. 8vo., with an atlas, 1832-7). On its completion he was appointed assistant lecturer to his father at the faculty of sciences, afterward filled some important offices in the university, and finally in 1850 resigned the post of general inspector to resume the chair of zoology, to which he was then formally appointed. He has since devoted his leisure to publishing his *Histoire naturelle générale des règnes organiques*, which was commenced in 1852, and is still in progress, and is to be completed in 5 vols. 4to. He has also paid much attention to the domestication of foreign animals in France, as appears from his treatise, *Domestication et naturalisation des animaux utiles* (Paris, 1854), and has advocated the use of horse flesh as food in his *Lettres sur les substances alimentaires, et particulièrement sur la viande de cheval* (Paris, 1856).

GEOGNOSY (Gr. *γη*, the earth, and *γνῶσις*, knowledge), the science of the structure of the earth; a term introduced by Werner, for which the synonymous term geology has since been substituted. Dr. Whewell suggests that in adopting the name geognosy, the knowledge of the earth, instead of geology, the Wernerians appear to have intended to select descriptive geology for their peculiar field.

GEOGRAPHY (Gr. *γη*, the earth, and *γραφειν*, to write), the description of the earth. The science of geography comprises 3 principal divisions: mathematical geography, physical geography, and political geography. Mathematical geography treats of the figure, magnitude, and motion of the earth, of the construction of globes, and the solution of problems; of the mode of determining the position of places on the earth's surface, and of representing any portion of that surface on maps or charts. Most of these topics belong as much to astronomy as to geography. (See **ASTRONOMY**, and **EARTH**.) Physical geography treats of the earth and its features of land, water, and air, its animal and vegetable inhabitants, and under reference to national or political divisions. (See **PHYSICAL GEOGRAPHY**.) Political geography describes the countries and nations of the earth as they are politically divided, and deals with mankind in their social aspect and organization. The details of this branch of the science will be found under the names of the various countries, cities, and towns of the globe.—Among the ancients, the Phœnicians were the first who made any great progress in extending the bounds of geographical knowledge. They seem to have explored all the coast of the Mediterranean, and at an early period to have passed the strait of Gibraltar, and visited to some extent the Atlantic shores of Europe and Africa, extending their voyages northward as far as Britain and southward to the tropic of Capricorn. Their neighbors, the Hebrews, probably acquired from them some knowledge of distant lands. In

the Scriptures the remotest regions mentioned are, to the N., Gomer (Gen. x.), by which was probably meant the Kimmeri of Herodotus, and Kir, the Caucasian region of the Kur; to the E., India (Esther i. 1), and very probably China, called the distant "land of Sinim" (Isaiah xlix. 12); to the S., Cuah (Ethiopia), Ludim or Lubim (Libya), Dedan, Sheba, and Ophir, concerning whose situation many conjectures have been made, the most probable of which seems to be that it was a place in southern Asia. To the W., the extreme land was Tarahish, which was probably Tartessus in Spain, though some critics suppose it to have been Carthage. The first attempt to enlarge the bounds of geographical knowledge by an exploring expedition was made by Necho, king of Egypt, about 604 B. C. He sent down the Red sea into the Indian ocean a fleet manned by Phœnicians, which in the third year, after circumnavigating Africa, reached the pillars of Hercules or strait of Gibraltar, and returned to Egypt by the Mediterranean. Herodotus, who relates this extraordinary voyage, expresses his disbelief of the circumstance which to modern science affords the strongest proof that it really took place. The Phœnicians on their return asserted that during a part of the voyage the sun was in the north. This statement, which shows conclusively that they must have sailed to the south of the equator, Herodotus, naturally enough, wholly discredited. The geographical knowledge of the ancients was greatly enlarged by the Carthaginians, whose extended commerce led necessarily to long voyages, but the only authentic account of any of their maritime expeditions which has reached us is that of Hanno, the time of which is uncertain, but is plausibly conjectured to have been in the 5th century B. C. With a fleet of 90 vessels he passed the strait of Gibraltar, and sailed down the coast of Africa, as some writers suppose, to the gulf of Benin, while according to others he proceeded no further than the river Nun. About 320 B. C., Pytheas, a seaman of Massilia, the modern Marseilles, sailed out into the Atlantic, coasted the shores of Spain and Gaul, visited Britain, and passing onward, discovered an island, which from that time was famous among the ancients as *Ultima Thule*. It has been conjectured that this was Iceland, but nothing certain is known about it. The Indian expedition of Alexander the Great, 320 B. C., greatly enlarged the ancient knowledge of India. He penetrated to the Hyphasis, the modern Sutlej, the most eastern and most important of the 5 rivers which flow through the Punjab. The ambassadors of Seleucus, one of his successors, reached the Ganges and visited the city of Palimbothra, which was probably on the site of the modern Allahabad. Beyond this the Greeks seem to have known little or nothing of eastern Asia. The first systematic attempt at scientific geography was made by Eratosthenes, who lived between 276 and 196 B. C., and was an eminent scholar at Alexandria in the reign of Ptolemy III. The globular form

of the earth was at this time known to the scientific schools of Alexandria, and the system of Eratosthenes was based upon its recognition, though he disregarded the great primal features of modern geographical science, the equator, the poles, and the tropics. The base line of his geography was a parallel drawn from W. to E. through all the places where it was supposed that the longest day was 14½ hours. It stretched from Cape St. Vincent in Spain eastward through Rhodes, Asia Minor, Persia, and India, till it terminated at the city of Thinae, which was supposed to be on the shores of the eastern ocean at the utmost extremity of the earth. The distance from one extremity of this line to the other, according to Eratosthenes, was about 70,000 stadia, or 9,000 miles. At right angles to this parallel Eratosthenes traced a meridian which passed through Rhodes and Alexandria southward through Syene and Meroë, till it reached what was supposed to be the uninhabitable region, the northern bounds of which were fixed at 12 degrees from the equator. Thule was regarded by Eratosthenes as the extreme northern end of the earth, and the distance from there to the habitable limit toward the equator was computed at 88,000 stadia, or nearly 5,000 miles. Beyond these limits of 9,000 miles in length and 5,000 miles in breadth it was commonly supposed that nothing existed but an impassable ocean, though Eratosthenes cautiously conjectures that there might exist in it continents and islands which could be reached by sailing westward. Hipparchus, a Bithynian who lived at Rhodes (160-145 B. C.), carried still further the system adopted by Eratosthenes, and subjected the whole science of geography to astronomical principles. He made numerous observations of latitude in addition to the few previously existing, and pointed out the mode in which longitudes might be ascertained by observing the eclipses of the sun and moon. But Hipparchus was greatly in advance of his age, and his discoveries were neither appreciated nor applied to any practical use till long after his time. Somewhat more than a century after Hipparchus, Strabo, a Greek of Pontus and a great traveler, wrote a geography which embodies all that was known of the science at the beginning of the Christian era. The countries immediately around the Mediterranean were known with tolerable accuracy; but the Atlantic shores of Europe were very erroneously comprehended, while of the northern and eastern portions only the vaguest ideas were entertained. Nothing whatever was positively known of Scandinavia, Russia, or of northern Germany. The extent of Europe to the E. and N. E. was greatly exaggerated, while that of Asia was proportionally underrated. Nothing was known of Siberia, Tartary, China, Japan, or the great Asiatic archipelago. The Ganges was thought to have throughout an easterly course, and to flow into the eastern ocean. The Caspian was supposed to be the limit of the earth to the N., and to be

connected with the eastern ocean by a sea occupying the space now known to be covered by Siberia and Tartary. Of Africa only the northern part was known, S. of which was thought to be an uninhabited and uninhabitable torrid zone. The belief in the probability of circumnavigating Africa, which had existed in previous ages, was rejected by Strabo, though he held to the theory of an encircling ocean. A still more famous geographer than Strabo was Ptolemy, who lived at Alexandria about the middle of the 2d century after Christ. At this period the Roman empire had reached its greatest extent, and all its provinces had been surveyed and were well known. Large advances had been made in the knowledge of the countries outside of the empire. The notion of a circumambient ocean had been given up, and an indefinite expanse of *terra incognita* substituted as the supposed boundary of the world. Africa, however, was represented as stretching indefinitely S., and it was even carried round to join the E. of Asia, so that the Indian ocean was enclosed like the Mediterranean. In Europe, Spain and Gaul were for the first time correctly delineated, together with the southern part of Britain. The outline of Scotland and the relative position of Ireland are very incorrectly given. Thule is laid down as an island upward of 100 m. in length. From its position it is probable that some part of Norway was meant. Northern Germany and the southern line of the Baltic coast were tolerably well known, as was also some portion of Russia in the neighborhood of the Baltic and the southern part of Russia in Europe. In Asia, great regions had become known sufficiently to make it certain that they were inhabited by nomade tribes called Scythians, while from the far east some vague report of China and of the regions now known as Chin-India had reached the geographer. From the time of Ptolemy till the revival of letters in Europe little progress was made in geographical knowledge. In the 18th century missions were sent by the popes into remote parts of Asia. Father John de Plano Carpini, with some Franciscan monks, was sent in 1246 by Innocent IV. to Kayuk Khan, the Tartar emperor, and penetrated as far as Thibet. In 1253 Rubruquis, another Franciscan, was sent by Louis IX. of France in search of Prester John, and penetrated further into Asia than any European had ever before done. But the greatest discoveries in this quarter were made by the celebrated Marco Polo, a Venetian noble, who in 1265 set out with his father and uncle on a journey to the court of Kublai Khan, the Tartar conqueror of China. After travelling for more than 8 years they reached Yeh-king, near where Pe-king now stands. Marco Polo resided 17 years in the East, and on his return gave an account of his travels, which first made known to Europe the existence of Japan and of many of the East Indian islands and countries. In the 15th century the spirit of enterprise and of geographical exploration was strongly aroused in Europe. Portugal

took the lead, and made great and systematic efforts to explore the unknown countries on the W. coast of Africa. In the year 1412 Cape Non was doubled, and soon afterward the islands of Porto Santo and Madeira were discovered. In 1484 Benin and Congo were discovered, and the coast explored for 1,500 miles S. of the equator. Finally in 1486 the cape of Good Hope was reached, and 11 years later doubled by Vasco da Gama. But the greatest of all geographical discoveries was that of the new world by Christopher Columbus in 1492. From this time forward the progress of geographical exploration was exceedingly rapid. Within 30 years from the date of the first voyage of Columbus the whole E. coast of America from Greenland to Cape Horn had been explored, and Spanish keels were floating on the Pacific ocean. In 1520 Magellan passed the straits which bear his name, and his vessel, crossing the Pacific and Indian oceans, returned to Europe by way of the cape of Good Hope, having for the first time circumnavigated the globe. The W. coast of America, with the exception of that portion N. of the bay of San Francisco, was explored before the middle of the 16th century, while considerable progress was made by the Spaniards in acquiring a knowledge of the interior of South America. At the same time discovery in the East advanced with rapid strides. Within 20 years from the time of Gama's arrival in India, the coasts of E. Africa, Arabia, Persia, Hindostan, and Further India had been explored, and many of the islands of the great archipelago discovered. In the 16th and 17th centuries the progress of astronomical science led to a general revision of Ptolemy's tables of latitude and longitude, which had for ages been received with implicit confidence, but which more accurate observations now proved to be generally erroneous. In the 18th century many learned and laborious writers, among whom M. d'Anville may be particularly mentioned, applied themselves to the rectification of the whole system of ancient geography, and to the identification of ancient with modern countries, cities, rivers, mountains, and other features. The desire to discover a shorter route to India than those by Cape Horn and the cape of Good Hope led the English and the Dutch in the 16th century to make daring and persevering efforts to effect a N. E. and a N. W. passage. For a long time the opinion prevailed that the northern extremity of America terminated, like the southern, in a point or cape, by sailing round which the mariner could enter the Pacific ocean and make his way to India. The expeditions of Sir Hugh Willoughby and Richard Chancellor in 1553, of Frobisher in 1576-'8, of Davis in 1585-'8, of Barentz in 1594-'6, in search of this northern route, greatly enlarged our knowledge of the arctic regions, and especially of the N. E. part of North America. So too in the succeeding century a similar result followed from the voyages of Henry Hudson, in 1607-'11, and of William Baffin in 1616. It was not till the

latter part of the 18th century, however, that the great breadth of the upper part of North America became fully known from the investigations of Capt. Cook in his voyages to the Pacific. The determination of the distance from Behring's straits to the E. coast of North America dispelled for a time all expectation of a N. W. passage. It was supposed that the continent stretched in one unbroken mass to the pole. The discoveries of Hearne in 1771 and of Mackenzie in 1789, by showing that an ocean bounded America on the north, dispelled these ideas, and in 1818 the attempt to effect the N. W. passage was revived by an expedition commanded by Capt. Ross. This was the beginning of a series of English and American expeditions to the arctic regions, which have within a few years greatly advanced our knowledge of that part of the world, though without attaining the object for which they were commenced. (See ARCTIC DISCOVERY.) Early in the 17th century the Dutch, while seeking for a southern continent whose existence was supposed necessary to balance the northern continent, discovered Australia, which they called New Holland, and explored a considerable portion of its coasts. In 1642 Tasman discovered Van Diemen's Land, or Tasmania, as it is now called. Soon afterward he discovered New Zealand and several of the Polynesian groups. His explorations proved that New Holland was an island, and not a part of the southern continent. The famous Capt. Cook in his voyages, 1768-'79, made strenuous efforts without success to discover the southern continent. He however added largely to geographical knowledge by his survey of the Pacific ocean and its innumerable islands. An expedition sent out by the United States in 1838, under command of Lieut. Wilkes, succeeded in 1840 in discovering a continent within the antarctic circle, portions of which were also seen in the same year by the French and English navigators Dumont d'Urville and Sir James Ross. (See ANTARCTIC DISCOVERY.) Our acquaintance with the interior of Asia has been greatly advanced within the last two centuries by a multitude of travellers, prominent among whom have been the Jesuit missionaries, so that at the present day our general knowledge of the continent of Asia is tolerably complete. No great *terra incognita* remains, though fuller and more precise information about the vast regions known as Tartary is much to be desired. The travels of Humboldt, of Lewis and Clark, and of Fremont have perfected our acquaintance with the interior of the American continent. The interiors of Australia and of Africa are however still only partially known. Much has been done for the exploration of the former by Sturt, Eyre, and Leichhardt, while in Africa a host of travellers have struggled for a century past to penetrate the mystery which from the remotest period has enveloped that great division of the globe. Foremost among the African explorers we may name James Bruce, Mungo Park, Major Denham, Lieut. Clapperton, Richard Lander, Cap-

tain Burton, Dr. Livingstone, and Dr. Barth. Great additions have been made to our knowledge of the countries on the upper Nile by expeditions recently sent by the pasha of Egypt, which have penetrated far beyond the region so long assigned on our maps to the mountains of the Moon. These expeditions and the researches of Barth, Burton, Livingstone, and the missionaries Rebmann and Krapf, have left in obscurity only a portion of that part of Africa which lies between lat. 10° N. and 10° S. The veil that still hangs over that will doubtless soon be dispelled, so that of the whole earth nothing will remain wholly unknown to the science and the curiosity of civilized man except the frozen regions round the poles. The remarkable progress of geographical discovery within the last half century has been thus summed up by Mr. Bayard Taylor: "Within that time all the principal features of the geography of our own vast interior regions have been accurately determined; the great fields of central Asia have been traversed in various directions from Bokhara and the Oxus to the Chinese wall; the half-known river systems of South America have been explored and surveyed; the icy continent around the southern pole has been discovered; the N. W. passage, the *ignis fatuus* of nearly two centuries, is at last found; the Dead sea is stripped of its fabulous terrors; the course of the Niger is no longer a myth, and the sublime secret of the Nile is almost wrested from his keeping. The mountains of the Moon, sought for through 2,000 years, have been beheld by a Caucasian eye; an English steamer has ascended the Chadda to the frontiers of the great kingdom of Bornou; Eyre, Leichhardt, and Sturt have penetrated the wilderness of Australia; the Russians have explored the frozen shores of northern Siberia, and descended from Irkutsk to the mouth of the Amoor; the antiquated walls of Chinese prejudice have been cracked, and are fast tumbling down; and the canvas screens which surrounded Japan have been cut by the sharp edge of American enterprise. Such are the principal features in the progress of modern discovery. What half century since the form of the earth and the boundaries of its land and water were known, can exhibit such a list of achievements?"—The literature of geography has within a few years undergone a marked change. Instead of the formal, regular descriptions of the earth and its inhabitants, which were once in vogue, gazetteers and geographical dictionaries are now popular. (See GAZETTEER.) The progress of geography has been much aided during this century by the efforts of zealous geographical societies, among which those of England and France are particularly distinguished. Their transactions, issued periodically, contain a vast and constantly increasing mass of information. Among the best works on geography are *Précis de la géographie universelle, ou description de toutes les parties du monde sur un plan nouveau, d'après les grandes divisions du globe*, by Malte-

Brun (Paris, 1810-'37), of which a translation into English was made by the late James G. Percival, 1827-'32, under the title of "Universal Geography" (6 vols. 8vo., Philadelphia, 1827-'32); "An Encyclopædia of Geography," by Hugh Murray (1 vol., London, 1835; 2 vols., Philadelphia, 1836; new edition, 1857); Karl Ritter's great work, *Die Erdkunde im Verhältnisse zur Natur und Geschichte des Menschen*, and many other works by the same author and by his followers, Von Rougemont, Von Roen, Berghaus, Volger, Merleker, Meinicke (*Lehrbuch der Geographie*, 1857), and Klöden (*Handbuch der Erdkunde*, 1858). Smith's "Dictionary of Greek and Roman Geography" (2 vols. 8vo., London, 1854-'7) contains a full and methodical compendium of all that remains of the geographical knowledge of the ancients.

GEOLOGY (Gr. *γῆ*, the earth, and *λογος*, discourse), the science which treats of the structure of the earth and the methods by which its materials have been arranged. Its study embraces all matters that form the portion of the earth within the reach of man's observation; it brings them together into appropriate groups, and investigates the changes through which they have passed. It thus divides itself into 2 departments, descriptive geology and physical geology, the latter treating especially of the causes of production, or of geological dynamics. In this department a close connection and mutual dependence are perceived at the outset between this and the other physical sciences. Some of the laws which affect the distribution and condition of masses upon the surface of the earth are more perfectly comprehended in the grander scale of their action, as they influence the movements and condition of the heavenly bodies; others are to be explained only by reference to meteorological agencies, as the rains, frost, winds, &c.; others by the mechanical forces exerted by running water; and a large class depend for their position on the chemical operations that are everywhere going on, changing the conditions of matter, and even in the still depths of the sea and the apparently unchangeable strata deeply buried in the earth, producing grander results than those displayed by the noisy eruptions of the volcano. So closely are all departments of nature linked together, that even the habits of insignificant insects, as already explained under CORAL, must be studied to account for the formation of geological structures of vast extent; and under ALLUVIUM it is shown that the infusoria, the minutest organic forms that we can recognize, make up by their shelly remains the substance of extensive deposits. The vegetable kingdom, too, has contributed an important share to the materials that compose the strata of the earth; and botany is thus enlisted to elucidate geological phenomena, while its own sphere is enlarged by the strange flora of past epochs faithfully preserved in geological herbaria. Many of the rocks are found filled with shells, and containing relics of various other animal forms; whence

conchology and zoology become aids to geological investigations as requisite as botany, and are themselves similarly advanced by the new field thus opened to them. Comparative anatomy also has been so extended by the demands of geology for an explanation of the true character of the bones and other animal remains preserved in the rocks, and differing strangely from all belonging to known living forms, that this may be regarded almost as a new science.—The changes that have taken place in the inorganic and organic world introduce in their study considerations of time and progress, and the science is found to partake largely of the historical character. It abounds with records of past events, and the geologist, as Ouvier remarked, is an antiquary of a new order. Its historical element is regarded by Lyell as so prominent that he defines geology simply as “the science which investigates the successive changes that have taken place in the organic and inorganic kingdoms of nature.”—In the present article little more will be attempted than to present a general sketch of the history and progress of geological science, a reference to some principal objects of its pursuits, and the systems of classifying the groups of rock generally adopted. The history of the science as developed in Europe is minutely traced in the familiar work of Lyell, “*Principles of Geology*,” in which the whole subject may also be most advantageously studied; while for special details reference may be made to the names of the formations and of the minerals, metals, &c., in their alphabetical arrangement in this cyclopædia. (See also MINERALOGY, and PALÆONTOLOGY.)—From the earliest times the structure of the earth has been an object of interest to man, not merely on account of the useful materials he obtained from its rocky formations, but also for the curiosity awakened by the strange objects it presented to his notice. The south and west of Asia and much of the country bordering the Mediterranean were particularly favorable for directing attention to geological phenomena. Earthquakes were of frequent occurrence, changing the relative position of sea and land; volcanoes were seen in operation, adding layers of molten rock to those of sand and mud filled with the shells of the Mediterranean; the strata in the hills abounded in evidences of similar collections of vestiges of marine life far removed from access of the sea, and yet unchanged during the period of human observation and tradition; the Ganges and the Nile pouring forth their vast sedimentary accumulations were plainly building up the deltas at their mouths, and the broad valleys reaching far up their course were unmistakable productions of the same series of operations in remote periods of time. These phenomena could not escape the attention of the philosophers among the ancient Egyptians and Indian races; and their influence is perceived in the strange mixtures of correct observations and extravagant conceits which make up their cosmogonies or universal theories of the creation. In the first

chapter of the ordinances of Manu alternating periods of destruction and of renovation are distinctly recognized, extending in eternal succession throughout the whole assemblage of locomotive and immovable creatures, each period comprehending a duration of many thousand ages. The Greek schools of philosophy recognized these phenomena, which were clearly enunciated by Ovid in presenting the doctrines of Pythagoras. Remarkably free from extravagant statements, they were applied to prove a system of perpetual change slowly modifying the surface of the earth. Aristotle recognized the interchanges constantly taking place between land and sea by the action of running water and of earthquakes, and remarked how little man can perceive in the short span of his life of operations extending through the eternity of time. Strabo distinctly applied the rising up of lands, not merely of small tracts, but of continents also, by earthquake convulsions, to account for the perplexing phenomenon of beds of marine shells contained in the interior of hills far distant from the sea. Arabian philosophers of the 10th century are cited who entertained similar views of the changes going on and their causes; and in an Arabian manuscript of the 18th century, preserved in the royal library at Paris, the changes that may occur in successive periods of 500 years are happily presented in the beautiful narrative of the mythical traveller Kidhiz.—The Italian philosophers in the early part of the 16th century were the first to engage in systematic investigations concerning the true nature of fossil shells. Their abundance in the strata of the sub-Apennine range could not fail to arrest attention and excite inquiries, now the more perplexing from the limited time allowed in popular belief to the past duration of the earth, and from the general persuasion that no great catastrophe except the Noachian deluge could have occurred to modify its surface. Various fanciful explanations were therefore adopted in the spirit of the scholastic disputations, and for 3 centuries argumentations were sustained with much spirit on the questions: first, whether fossil remains had ever belonged to living creatures; and secondly, admitting this, whether all the phenomena could not be explained by the deluge of Noah. Among those distinguished for the soundness of their views in the commencement of this controversy are Leonardo da Vinci, the celebrated painter, who died in 1519, and Fracastoro, whose attention was engaged by the multitude of curious petrifications which were brought to light in 1517 in the mountains of Verona in quarrying materials for repairing the city. He exposed the absurdities of the theories which referred the petrifications to a certain plastic force in nature that could fashion stones into organic forms, and showed the inadequacy of the traditional deluge to collect marine fossils that form solid strata of the earth. About this time collections of these curiosities were made for public museums and

private cabinets; they were deposited in the museum of the Vatican at Rome, and that of Canceolarius at Verona became famous for them. Descriptive catalogues of these collections were published; and as early as 1565 appeared one of the collection of John Keutman in Gessner's work *De Rerum Fossilium, Lapidum, et Gemmarum Figuris*. In 1580 Palissy was the first who dared assert in Paris that fossil remains of testacea and fishes had once belonged to marine animals. The truth, however, made but slow progress in the face of the established prejudices of the times. In 1669 Steno, professor of anatomy at Padua, published his work *De Solido intra Solidum naturaliter Contento*, in which he proved the identity of the fossil teeth found in Tuscany with those of living sharks, and the close similarity of the fossil testacea to living species; he traced their progressive change from unaltered shells to solid petrifications, and recognized the distinction between formations deposited by salt and by fresh water, and that some were of an earlier period than the introduction of plants and animals upon the earth. But neither he nor Scilla, the Sicilian painter, who in his Latin treatise on the fossils of Calabria, published in 1670, and illustrated by good engravings, ably maintained the organic nature of fossil shells, ventured to refer their occurrence in the strata to any other cause than the Mosaic deluge. Leibnitz, the great mathematician, in his *Protogæa*, published in 1680, first proposed the theory of the earth having originally been a burning luminous mass, which since its creation has been cooling down, and as it cooled received the condensed vapors which now compose its crust. In one stage of its formation he believed it was covered with a universal ocean. From these materials Leibnitz traced two classes of primitive formations, the one by refrigeration from igneous fusion, the other by concretion from aqueous solution. The first recognition of the arrangement of the earthy materials in strata, continuous over large areas, and resembling each other in different countries, appears to have been by Dr. Lister, who sent to the royal society in 1683 a proposal for maps of soils or minerals. He also believed that species had in past epochs become extinct. Dr. Robert Hooke prepared near the close of the 17th century a "Discourse on Earthquakes," which contains the most philosophical views of the time respecting the nature of fossils and the effects of earthquakes in raising up the bed of the sea. William Woodward was a distinguished observer of the geological formations of Great Britain, and perceived that the lines of outcrop of the strata were parallel with the ranges of the mountains. He formed about the year 1695 a collection of specimens which he systematically arranged and bequeathed to the university of Cambridge. For this he purchased the original specimens and drawings of fossil shells, teeth, and corals of Scilla, the Sicilian painter noticed above. But his geological system was cramped by the attempt to

make it conform to the received interpretation of the scriptural account of the creation and deluge. The Italian geologists Vallisneri in 1721, Moro in 1740, and Generelli in 1749, advanced the most philosophical views yet presented respecting the fossiliferous strata, and sustained them by original observations made by the first two throughout Italy and among the Alps. Moro endeavored to make the production of strata correspond in time to the account of the creation of the world in 6 days, and hence was compelled to refer them to volcanic ejections, which by floods, he imagined, were distributed over the surface of the earth and piled up in strata with marvellous celerity. Buffon advanced views respecting the formation and modification of mountains and valleys by the action of water in his "Natural History" (1749), a portion of which, contained in 14 propositions, he was required by the faculty of theology in Paris to renounce. This he did in his next work, accompanying the formal abandonment of what he had written contrary to the narration of Moses with a declaration of belief of all contained in the Scripture about the creation, both as to order of time and matter of fact.—Geology did not begin to assume the rank of an important science until its application to the practical purposes of mining was first pointed out in the last quarter of the 18th century by Werner, professor of mineralogy in the school of mines at Freiberg in Saxony. This distinguished man by his wonderful genius attracted pupils from distant countries, and sent them forth enthusiastic geologists and advocates of the views he had conceived from his imperfect observation of the geology of a small portion of Germany. He taught the systematic order of arrangement of the strata, adopting nearly the same divisions that had been proposed 50 years previously by Lehmann, a German miner. He explained their production as the result of precipitation from a common menstruum or "chaotic fluid," which he supposed had once covered the whole surface of the earth. As expounded by Jameson in 1808, the first precipitates from this ocean were chemical, and produced the crystalline rocks which lie at the base of all the others, and which he designated as the primitive class. They included the granitic rocks and those since called metamorphic, as gneiss, mica slate, clay slate, serpentine, &c. The 2d class comprised the rocks he calls transition, certain limestones, flinty slate, gypsum, graywacke, and trap, most of which are probably now included in the silurian formation. They were supposed to have been formed during the transition of the earth from its chaotic to its habitable state, and to have been partly chemical and partly mechanical in their origin, the latter worn down by the waves and currents. The 3d class contained the rocks denominated *Pleista*, because as observed in Germany they were disposed in horizontal or flat strata. In this was the coal formation, rock salt, chalk formation, old red

sandstone, numerous floetz limestones and floetz trap. They were supposed to have been formed while animals and vegetables existed in numbers, and to have been partly chemical and partly mechanical in their origin. They were not regarded as corresponding to the "secondary" of the French geologists, as this division comprehended some of Werner's transition class; still the division secondary is sometimes found among Werner's, as it was used by Lehmann. The 4th class contained the alluvial rocks, those produced on the land, as peat, sand and gravel, loam, bog iron ore, calc tuff, &c., being understood to comprise all above the chalk excepting the volcanic; the tertiary are thus entirely overlooked. The 5th class comprised the volcanic rocks, the pseudo-volcanic, and the true volcanic—the former being real or imaginary products of the combustion of coal and sulphurous matters, the latter of real volcanoes. These formations were supposed to be systematically arranged; the later formed either entirely covering the older, or, when these form a central mountain mass, encircling this, so that the "outgoings" of the strata (meaning their upper edges or lines of outcrop) form circles; those of the later formed groups being successively larger. The basin and trough-shaped deposits were also recognized, in which the outgoings of the newer strata became successively smaller. The strata, it was understood, were subject to local disturbances from portions sinking into subterranean cavities, and members might be wanting in some localities, but whenever present must be found in their proper position in relation to the rest. Basalt, which in Saxony and Hesse was seen capping the hills of stratified rocks, he inferred must be of the same series of precipitated formations, although many other geologists of Werner's time had fully established the analogy between this rock and modern lavas. The observations of Desmarest, especially in the district of extinct volcanoes in Auvergne, made in 1768, are referred to by Lyell as most clearly tracing the origin of the basalts to the craters of the volcanoes. A new controversy now arose, which for many years was waged with animosity and bitterness unprecedented in all other disputes of this class. Geologists throughout Europe were divided into the two classes of Neptunists, who advocated the production of the rocks by aqueous deposition alone, and Vulcanists, who attributed the origin of many of them to the action of fire. Hutton of Edinburgh was the acknowledged leader of the latter party. He had studied geology for himself in different parts of Scotland and England, and formed his own conclusions, which he ably sustained. He was the first to announce that geology had no concern with questions as to the origin of things, but that the true field of her investigations was limited to the observation of phenomena and the application of natural agencies to explain former changes. His friend Sir James Hall showed by actual experiment that the prismatic

structure of basalt might result in cooling from a state of igneous fusion; and Hutton himself rejoiced to find in the Grampian hills the granite branching out in veins, which extended from the main body through the contiguous micaceous slates and limestone, thus indicating its having been in a fused state, and this subsequent to the production of Werner's later formed rocks. This discovery soon led to questioning the existence of any primitive class of rocks, the origin of which lay beyond the reach of the present order of things; and the announcement made by Hutton: "In the economy of the world I can find no traces of a beginning, no prospect of an end," may well have startled men of science and shocked the religious public in the sensitive condition to which it had been brought by the infidel doctrines promulgated in the latter part of the last century, especially by men of letters of France. The Vulcanists came to be classed with the enemies of Scripture, the true object of investigation was lost sight of, and the controversy was continued with such animosity that the party names at last became terms of reproach, and many geologists avoided being involved in it. Workers in the field, however, were collecting new and valuable data that were to give to the science a more exact character. William Smith, a civil engineer, prepared in 1793 a tabular view of the strata near Bath, tracing out their continuity over extensive areas, and recognizing them by the fossils they contained. This method of identification and of arranging strata in their true positions he taught himself, and was the first to promulgate in England. With extraordinary perseverance he continued to prosecute his work alone, travelling on foot over all England, freely communicating his observations, and in 1815 he completed a geological map of the whole country. In France the importance of fossils as characteristic of formations was also beginning to be appreciated. De Lamarck and Defrance earnestly engaged in the study of fossil shells, and the former in 1802 reconstructed the system of conchology to introduce into it the new species collected by the latter in the strata underlying the city of Paris and quarried for the construction of its buildings. Six years previous to this Cuvier had established the different specific character of fossil and living elephants, which opened to him, as he stated, views entirely new respecting the theory of the earth, and determined him to devote himself to the researches which occupied the remainder of his life. In 1807 the geological society of London was established, with the professed object of encouraging the collection of data, multiplying and recording observations, with no reference to any "theories of the earth." Its active members completed the classification and description of the secondary formations of Great Britain, so well commenced by William Smith; while at the same time the tertiary formations were thoroughly investigated by Cuvier, Brongniart, and others in Paris. Thus

each country contributed to the advancement of geological science in the department connected with its most prominent formations—Germany in that of the lower stratified and metamorphic rocks, and especially in the mineralogical structure of these, while in Scotland the character of the granitic rocks had been more particularly elucidated, in England that of the secondary strata and their order of arrangement, and in France the tertiary.—The great principles gradually developed by these observations were: that the materials of the stratified rocks were sedimentary deposits that had slowly accumulated in the beds of ancient seas and lakes; that each stratum represented a certain period of time during which its materials were gathered, and that this period was characterized by its peculiar group of organized beings, the vestiges of which were buried and remained with it as records of the condition of this portion of the earth during this time. The piles of strata of various kinds indicated changes in the character of the deposits introduced, sandstones derived from sand alternating with shales derived from muddy and clayey deposits, and with calcareous strata, whose origin may have been in marl beds or coralline structures. The long succession of these strata, in connection with the evidences of their slow accumulation, observed in the undisturbed condition of the fossil remains they contained, bore witness to long periods of time occupied in the production of a single group of strata constituting but a minor division of one of the formations. The lapse of long periods of time was also indicated by the fossils becoming constantly more and more unlike existing species as found in beds of older date. The same localities, too, presented in their successive beds some that were filled with marine vestiges alone, corallines and sea shells clustered together as found in tropical oceans, and in layers of such thickness that ages must have passed while they were quietly accumulating; and above or below these were found other strata indicating that the surface was at another period covered with fresh water, the organic vestiges they contained being only of the character of those belonging to ponds and rivers; and yet again these localities became dry land, and were covered with the forests of tropical climes, and peopled with numerous strange species of animals, whose nearest living analogues are met with only in hot countries. Such changes as these also plainly marked slowly progressing revolutions, the period of which no one could compute by years. It was apparent that the sediments had collected as beds of sand and clay now collect in seas and lakes, and especially about the mouths of large rivers; but it was only in such as were evidently the product of the streams of the present day that the organic vestiges were recognized as belonging entirely to familiar species. In these alone were discovered any relics of man or any indications of his existence; and here they were not wanting, for fragments torn off

by the anchor from the newly formed sandstone floor of the sea brought up the works of his hands already entombed as fossils; and in the calcareous strata in process of formation and filled with recent species of shells has been found his skeleton. But with the first step back, even to the strata that form the soil of living peat beds, the bones of extinct gigantic mammalia introduce us to strange groups of animals, and no positive evidence of a satisfactory nature is afforded, either in the strata or in tradition, that man was their contemporary. Thus in the closest connection, geologically speaking, are we presented with the most striking examples of other great principles developed by geological research, viz., the extinction of old and the introduction of new species.—In consequence of the system of observation and close investigation now established, geology lost its highly speculative character, and rapid progress continued to be made in acquiring correct information of the arrangement of the strata of different countries. While the defects of Werner's classification were exposed, the general plan of it was seen to be founded in nature, and attention was directed to collecting everywhere the materials for filling out the vertical column of the rocks, as well as mapping them throughout their horizontal range. In every country some formations could be recognized, from which as a base a local classification might proceed to contiguous groups, and thus at last the whole be included in one system of classification. So the work of descriptive geology has ever since been going on, new discoveries continually adding to its completeness; and yet, as in all other investigations into the works of an infinite Author, with no promise of approaching the object in view, viz., the compilation of a perfect system, which in this case should present a full chart of the rocks from the lowest or oldest to the uppermost or most recent. Strata lying in juxtaposition in one region, when identified in another, are found to be separated by the interpolation of a new series; and again, in tracing out over broad areas a group of sedimentary strata, they are found gradually to assume new features, and even to undergo an entire change of chemical composition. So it would be if the vast submarine surface now receiving the sediments deposited by the Gulf stream were uplifted to form a new continent; the geologists of a future period, exploring its strata among the forests and beneath the soil of its north-eastern hills, would find them composed of the finest materials, such as may have been deposited from chemical solution, and differing materially from the coarse sediment distributed further to the south-west. The fossil remains too would be different, though all belonging to the same epoch of production, and included in the same geological group. Were the beds of the great northern lakes at the same time also exposed to observation, their sediment and vestiges would be found essentially different from those of the strata of marine

origin; and yet certain characteristics would unmistakably refer the production of them all to the same period in the world's history—a period subsequent to the introduction of man. From this explanation it follows that all stratified formations must be of limited area and thinning away at their edges, presenting the shape of lenticular sheets lapping upon each other.—In 1819 the geological society published a map of England greatly improved upon that of Smith by the labors of Mr. Greenough and his friends. About the same time Leopold von Buch prepared a similar map of a large part of Germany. A geological survey of France was ordered in 1822 by the French government, by which a complete geological map of France was finally constructed in 1841. M. Brongniart de Villiers, professor in the school of mines, was appointed to take charge of the work, and with him were associated Élie de Beaumont and Dufrenoy. The attention of these geologists was first given to an examination of the strata above the coal formation in England, where they had been most carefully studied, and particularly described by Conybeare and Phillips in their treatise on the "Geology of England and Wales" (1831). The secondary strata of Germany also were familiar to geologists; and both countries consequently furnished important points of reference for the arrangement of the groups of France. The chalk formation of Paris, the upper member of the secondary, served as the starting point, and proceeding from this they examined in detail the lower strata as they appeared successively emerging from beneath it, and identified them as they could with the corresponding groups of other countries. Such is the method ever since pursued, by which our knowledge of the strata which make up the outer crust of the earth has been systematically extended. The importance of the organic remains found in the rocks has been more and more appreciated, and the shells which constitute the chief portion of these have been most thoroughly studied; for while the different formations or groups of strata may contain numerous similar beds of limestone, sandstone, slate, and shales, not to be distinguished by their mineral characters, and which frequently cannot be traced to their meeting with other known formations by which their place or relative positions may be determined, the fossils show no such indiscriminate distribution; but each era was characterized by its peculiar group of animated beings, and if their arrangement is understood it follows that the position of any stratum in which the fossils are recognized must also be determined. A single species may in some cases be peculiar to one member of a geological formation, and serve wherever the fossil is found to identify the rock; but usually in different countries their identification by fossils is dependent upon characteristic genera and the order of succession of their principal groups. This branch of the subject will be more particularly treated in the article PALEONTOLOGY.—

Before proceeding to a consideration of the classifications adopted by modern geologists, a rapid sketch will be presented of the progress of the science in the United States. In the latter part of the last and early part of the present century papers upon geological subjects occasionally appeared in the volumes of the philosophical society of Philadelphia, the "Transactions of the Boston Academy," and in other scientific journals. The character of these papers is almost exclusively descriptive. There is, however, a theory of the earth proposed by Franklin in the "Philosophical Transactions" of 1798. The 6th volume of the same journal presented the paper of Mr. William Maclure, read Jan. 20, 1809, entitled "Observations on the Geology of the United States, explanatory of a Geological Map." The author of this paper had undertaken a more arduous and gigantic work even than that which was occupying William Smith of England; it was no less than a geological survey of the United States alone and at his own expense—a work which entitled him to the appellation he has received of the father of American geology. In this pursuit he crossed the Alleghanies no fewer than 50 times, visited almost every state and territory in the Union, and for years continued his labors mostly among those who could have no appreciation of his objects. He had visited nearly all the mining districts of Europe, and was hence well qualified, for one of that period, to recognize the corresponding formations of the two continents. He traced out the great groups of strata then designated, as the transition, secondary, and alluvial, in their range from the St. Lawrence to the gulf of Mexico. The tertiary, however, he did not recognize, owing to the absence of the chalk formation, the upper member of the secondary, which in Europe, being largely developed and most conspicuous, marks the strata of more recent origin lying above it as tertiary. He continued his explorations after this report, and in May, 1817, presented another to the society, accompanied by a colored map and sections. His observations were also extended in 1816 and 1817 to the Antilles, and a paper upon the geology of these islands was published in the 1st volume of the "Journal of the Academy of Natural Sciences." Prof. Silliman of New Haven, educated to the profession of the law, was induced by President Dwight of Yale college to qualify himself for the departments of natural science, particularly chemistry; and with this view he spent some time previous to 1806 in England and Scotland. In Edinburgh he became familiar with the discussions of the Wernerians and Huttonians in that transition period, as he styles it, between the epoch of geological hypotheses and dreams, which had passed by, and the era of strict philosophical induction, in which the geologists of the present day are trained. The interest excited by this controversy could not fail to direct his tastes toward the new science, and he returned to become its zealous promoter, for half a century

or more aiding to elucidate the geology of his country, inspiring the enthusiasm of others, and furnishing in the "American Journal of Science" an organ for the diffusion of scientific knowledge. At that period (1804-'5), he states, geology was less known in the United States than mineralogy. Most of the rocks were without a name, except so far as they were quarried for economical purposes, and classification of the strata was quite unknown. Dr. Archibald Bruce of New York commenced in 1810 the publication of a journal devoted principally to mineralogy and geology, the earliest purely scientific journal, as Prof. Silliman remarks, supported by original American communications. It was well received at home and abroad, but appeared only at wide intervals, and did not reach beyond the 4th number. The mineralogical collections at the principal colleges, and others belonging to scientific men mostly in New York, promoted inquiry and observation concerning the geological relations of the minerals and their distribution. The admirable treatise on mineralogy by Prof. Parker Cleaveland, published in 1816, fostered while it gratified this spirit of inquiry. In 1818 the brothers Prof. J. F. Dana and Dr. Samuel L. Dana published a detailed report on the mineralogy and geology of the vicinity of Boston. In the same year the "American Journal of Science" was first published, which has continued ever since to be the chief periodical American recorder of the progress of the sciences. The next year the American geological society held their first meeting at New Haven, where they continued to meet annually for several years afterward. The importance of geological explorations, with the view of thereby ascertaining the agricultural and mineral capacities of large districts, was beginning to be appreciated by communities and public bodies. In 1820 a geological survey of the county of Albany, N. Y., was made under the direction of the agricultural society of the county by Prof. Amos Eaton and Dr. T. R. Beck. Two years afterward Rensselaer and Saratoga counties were also thus explored. Prof. Eaton was also engaged by Gen. Stephen Van Rensselaer to make at his expense a geological survey of the country adjacent to the Erie canal. The result of this was published in 1824 in a report of 160 pp. 8vo., with a profile section of the rock formations from the Atlantic ocean through Massachusetts and New York to Lake Erie, the Rev. Edward Hitchcock furnishing many of the details through Massachusetts. The first geological survey made by state authority was that of North Carolina in 1824 and 1825. The progress of these public undertakings is presented in the table upon the following page. The names are of the principal geologists, and most of the assistant geologists who reported under their own names. Beside these public surveys are others of importance made in connection with the government explorations between the Mississippi and the Pacific. Those of Schoolcraft, Nicollet, and Fre-

mont are particularly worthy of reference. Nicollet, an accomplished astronomer from Savoy, devoted 5 years, from about 1833, to explorations made at his own expense in the western territories; and from 1839 to the time of his death in 1843 he was in the service of the U. S. government preparing a map of these territories, which was published. Explorations have been recently made in connection with the survey of the Pacific railroad across the Rocky mountains, and in California by Jules Marcou, W. P. Blake, Dr. Antisell, and Dr. Newberry. American geology has also been greatly elucidated by the labors of private explorers, especially by Lyell in his two visits to the United States. Agassiz's contributions to its natural history are highly important for their geological bearings, likewise the earlier investigations in comparative anatomy of Dr. R. Harlan and of Dr. S. G. Morton, and those more recently made by Dr. Jeffries Wyman. Mr. Isaac Lea and Mr. William C. Redfield have made valuable contributions to the science from original investigations. For the grouping and identification of the members of the palæozoic formations over their wide range from the seaboard to the Rocky mountains, American geology is largely indebted to the labors of Prof. James Hall of Albany, who has acquired the most exact knowledge of their fossils, and materially advanced the science of palæontology. Our knowledge of the growth of coralline structures and their relation to the production of the calcareous formations of remote periods, as well as of other kindred geological subjects, has been greatly extended by the elaborate treatises of Prof. James D. Dana embodying the results of his observations made on the U. S. exploring expedition of Com. Wilkes from 1838 to 1842. The British provinces of North America have been explored by private enterprise and public patronage. A notice of the mineralogy and geology of Nova Scotia, with illustrations and a geological map, by Dr. O. T. Jackson and Francis Alger, Esq., of Boston, was published in the "American Journal of Science," 1828-'9; and in 1831 the same memoir, extended by further observations collected in a second visit to Nova Scotia, appeared in the "Transactions of the American Academy" at Boston. Lyell also has described interesting features exhibited in the coal measures of this peninsula. Extensive surveys have been made in Nova Scotia by Prof. Dawson, now of the McGill college, Montreal, and his work entitled "Acadian Geology" appeared in 1857. New Brunswick authorized a survey, the report of which was published by A. Geener in 1839. Canada also passed a similar act in Feb. 1845, and Sir W. E. Logan has been actively engaged in carrying out this great work; his reports, accompanied by those of his assistants, T. Sterry Hunt, A. Murray, and others, having annually appeared since 1847. Newfoundland has been surveyed, under the government of the island, by Mr. Jukes, who has since had charge of the geological survey of Ireland.

Public geological surveys.	Years.	Chiefs of survey, &c.	Reports.
North Carolina.....	1824-'25	Denison Olmsted.....	2 annual.

—From the time of Werner's system of the rocks, the classification of the formations has been subject to continual modifications; and many conventional or partial terms of distinction have been adopted, some of which still continue in common use, though not always strictly definitive. Thus, the rocks are frequently spoken of as either stratified or unstratified, the former being understood to comprise all those formations plainly due to sedimentary deposition, and the latter the granites and crystalline rocks, which present no distinct lines of stratification, but on the contrary forms and structures that imply the operation of other agents than those which produced the other class of rocks. The distinction is an excellent one, inasmuch as the names are simply descriptive and entirely free from any implication of relative age or position or mode of origin; but it is imperfect, as the crystalline rocks sometimes appear to be

stratified, and the lowest stratified formations lose their distinctive features as they assume in the class sometimes called metamorphic the forms and crystalline structure of the unstratified rocks. The term primary, much in use for the granitic rocks, is objectionable, as it implies priority of time in their production; and these rocks, as is abundantly proved, have in many instances assumed the position and structure in which they are found long after the deposition of some of the sedimentary rocks that repose upon the flanks of their mountain masses. Those of Mont Blanc and of part of the central axis of the Alps even invade strata of the tertiary epoch. (See ALPS.) The name igneous is also an objectionable designation, as it assumes a questionable theoretical origin, at least for many of the rocks that have been thus classed; and moreover, it must either admit the products of modern volcanoes into the same

group, or exclude them from a designation to which they are eminently entitled by assigning them to the special group termed volcanic. To avoid this, the theoretical term hypogene (Gr. *ὑπο*, under, and *γενναω*, to produce, to bear) has been applied to the class, which implies that the rocks included in it were produced in the interior; and Lyell has with the same idea given them the name Plutonic. But distinctions based on such principles have not been generally accepted, and in their place the great divisions most likely to remain are those founded upon the presence or absence of organic remains, and upon the peculiar character of these when present. Thus the term azoic (devoid of vestiges of animated nature) is a comprehensive designation, applicable to all the non-fossiliferous rocks. Hypozoic of Mr. John Phillips may be preferred to it, as introducing a distinction between the ancient non-fossiliferous rocks and the modern volcanic productions. Palæozoic (Gr. *παλαιος*, ancient, and *ζωον*, an organic being) is applied to the formations which rest upon the azoic, and are distinguished by containing vestiges of the most ancient organic forms. It extends upward, including the coal formation and the overlying permian or magnesian limestone group. The designation metamorphic group, which is retained by many geologists (not, however, as a distinct class), comprises a series of micaceous, talcose, hornblende, and clay slates, crystalline limestones, and quartz rocks, which appear to be the lower members of the palæozoic series changed by some cause so as to assume a structure more or less crystalline, and lose all trace of the fossils they once contained. In several instances fossils peculiar to the lower palæozoic rocks have been found in them, but the identity of the formations was generally considered as established before this collateral proof was discovered. The cause of the metamorphism has until within a few years been attributed to the action of intense heat induced by proximity to the mountain masses of the so called igneous rocks when these were in a state of fusion. Not only, however, is this questioned by some of the most distinguished geologists and chemists, but even the igneous nature of the granitic rocks is disputed; and chemical action of saline solutions, aided it may be by moderate degrees of temperature, is referred to as a sufficient and more probable agent in the production of the crystalline rocks and in metamorphosing the stratified. The German chemist and geologist Gustav Bischof is the most zealous advocate of this view, and indeed carries it so far, that we are brought back to the time of Werner and the production of all rocks, except the modern volcanic, by precipitation from solvent fluids. Similar views are entertained by Profs. J. D. Dana, James Hall, and T. Sterry Hunt; and they are so ably supported by appeals to the solvent powers of fluids, and the chemical compositions of the various rocks and their constituent minerals, that the opinions of geol-

ogists will unquestionably be materially modified respecting the previous condition of many of the crystalline rocks. Bischof's great work presents the most complete exposition of these views. It is entitled *Lehrbuch der chemischen und physikalischen Geologie* (Bonn, 1854), and has been translated into English by Benjamin H. Paul. The subject may also be studied in Delesse's papers in the *Annales des mines*, in Dana's "Mineralogy," vol. i. p. 226 (4th ed. 1854), in the reports of the Canadian geological survey, and in Leasley's "Iron Manufacturer's Guide" (New York, 1859), p. 361 and elsewhere. For the next great division above the palæozoic, and including as its uppermost member the cretaceous formation, the name mesozoic (Gr. *μεσος*, middle) has been proposed by Mr. Phillips, the English geologist, and cainozoic (Gr. *καινος*, recent), for the tertiary formations; and these terms are now used to some extent as synonymous respectively with secondary and tertiary. These last names, however, are by no means given up, and to complete the series the term primary is removed by M. Boué from its former inappropriate place, and applied to the palæozoic class; an arrangement approved by Lyell, who to prevent confusion sometimes adds to it the epithet fossiliferous. Confusion, however, may also occur from another source, for the fossiliferous rocks from the base of the series to the chalk having originally all been classed as secondary, it is still common to speak of those below and including the coal measures as the lower secondary, and of those above including the chalk as the upper secondary—a convenient distinction, originally applied, we believe, by Prof. H. D. Rogers. The formations belonging to the present epoch are sometimes classed as quaternary, recent, post-tertiary, or post-pliocene. The subdivisions of the several classes have been established by the investigations of different geologists in different countries, and those adopted by the English geologists are recognized in the United States. The new subdivisions required in our own groups are in the palæozoic series, and in adding below them two other groups determined by the Canadian geologists. The upper of these is called the Huronian, the lower the Laurentian. The conglomerates and limestones of these ancient formations both testify to an origin derived from preëxisting formations. Thus the products of sedimentary deposition are carried back far into the domain where until of late Pluto held undisputed sway. Certain obscure quasi-coraline forms discovered in the Laurentian rocks, together with phosphate of lime, a mineral often of animal origin, and the recent discovery of fossils in gneiss in North Carolina, point even to the possibility that these most ancient groups of stratified rocks may finally come to be added to the palæozoic class.—The following abridged scheme presents the most important divisions in the order of arrangement of the formations from the recent to the most ancient, as now generally recognized:

Class.	Group.	European divisions.	Examples and localities of American equivalents.	
TERTIARY or CAINOZOIC.	POST-TERT.	Alluvium. Post-pliocene.	Modern deposits of rivers and lakes; peat beds, &c. Delta of the Mississippi, &c. Bluffs of the Mississippi; loess.	
	PLIO-GENE.	Newer pliocene, or pleistocene. Diluvium. Older pliocene.	Boulder-drift formation; sands and clays of Lake Champlain and the St. Lawrence river; valley of middle California, auriferous beds. Eastern Virginia and North Carolina.	
	MIO-GENE.	Miocene.	Martha's Vineyard, Long Island, New Jersey, sands and clays of Richmond, Va., and near the coast line of North Carolina, South Carolina, and Georgia, Kansas, Nebraska, California.	
	Eocene.	Eocene.	New Jersey, S. of the Potomac, near the coast, to Texas; Central Georgia; Claiborne beds, Alabama; southern California, Pacific slope.	
SECONDARY or MEOZOIC.	CRETACEOUS.	Maastricht beds. Upper white chalk. Lower white chalk. Upper greensand. Gault. Lower greensand. Wealden.	The group is largely developed in New Jersey, Georgia, Alabama, Mississippi, Arkansas, Texas, New Mexico, and the high plains E. of the Rocky mountains. The fossils generally refer the divisions to the upper part of the group; but in western Iowa, Kansas, and Nebraska, to the lower. It furnishes many calcareous beds, but no genuine chalk.	
	JURASSIC.	Purbeck beds. Portland stone. Kimmeridge clay. Coral rag. Oxford clay. Great or Bath oolite. Inferior oolite..... Lias.	Black hills, E. slope Rocky mountains. Connecticut river sandstone, the "middle secondary red sandstones" of New Jersey, Pennsylvania, and Virginia. Coal fields near Richmond, Va., and North Carolina.	
	TRIAS.	Upper, middle, and lower.		
	PERMIAN.	Permian, or magnesian limestone.	South-eastern Illinois, Iowa, N. E. Kansas; &c.	Rogers's series.
PRIMARY FOSSILIFEROUS, or PALÆOZOIC.	CARBONIFEROUS.	Coal measures. Millstone grit, or conglomerate. Carboniferous limestone.	The anthracite and bituminous coal fields, excepting those of Richmond, Va., and North Carolina. The floor of the eastern coal measures. Subcarboniferous limestone and red shales.	Seral. XII. Umbriel. XI.
	DEVONIAN.	Upper. Middle. Lower.	{ Gray sandstone. } Catskill group. { Red sandstone. } Chemung group. Portage group. { Hamilton group. } Genesee shale. Moscow shale. Marcellus shale. { Corniferous limestone. } { Schoharie grit. } { Oanda-gall grit. } { Oriskany sandstone. }	{ Vespertine. X. } { Pionet. IX. } { Vergent. } { Cadent. } { Post-Meridian. } VIII. Meridian. VII.
	SILURIAN.	Upper. Wenlock.	{ Upper pentamerus limestone. } { Ekerinal limestone. } { Delthyris shaly limestone. } { Lower pentamerus limestone. } { Stromatopora limestone. } { Tentaculite limestone. } Onondaga salt group. { Niagara limestone. } { Niagara shale. }	{ Pre-Meridian. } { Scalent. } VI.
		Middle. Upper Llandovery. Lower Llandovery.	Clinton group. Medina sandstone. Onondaga conglomerate.	Surgent. V. Levant. IV.
		Lower. Caradoc or Bala beds. Same and Llandovery flags. Maclure beds of N. W. of Scotland. Lingule flags.	{ Hudson river slates. } { Utica slate. } { Trenton limestone. } { Black river limestone. } { Bird's eye limestone. } { Chazy limestone. } { Calcareous sand rock. } Potsdam sandstone.	Matinal. III. II. Primal. I.
	AZOIC.		Huronian.	
	CAIN.	Oldest gneiss of Scotland.	Laurentian.	

The mesozoic division is most largely developed in Europe, and the names are of English formations. The palæozoic groups, though distinguished by names of British origin, are found in the United States and Canada much more fully developed, so that there are many divisions of them not recognized in Europe. The American arrangement is chiefly that of the New York geologists; the equivalent names and numbers of Prof. Rogers are also introduced in a separate column. Different sections of a vast area like the United States will necessarily have local arrangements of these formations, differing from any standard that can be proposed. Thus, by reference to the article LEAD, it will be seen that the lower and middle silurian assume different features in Iowa and Missouri from those of the same group in New York. The first, however, having been studied and determined, will continue to be referred to as the best known system. For more particular accounts of the formations the reader is referred to their names as alphabetically arranged in other portions of this work. In this arrangement no place is found for the granites, sienites, porphyries, and other crystalline rocks, formerly regarded as constituting the floor upon which the stratified rocks are built up, as well as introduced among the strata of different periods. They are no longer placed at the base of the formations, for the reason that their subjacent position is no longer admitted; and it is not now believed that deep borings wherever made must terminate in this class of rocks. Consequently, like the volcanic rocks they cannot appear in an arrangement based on the order of production, as to time, of the formations.—New divisions in the classification of the stratified rocks may be established on different grounds, as by a marked difference in the fossils of contiguous groups and a change in their mineralogical structure, accompanied with a want of conformity in the stratification; as when the layers of the upper group, approaching a horizontal position in their arrangement, repose upon the upturned edges of the lower. Between the production of these two groups there must have been an interval of time longer or shorter, separating the date of the one from that of the other; a period which elsewhere may be represented by long series of formations. Such instances are of frequent occurrence. The three great divisions of the fossiliferous rocks are distinguished, each by its peculiar collection of organic remains, indicating as many complete renovations of the animal kingdom in the history of the globe. The palæozoic contain few if any species in common with the mesozoic, nor these formations with the cainozoic. The last in its oldest groups presents an entirely different fauna from that of the newest cretaceous, and in them first appear living species of shells in small proportion with the extinct, but marking the dawn, the *æra*, of the present order of animal life; whence Lyell's division of eocene for these strata, and the two subsequent divisions of miocene and pliocene, the lower of these

presenting a less, and the upper a greater proportion of recent than of extinct species of shells. But, as remarked by Prof. James Hall, these strong lines of demarcation disappear as absent members are discovered in new localities; and as the sequence is thus made complete the changes in the fauna lose their abruptness. The line between the cretaceous and tertiary, he adds, is most difficult to draw by fossils.—The thickness of the formations is an element of no consideration in their arrangement. It must necessarily vary for the same group with the locality in consequence of the lenticular form essential to the strata; and again, some formations may have been the product of short periods of time and of slowly acting causes of accumulation of their strata, while others continued to be produced during long periods by rapidly acting agencies. But thickness is of special interest in tracing the distribution of formations over wide areas, and thus determining the direction whence came their materials, and that toward which the formation thins away.—It is often a matter of inquiry how strata, many of which are evidently of a superficial nature, can be collected in piles amounting to several miles in thickness; and how such an extent of vertical accumulations can ever be known and measured. Coal beds are understood to have been deposited, each one originally at the surface, yet they are repeated at intervals of variable distances apart amid parallel layers of sandstones, shales, and limestones, either one of which may occupy from a few feet to 100 or more in its recurrence. Sandstones like those of the Connecticut valley, containing tracks of land animals, are found in beds of several hundred feet in thickness, each layer of which must have been at the level of the tide when it received the tracks, which were soon covered by the accumulating sands. The only explanation for such phenomena must be that the surface was gradually subsiding during the periods of these accumulations. The times of slow subsidence were represented by the gathering of the fine sediments or the growth of the coal plants; and those of rapid subsidence by the inflow of the coarse sand and pebbles, which now form the beds of sandstone and conglomerates. Thus the strata continued to be piled upon each other so long as the same system of operations lasted; and thus it was that the palæozoic rocks which constitute the Appalachian system reached the aggregate thickness in some portions of their range of not less than 85,000 feet. When uplifted to form the hills and valleys of a continent, their horizontal arrangement is disturbed, the strata are turned upward so as to present disrupted ends and edges, and by their sloping and undulating position each in its turn is brought to the surface, and all may be measured, some in one locality, and some in others. Subsequently to this uplifting, denuding forces have been in action, removing immense portions, chiefly of the most elevated masses, and building up in more recent seas newer formations from the

wreck of the old in the same manner that these had been produced. Thus after a systematic plan, and with evident provision for the future wants of man, the various useful materials of all the strata are brought within his reach.—The successive introduction and distribution of organic beings is perhaps the most interesting subject developed by geological research; but in this article little more space can be devoted to it than to present the order in which the principal groups appeared. The most ancient forms of animal life found in the lowest fossiliferous rocks are a few mollusca, crustacea, annelida, and zoophytes; the mollusca represented by *lingula* and *obolus*; the crustacea by trilobites; the annelida by *colithus*; and the zoophytes by graptolites, and 2 species named by Prof. Forbes *Oldhamia*, found in the slates referred to the Cambrian group on the coast of Ireland, opposite Anglesea. Of plants the only representatives are fucoids. Fishes, not with bony skeletons, but of cartilaginous structure, first appear in the upper members of the silurian. Some land plants are also met with in the same group. Orinoidea and corals have become very abundant, and marine mollusca of almost every order. In the United States and other parts of the world similar groups of fossils characterize the silurian. Fishes with bony skeletons, true vertebrata, first appear in the coralline formation of the upper Helderberg; in these, land plants too are first met with. In the Catskill group are found genera of fishes peculiar to the old red sandstone, the upper devonian of England. This formation in Great Britain presents the first reptiles, and these are of lacertian character; in it are also found coniferous plants of the same genera with some afterward met with in the carboniferous group. The organic remains, and especially the fishes of the devonian, the first true vertebrate forms of animal life, are ably described in the works of Hugh Miller. These works give a permanency to the name of old red sandstone, which is little descriptive of the contemporaneous formation of the more slaty and calcareous strata in the county of Devon and other regions, where the group is more extensively developed than in Scotland and the north of England. In the United States, tracks of reptiles are first met with in the sub-carboniferous red shales. (See FOSSIL FOOTPRINTS.) The carboniferous group is distinguished for the multitude and size of its terrestrial plants, a wonderfully luxuriant flora, and altogether peculiar to this era. Prof. Göppert has distinguished 934 species of plants, divided as follows: *cellulares*, including the fungi, algae, &c., 19; *vasculares*, 915, of which 772 are cryptogamous plants, or ferns, calamites, and asterophyllites, and 94 are phanerogamous plants, as cycads, conifers, &c. Insects are detected with these, as extinct species of beetles, crickets, cockroaches, &c. The vestiges of marine mollusca, corals, and fishes, preserved in the sandstones, shales, and limestones of this group, indicate the existence of broad

archipelagos, subject to frequently varying relations between the areas above and below the level of the waters. Reptiles are found related to the batrachians on the one hand and to the so called sauroid fishes on the other. The trilobites, which from the silurian have gradually lessened in number as compared with other fossils, disappear, and their place is supplied by the kindred genus *limulus* or king crab, a family still represented in our own seas. About 1,050 species of this group have already been described. The vegetable and animal remains of the permian group strongly resemble their congeners of the carboniferous epoch, and some species are common to both formations. The cephalopoda, represented in the coal measures by 160 species, appear in the permian group only in a single nautilus. The reptiles are mostly of a higher order than the more ancient forms. Some are thecodont saurians, one species allied to the living monitor. With the permian all the ancient species of animals disappeared, and the fauna of the trias which succeeds is represented by entirely new forms. This is more particularly a German group, and receives its name from its triple division of *Keuper*, *Muschelkalk*, and *bunter Sandstein*, the last resting on the permian. It abounds in remains of reptiles and fishes, and contains tracks of gigantic batrachians. In its uppermost portion have been found in Würtemberg the earliest vestiges of mammalia, molar teeth of a solitary small marsupial, named by Plieninger, its discoverer, *microlestes antiquus*. Prof. Emmons has also discovered in the Chatham coal fields of North Carolina, in strata probably of the epoch of the keuper, the jaws of another minute mammal, which he calls *dromotherium syleestra*. In Frome, Somersetshire, teeth of marsupial mammals have very recently been found in strata supposed to be of the same age with the German keuper, and one closely resembles the mammal relic of the Würtemberg locality. These occurrences are the more remarkable, as no other mammal remains are found till near the base of the cretaceous formation, with the exception of two species of marsupials in the English oolite. The red sandstones of the United States referred to the period of the upper trias or lower jurassic have afforded few fossils, but some of them are exceedingly interesting. These are the footprints of birds and reptiles already referred to, the former being the earliest vestiges of the high class of animals to which they belong. Beside these, the formation affords some plants, mostly terrestrial, a few shells, crustacea, thecodont saurians, and several fishes, most of them of the genus *catopteris*. The coal formations of S. E. Virginia and of North Carolina, on about the same geological horizon as the red sandstone, present a flora distinct specifically, and in part generically, from that of the true carboniferous epoch. The most abundant forms are gigantic zamites and equisetums. The stigmaria, sigillaria, and lepidodendra have entirely disappeared. Several species, as the *equisetum*

columnare and others, are found in the oolitic sandstones of Whitby in Yorkshire. Some saurian teeth are met with, and relics of fishes. The shaly beds also contain numerous delicate shells, called *posidonomia*, which may perhaps have belonged to the crustacean genus *estheria*. The jurassic group is of interest for the increasing variety of organic relics it presents. Its deposits afford evidence of estuaries and of tides, and in England of alternations of fresh water with salt and brackish waters. New and various forms of animal life appear, from the huge saurians to minute insects, the wing cases and other relics of the latter being sometimes so abundant as to give a peculiar character to the calcareous strata in which they are found, and cause some of these to be distinguished by the name "insect limestone." The reptiles are strange forms of *ichthyosauri*, or fish lizards, some more than 24 feet in length, and *plesiosauri*, 11 feet long, animals fitted for living in the sea, and yet for breathing air like the cetacea. Pterodactyles, or flying lizards, tortoises, crocodiles, and other reptiles, appear in this group. In the Stonesfield slate of the Bath oolite several specimens of jaws have been found, which are referred to 2 varieties of mammifera, the one named *phacolotherium* belonging to the marsupials, and the other, called *amphitherium*, representing the placental insectivora; another species of the placental mammalia, named *opalotherium*, has also been found in the middle Purbeck beds of the same group. A remarkable distinction is observed by Brongniart in the flora of the several divisions of the stratified rocks. The period of the primary fossiliferous he styles "the age of acrogens;" that of the secondary up to the cretaceous "the age of gymnogens;" and that of the cretaceous and tertiary "the age of angiosperms." In the lower cretaceous members leaves of dicotyledonous angiosperms are met with among the coniferæ and cycadaceæ, and their proportion increases in the newer strata as the gymnogens diminish. In the wealden are found teeth and bones of terrestrial reptiles of extraordinary size and character. The iguanodon is supposed to have attained a length of 50 to 60 feet, and its teeth indicate herbivorous habits, and are worn by mastication like the teeth of herbivorous mammals. The shells of the wealden of Kent, Sussex, and Surrey are fresh water, referring the formation to fluvial origin. The fossils of the cretaceous formation above the wealden are almost wholly of marine character. The chalk and other calcareous rocks belonging to it, like the coralline structures of modern seas, abound in shells and zoophytes of great variety, and teeth of sharks and other fishes. Relics of turtles, saurians, and pterodactyles also occur in it. Lyell found 5 out of 60 New Jersey cretaceous shells identical with European species of the formation. These were *ostrea larva*, *O. vesicularis*, *gryphea costata*, *pecten quinque-costatus*, and *belemnites mucronatus*. In both countries these species

have a great vertical range, and might therefore be expected more than any others to be found in distant parts of the globe. Still a remarkable similarity is found in the general character of the group of fossils of the formation in the two continents. More than 10 European species have been found among less than 100 forms from the cretaceous strata of Texas. In the lower tertiary we first meet with a few testacea which we recognize as living; and the number of recent species, as before remarked, gradually increases with the later members of the formation. The lowest division, the eocene, is distinguished in the Paris basin for the great variety of its organic remains, among which are found productions of the sea alternating with those of fresh water and of the land. Skeletons of birds and of quadrupeds are preserved in wonderful perfection in the beds of gypsum which are quarried for the manufacture of plaster of Paris. Of 50 species of quadrupeds, nearly $\frac{2}{3}$ are pachydermata; one species of dog, a weasel, a squirrel, an opossum, and a bat, have also been recognized. All these species, however, as well as those of the birds, fishes, and reptiles, are extinct. The eocene beds of the United States east of the Mississippi abound in marine fossils alone, and though no terrestrial mammalia or land quadrupeds have been found in them, vestiges of cetacean mammalia are not rare. In Clarke co., Ala., the colossal bones of the zenglodon are a common feature in the calcareous strata of this formation. Lyell speaks of the vertebral column of one skeleton more than 70 feet in length at one locality which he visited, and of another 50 feet long. From the collections made at Claiborne more than 400 species of marine shells, echinoderms, and fishes have been determined, but only 8 or 10 of these are recognized as European. In the miocene deposits, which succeed, the number of recent species of shells is less than of the extinct; but a decided approach is perceived in the fauna toward the modern types. In France, to the south of Tours, are found in the faluns referred to this formation remains of mastodons and of extinct species of the horse, hippopotamus, rhinoceros, deer, and of the cetacea, as the morse, sea-calf, lamantine, and dolphin. The miocene beds of the southern Atlantic states, regarded as nearly equivalent to the faluns of Touraine, have furnished about 200 species, comprising mollusca, crustacea, corals, several fishes and reptiles, and one or two cetacea; about 20 per cent. of the shells and corals belong to recent species. In Nebraska the strata of this period, which have also been regarded as belonging to the upper eocene, have afforded bones of a number of extinct ruminant and other quadrupeds, which have been described by Dr. Leidy of Philadelphia. The deposits were of fresh water character, furnishing several fresh water shells and a fresh water crustacean. Far up the Missouri river, near the Yellowstone, similar deposits are known, and in these have been found land and fresh water shells, a few of marine

character; also remains of plants, saurians, turtles, &c. It is remarked that the eocene and miocene of the Atlantic states contain in all their numerous organic remains only about 2 or 3 species to the hundred in common; a fact indicative of the lapse of a considerable period between the completion of the one and the commencement of the other, during which no strata were deposited in that region. With the progress to later members of the tertiary, the similarity of the animal vestiges, especially of the testacea, to living forms rapidly increases. Of the larger land quadrupeds the species and many of the genera even, as of the mastodon, were lost before the present epoch. In some of the comparatively modern beds of this group found in Georgia between the Altamaha and Turtle rivers, containing shells of the same species with those inhabiting the neighboring waters, are found remains of the extinct species of the horse, hippopotamus, bison, elephant, mastodon, megatherium, and mylodon. Remains of the same elephant and mastodon are also found in New Jersey and New York beneath the beds of peat lying in the upper portion of the pleistocene drift. The genera of fossil shells peculiar to the principal geological divisions are thus given by Woodward in his "Manual of the Mollusca." Some of the genera named have a wider range, but are found most abundant in the division with which they are included in the table. Such is the case with the belemnites. The names in italics are of existing genera.

Divisions.	Genera and Subgenera.
PLIOCENE.	<i>Argonauta, Strombus, purpura, trophon, Yoldia, tridacna, Oliva, verticordia.</i>
MIOCENE.	<i>Spirulirostra, sturlia, vaginella, ferrussina, Halla, proto, Deshayesi, nio, caesidaria, Carolina, Grateloupia, artemis, lape, Jovannetia.</i>
Eocene.	<i>Beloptera, lychnus, megaspira, Glandina, typhs, volutithes, clavella, pseudoliva, seraph, rimella, conorbis, strepsidura, globulus, phorus, velates, chiloconcha, volvaria, lithocardium, terebina.</i>
UPPER CRETACEOUS.	<i>Belemnites, conoteuthis, turritites, pyrochoceras, hamites, scaphites, pterodonta, dinulla, tylostoma, Acteonella, globiconcha, trigonosemus, magas, lyra, Neithes, inoceramus, hippurites, caprina, caprotina.</i>
LOWER CRETACEOUS.	<i>Crioceras, toxoceras, hamulina, baculina, regulensis, caprinella, sphaera, thetia.</i>
UPPER JURASSIC.	<i>Cocconeuthis, acanthoteuthis, leptoteuthis, nautilus, spinigera, purpurina, nerinea, neritoma, pteroperna, trichites, hypotrema, diceras, trigoma, jachyrisma, Bowerbia, Tancredia.</i>
LOWER JURASSIC.	<i>Belemnites, beloteuthis, geoteuthis, ammonites, alaria, trochetoma, rimula, pleolus, cylindrites, Waldheimia, thecodium, spiriferina, ceromya, gryphus, hippopodium, cardinia, myoconcha.</i>
TRIAS.	<i>Ceratites, naticella, platystoma, Konnokia, cyrtia, monotis, myophoria, pleurophorus, opia.</i>
PERMIAN.	<i>Camarophoria, sulcosteges, strophalosia, myalina, Bakewellia, axinus, Edmondia.</i>
CARBONIFEROUS.	<i>Nautiloceras, discites, goniatites, Porocella, naticopsis, platyschisma, metoptoma, producta avicula-pecten, anthracocella, conocardium, Sedgwickia.</i>
DEVONIAN.	<i>Bactrites, gyroceras, clymenia, apiceras, serpularia, spirifera, unites, merista, Davidsonia, calceola, stringocephalus, megalodon, orthonota, pterinea.</i>

SILURIAN. { *Actinoceras, phragmoceras, trochoceras, asco-ceras, theca, holopella, Murchisonia, atrypa, Retzia, cardiola, clidophorus, grammysia, gonioleptus.*

CAMBRIAN. { *Camaroceras, endoceras, gonioleptus, pterotheca, Macleura, raphistoma, holopea, platyceras, ortholina, platystrophia, porambonites, pseudo-crania, ambonychia, modiolopsis, lyrodesma.*

By turning back to the groups of strata and the vestiges of organic beings which they successively introduce, one cannot fail to perceive a marked progress in the condition of the surface of the earth, adapting it for higher organizations of animal life, and at the same time the appearance of these forms, as it seems by successive acts of creation. The broad seas of the lower silurian epoch, stretching over large portions of the globe, contain their peculiar types of marine life, crustacea, cephalopoda, and algae, all perfect of their kind, and as admirably constructed as their representatives found in modern seas. To these invertebrata next appeared in the deposits left by the waters of the devonian period the first vertebrate animals in the form of fishes. Aquatic reptiles succeed; and when in the luxuriant vegetation of the carboniferous epoch land appears, it is productive only of those forms of animals adapted to moist tropical districts scarcely elevated above the sea level. No vestiges of mammalia or of birds yet appear. The reptiles first attain their highest development in the lias and the oolite periods; and at last in the tertiary epoch, distinguished for its broad areas of dry land, the mammalia are found in numbers and variety which continually increase up to the introduction of their highest representative, man. This general scheme of the creation is established by most careful geological investigations conducted in various parts of the world. New discoveries may somewhat modify its minor features, but where uniformity in the operations of nature is found to obtain so generally, and no exception is detected, it is unphilosophical to refuse to accept the evidence because the whole has not yet been submitted to our examination.—In what manner new species have been introduced is a question that has occupied the closest study of many philosophers, but which remains in the same obscurity as the origin of individual life. Some, adopting the views of Geoffroy St. Hilaire, contend that the ancient species were the progenitors of all that succeeded and that now live. This view was supported by De Lamarck, and ingeniously sustained by the authors of the "Vestiges of Creation." But the arguments adduced to support the doctrine of the so called transmutation of species, which if established destroys the real existence of species in nature, were based on assumed facts, or carried out to an extent unwarranted by any of those within our experience. The changes of form to which species are subject in successive generations by change of circumstances are very limited, and appear to be restrained within certain bounds by constant laws. No instance has ever been established of one species being succeeded after many

generations by another even of the same genus or family; in the immense collections of fossil remains which have been most carefully studied no evidence of a passage of this character has been proved. On the other hand, instances are everywhere encountered in which new types of life appear, not through any gradation, but so far as we can judge by a sudden step, the strange being having none of its genus, order, or even class to point back to as its possible progenitor. Moreover, the fossil remains present no evidence of a progress in the succession of species to those of higher organization leading to higher types of life. On the large scale a progress to higher orders is perceived, as already observed; but the earliest silurian trilobite exhibited in the structure of that most delicate organ, the eye, the same complexity and wonderful perfection that is perceived in the eye of the fly and butterfly of the present day, and which is perhaps unequalled in living crustacea; while the fishes possessed as perfect an organization as that belonging to any of the later members of the same families.—In the sketch thus far presented of the development of geological science no special attempt has been made to distinguish between the subjects relating to descriptive and those belonging to the department of physical geology. As the phenomena introduced suggested the causes of their production, these have been incidentally considered, and thus it is that some of the grandest subjects of physical geology, especially those of a speculative nature, have escaped notice. In both departments important omissions must be observed, which in part at least may be attributed to the necessary limits imposed upon the present article, and to the treatment of their subjects under separate heads. Thus the phenomena of some of the mighty forces which disturb the arrangement and modify the structure of the strata are partially treated in the articles **CENTRAL HEAT, EARTHQUAKE, ETNA, and VOLCANO**; of those which distributed some of the comparatively recent deposits, in **ALLUVIUM, DILUVIUM, and GLACIER**; and the mode of production of many calcareous beds is explained in **ATOLL, and CORAL**. The subject of **MINERAL VEINS** is treated under its own head, as also in the articles **COPPER, GOLD, IRON, LEAD, &c.** But for a satisfactory elucidation of these and other topics reference must be made to works specially devoted to their treatment. In Lyell's "Principles of Geology" may be most profitably studied the subject of geological dynamics. The work is expressly an attempt to explain the former changes of the earth's surface by the operation of causes now in action, and consequently comprehends a minute investigation of the changes taking place both in inorganic and organic nature. The movements going on upon the surface and coming under the observation of man are considered sufficient, if extended through indefinite periods of time, to account for all the phenomena presented in the strata of the earth, without the necessity of attributing to the forces any greater intensity of action than they

now exhibit. It is shown that even the climate of any part of the world may be materially modified by the varying conditions of portions of its surface, whether covered by water or raised high above the ocean's level. The existence of elevated continents in polar latitudes, and at the same time of seas spreading over the equatorial regions, would necessarily produce a cold climate over large portions of the earth; while, the conditions being reversed, a tropical climate might reach into high latitudes, and plants of kindred character to those that make up the ancient coal beds might again thrive where the forest remains of the carboniferous epoch now lie buried beneath perpetual snow. It is not perhaps extravagant to suppose that such conditions of the surface may in former times have obtained; for the rocks themselves testify, in the marine fossils they contain, that almost all parts of the earth's surface have been beneath the level of the sea; and changes of level, similar to those which have been observed by man, either suddenly taking place, as in the rising at different times of the coast of Chili, or by a constant imperceptible motion like that which has continued for centuries to raise the coast of Sweden, and that again which in like manner carries down the coast of Greenland—such as these, if continued during the long geological periods, would suffice to produce the required conditions. The geological formations in the phenomena of their deposition demand these periods, perhaps fully as long as could be required on the supposition that no other and no more energetic causes than those now in action had influenced their production. But those who oppose this theory maintain, that although periods of time of illimitable duration must be admitted, it is unphilosophical to make the intensity of the forces in action, as observed in the short period of man's existence, a measure of the intensity of the same forces in all past epochs. In particular the elevation of mountain chains, it seems to many, must have exhibited more energetic action than has ever been displayed in the experience of man. Several so called theories of elevation have been applied to explain these phenomena. Von Buch and Élie de Beaumont regarded many mountain masses as "craters of elevation," produced by the expansive force of elastic vapors beneath, lifting up and breaking open the horizontal strata, and leaving them arranged in conical form, or sloping on each side from a central line. Thus Etna and Vesuvius, they contended, were lifted up by a single movement; and the same force of elastic vapors might in like manner have been the agent which suddenly uplifted the mountain chains. (See **ÉLIE DE BEAUMONT**.) These views are opposed by many serious objections. The theory of the professors Rogers is referred to in the article **EARTHQUAKE**.—The views of Prof. James Hall upon this subject have not been before published. They are the result of extended observations, continued for many years, of the strata in their most dis-

turbed condition in their eastern belt, and of the same formations in the western states, where they lie nearly horizontally, and are filled with organic remains. Toward the west the thickness of the sedimentary deposits is known to gradually decrease; over the great western plateau there is no evidence in the formations of metamorphic action, and trap dikes are of very rare occurrence. Approaching the Appalachian range, the strata become more variously folded and contorted, and the structure of the rocks more compact, in some instances crystalline, and their cleavage more irregular. The introduction of crystalline minerals, and a thicker bedding of the limestones, also bear evidence of progressive metamorphism, which as traced eastward is accompanied by a more broken topography, and ridges and valleys of more marked outlines, corresponding in direction to the synclinal and anticlinal axes. Neither in New England, from the sections across this portion of the range made by Prof. Hall in 1843 and 1844, nor in Pennsylvania and Virginia, according to the observations of other geologists, is there an appearance of any great central axis of older date than the rest, or of igneous rock, theoretically regarded as the necessary nucleus of a mountain chain. On the contrary, many of the highest ridges are composed of strata lying in synclinal axes, the newest, and not the oldest, forming the summits. Seeing that these phenomena could not be explained by reference to any central axis or other theory of elevation, Prof. Hall was led to adopt entirely new views of the origin of mountain chains, after submitting the results of his own widely extended observations and those of others to careful study. The strata uniformly increasing in thickness toward the mountain ranges was an effect evidently not due to their folding. The Appalachian chain, composed of paleozoic strata, coinciding in direction with the original line of greatest accumulation of deposits of that period, the currents which produced them must have had the same direction; and on each side the sediments must have gradually thinned away in finer materials. The anticlinal and synclinal axes having also this same general direction, and the action of metamorphism traceable along the same lines increasing with the increasing thickness of the rocks, and with the frequency of the plications of the strata, Mr. Hall infers that the mountain ranges result from the original accumulation of sediments, their height depending on the quantity of this original deposit, and that the elevation of mountains can nowhere be so great as the original thickness of the sediments. By subsequent action their surface has been abraded and their forms modified; but the greatest portion of the mass still lies below the horizon of our observations. This conclusion is quite true respecting the Appalachian chain, where the sedimentary deposits present a thickness varying from 80,000 to 50,000 feet, while the summits range only from 4,000 to 6,000

feet in height. The same views, sustained by a large accumulation of facts, he applies to the Rocky mountain range, where the sediments of later periods increase the elevation, and the same principles are believed by the author of the theory to be applicable to all mountain ranges, the elevations being dependent on the amount of original accumulation of sediments; where these deposits consist of the aggregate of several geological periods, all the higher will be the mountain chains. The mountains of the northern United States and Canada, capped by rocks of the Laurentian age, never reach the elevation of those of the Appalachian, composed of the paleozoic formations; and the height of these is surpassed by the summits of the central and western portions of the continent, capped by strata of still later age. In the Alps and other ranges of great elevation the summits are sometimes composed of still more modern formations. These views would restore to some extent the opinions of the older geologists, who always regarded mountain chains as part of the continental elevation. The hitherto unexplained feature of the plication of the strata in numerous nearly parallel axes are accounted for by Mr. Hall thus. It is well understood that the ocean of these ancient deposits must have been always shallow, notwithstanding the immense thickness they attained; and that its bed must have been more or less continually subsiding. This movement would involve a lateral pressure, which would result either in ruptures below or a sliding upon each other of the middle strata, or else cause the upper portions of the mass to become folded in lines parallel to the line of subsidence, which would be the original line of accumulation. The same cause that raised the more elevated portions uplifted the thinner and less disturbed deposits, the whole being a continuous elevation. The present Gulf stream of the Atlantic and other great oceanic currents are collecting ranges of sediments, which if uplifted with the whole oceanic area would no doubt present features similar to those of existing mountain chains from which the direction and force of the currents might be traced.

GEOMETRY (Gr. $\gamma\eta$, the earth, and $\mu\epsilon\rho\epsilon\sigma\alpha$, to measure), the science which treats of order and proportion in space. One of the oldest and simplest of sciences, it is nevertheless variously defined, and its fundamental definitions are variously announced, according to the philosophy of the writer. Thus it has been defined, in accordance with the etymology of the word, as the science of measurement, as though it dealt with material things. A portion of space such as might be filled by a solid body is itself called in geometry a solid. The boundaries of this geometrical solid are called surfaces. But geometrical surfaces may be conceived as not bounding solida, but as simply separating space from space. They constitute one form of the zero of space, having length and breadth without thickness; they are a zero of solidity, but have a magnitude of their own, called super-

ficial area. If a surface be limited in extent, the boundary on any side is a line. A line is the 2d form of the zero in space, being zero not only in solidity, but in superficial area, and having a magnitude in length alone. A line may be conceived as not bounding a superficies, but as being simply a fixed zero of the 2d form. If the line be limited in extent, its extremities are points. A point may also be conceived as a zero in space, of the 3d order, a zero not only in solidity and in superficies, but in length also—having no magnitude or proportion, and retaining only order, or position, as the sole element of its existence. In the position of points, the difference in the direction of a first and second point from a third is called an angle, and the natural unit for measuring angles is oppositeness of direction. We have here all the elemental conceptions of geometry, viz.: a point, a line, a surface, a solid, and an angle, that is, order of position; and magnitude, or proportion of distances. From these definitions as data a vast amount of geometrical science may be deduced by the laws of logic; and geometry has by some been regarded as a purely logistic science, which merely develops the truths implied in its definitions. Geometers themselves, however, usually regard these definitions as descriptions of realities independent of matter; to them a sphere is more real than a globe, and their science is daily discovering sublime truths of the relations of space, not implied in these elemental conceptions, but only connected with them by indissoluble ties of mutual relationship.—The history of geometry is divided by Chasles, in his valuable *Aperçu historique des méthodes en géométrie*, into 5 periods. The 1st is that of the Greek geometry, lasting about 1,000 years, and ending about A. D. 550. Then after a pause of 1,000 years, the 2d period began in the revival of ancient geometry about 1550. A 3d period or epoch was marked in the beginning of the 17th century by Descartes' co-ordinates. The 4th period was inaugurated in 1684 by the "sublime invention" of the differential calculus. The 5th era is marked in our own century by Monge's "Descriptive Geometry," by which he developed the idea of reducing problems of solid geometry to problems in a plane. Since Chasles' *Aperçu historique* was published, a 6th period has been introduced by the publication in 1858 of Hamilton's "Quaternions." Greek geometry began, it is said, with Thales and Pythagoras, who obtained their first ideas from the Egyptians and from India. The Pythagorean school demonstrated the incommensurability of the diagonal of a square with its sides, and investigated the 5 regular solids. They had some knowledge of triangles and circles, and possibly were acquainted, as it is affirmed they were, with the fact that the circle and the sphere are the largest figures of the same perimeter or the same surface. About a century after Pythagoras, the great Plato and his disciples commenced a course of rapid and astonishing discoveries,

through the study of the analytic method, conic sections, and geometric loci. The ancient analytic mode consisted in assuming the truth of the theorem to be proved, and then showing that this implied the truth only of those propositions which were already known to be true. In modern days the algebraic method, since it allows the introduction of unknown quantities as data for reasoning, has usurped the name of analytic. Conic sections embrace, as is well known, the study of the curves generated by intersecting a cone by a plane surface. Within 150 years after Plato's time this study had been pushed by Apollonius and others to a degree which has scarcely been surpassed by any subsequent geometer, and his works, embracing his predecessors' discoveries as well as his own, proved 19 centuries afterward the foundation of a new system of astronomy and mathematics. Geometrical loci are lines or surfaces defined by the fact that every point in the line or the surface fulfils one and the same condition of position. The investigation of such loci has been from Plato's day to the present one of the most fruitful of all sources of geometrical knowledge. Just before the time of Apollonius, Euclid introduced into geometry a device of reasoning which was exceedingly useful in cases where neither synthesis (i. e. direct proof) nor the analytic mode is readily applicable; it consists in assuming the contrary of your proposition to be true, and then showing that this implies the truth of what is known to be false. Contemporary with Apollonius was Archimedes (287–212 B. C.), who introduced into geometry the fruitful idea of exhaustion. By calculating circumscribed and inscribed polygons about a curve, and increasing the number of sides until the difference between the external and internal polygons becomes exceedingly small, it is evident that the difference between the curve and either polygon will be less than that between the polygons themselves; and this method may be continued by increasing the number of sides, until the difference between the curve and the polygon is as small as we please. Hipparchus in the 2d century before Christ, and Ptolemy in the 2d century after Christ, applied mathematics to astronomy; at the date of the latter writer the doctrine of both plane and spherical triangles had been well discussed by Theodosius and Menelaus. Vieta (A. D. 1540–1603), to whom we principally owe the invention of algebra, enlarged Plato's analytic method by applying algebra to geometry. To him also is due the merit of discovering the ratio of the increase of angles and the increase of their sizes. Kepler (1571–1630) introduced into geometry the idea of the infinitesimal, thus perfecting the Archimedean exhaustion; and also first made the important remark which leads to the solution of questions of maxima, that when a quantity is at its highest point its rise becomes zero. To Kepler we owe also one of the first examples of a problem of descriptive geometry, in the graphic solution of an eclipse of

the sun. Soon after Kepler, Cavalieri published (1635) his *Geometria Indivisibilibus*, a further step in the road from Archimedes' exhaustions to Newton's fluxions. Roberval gave a method of drawing tangents identical in its philosophy with fluxions. Fermat (who shares with Pascal the credit of inventing the calculus of probabilities) introduced the infinitesimal into algebraical calculation, and applied it with great success to geometrical questions. Pascal, applying his wonderful genius to the conic sections, anticipated some of the latest inventions by his famous theorem concerning the relation of 6 points arbitrarily chosen in a conic section. But most wonderful of all the geometrical inventions of the 17th century was that of Descartes, published in 1637; it consisted simply in considering every line as the locus of a point whose position is determined by a relation between its distances from 2 fixed lines at right angles to each other. The relation between these distances, being expressed in algebraical language, constitutes the equation of the curve. By later geometers this method has been generalized so that the distances may be measured from any fixed point or line, and measured in a straight line or in a given curved line; or instead of some of the distances, directions or angles may be introduced. For a majority of the most important cases, Descartes' coordinates are, however, still the best. Huyghens, whose treatise on the pendulum is ranked by Chasles with Newton's *Principia*, making a glorious combination of Descartes' methods with those of his predecessors, added to geometry the beautiful theory of evolutes, which are the curves formed by the intersection of straight lines at right angles to a given curve; and he applied it not only to the pendulum, but to the theory of optics. Soon after (1686) Tschirnhausen published a wider conception of the generation of curves by straight lines. His famous caustics were made by the intersection of reflected or refracted rays of light; and he proposed other curves made by a pencil point stretching a thread whose ends were fastened, and which also wrapped and unwrapped from given curves. About the same time also De la Hire and Le Poivre invented, independently of each other, modes of transforming one plane curve into another, by making the given curve a peculiar basis for the locus of a new curve. They thus transformed the circle into all the conic sections, without any reference to a cone. The great Newton also invented a means to the same end, so that the consideration of the ellipse and parabola became independent of that of any solid. Thus these methods, especially that of Le Poivre, anticipated descriptive geometry, and perhaps prepared the way for it. In 1700 Parent generalized the method of Descartes from representing a line to representing a curve surface by an equation between the distances of a point in the surface from 3 given planes, at right angles to each other; but this was not methodically arranged, and it was left for Clairaut, in 1781, to finish

this great step. Meanwhile Newton's fluxions and Leibnitz's differential calculus had come into use, and Newton, Maclaurin, and Cotes had made the most exhaustive investigation into curves of the 8d degree, and many fine discoveries in regard to curves in general. The enthusiasm which Newton's example aroused in England and Scotland for pure geometry was followed by a lull of about a century, when Monge by his "Descriptive Geometry" gave the whole study new life. The essence of descriptive geometry lies in the transmutation of figures, the reduction of geometry of 3 dimensions to geometry in a plane. One beautiful example of this branch of science may be found in linear perspective, which simply projects the points of a solid upon a plane, by straight lines of light from the eye. Carnot, at the beginning of this century, in his "Geometry of Position" and "Theory of Transversals," also introduced valuable methods; in the first showing how to indicate the direction of lines more exactly by the use of positive and negative signs, and how to use the idea of motion in a more effective manner than before in geometry; in the second introducing that general form of the theory of transversals, i. e., of the intersections of a system of lines by one not belonging to the system, which Chasles employs so happily in his *Géométrie supérieure* (1852). This writer develops two principles in the correspondence of figures: one, the principle of duality, by which for a given figure a second is found such that points, planes, and straight lines in one correspond to planes, points, and lines in the other; the second, the principle of homography, by which for any figure a second is drawn such that points, planes, and lines in one correspond to points, planes, and lines in the other; the utility of each being to transfer the demonstrations of truth in one figure to the problems of another figure. In our own time many new ideas have been published, which cannot yet be properly appreciated, because their actual fruitfulness has not been tested. Sir William Rowan Hamilton of Dublin, in attempting to develop a science of time, discovered it to be a pure algebra; and pushing his inquiries further, formed an algebraic notation for questions of space, which promises to become the most valuable geometrical engine yet invented. His "Lectures on Quaternions" (1853) develop the mode of using algebraic notations with a geometrical meaning, as follows. A line, perfectly expressed, has direction as well as length. The sum of 2 sides of a triangle is therefore equal to the 3d side; in other words, you arrive at the same point whether you go through 2 sides in succession, or only through the 3d side. Quotient is the expression of ratio, and the ratio of 2 lines if perfectly expressed must give their directions as well as length. The quotient of one side of a triangle divided by another must therefore be a quaternion, that is, embrace 4 numbers, one to express their ratio of length, one their angle with each

other, and 2 to express the position of their plane. The value of these quaternions may be made apparent by a simple case. Suppose 3 lines of equal or unequal length to radiate from a fixed point. Let the quaternion quotients obtained by dividing either of these lines by another be denoted by r , p , and q . As these express all the relations of the rays, of the 3 extremities, and of the angles made by them when of equal length, it is evident that a single equation between r , p , and q may express all the theorems both of plane and spherical trigonometry. Prof. Peirce of Cambridge, Mass., in 1858 proposed a general method of expressing curves, which promises to lead into unexplored fields. He defines a curve by an equation between angles which it makes with 2 known curves allowed to vary either in parameter or in some other mode so as to produce an intersection of each other at each point of the 3d curve. Thus, to take a familiar example, the conic sections may be defined by their making equal angles with straight lines radiating from 2 fixed points; and for another, the logarithmic spiral makes with straight lines radiating from a point, and circles concentric round that point, angles whose ratio is constant.—The relation of geometry to other sciences is, like that of the other mathematics, twofold, giving and receiving. To mechanics it gives the only possibility of understanding the laws of motion, and from mechanics it receives the conception of moving points, lines, and surfaces, and thus generating lines, surfaces, and solids. To chemistry it gives the only means of investigating crystallization, polarization, &c., and from chemistry receives new ideas concerning the symmetry of planes. To botany and zoology it gives the laws of form, and from them receives those highest problems of morphology which are as yet barely touched upon by the masters in either of these sciences. In the study of the human spirit, geometry proposes the question of the foundations of belief, by giving the first examples of demonstration; and from the psychological inquiries thus aroused, geometry has received from age to age the new conceptions which have been the base of many new methods of investigation and proof. To theology geometry gives definite conceptions of the order and the wisdom of the natural creation, and *a priori* demonstrations of the optimism of actually existing material laws; and from theology she has been stimulated to many fresh exertions in the investigation of these teleological questions.—The beginner in geometry will find many text books, from which he may select according to his taste. None is perhaps more popular than the "Elements of Geometry and Trigonometry," by Prof. Charles Davies, from the works of A. M. Legendre (New York, 1856). Much more condensed and suggestive is an "Elementary Treatise on Plane and Solid Geometry," by Prof. Benjamin Peirce (Boston, 1858). An easier treatise than either of these, by Prof. G. R. Perkins, has been published in

New York. The true style of Greek geometry may be found in Playfair's "Euclid," of which there is a New York edition. For advanced studies the following list of works is recommended: "Modern Geometry," by Mulcahy (London, 1859), giving some idea of the new methods, but not employing analytical geometry; "Elementary Treatise on Plane and Spherical Trigonometry," and "Elementary Treatise on Curves, Functions, and Forces," by Benjamin Peirce (Boston, 1858), giving in its most condensed form the necessary introductory knowledge of the notation of trigonometry, analytical geometry, and the calculus; "Analytical Geometry," and "Differential and Integral Calculus," by Charles Davies (New York, 1855), giving a more popular expression of the same knowledge; a "Treatise on Conic Sections, containing an Account of some of the most important Modern Algebraic and Geometric Methods," by G. Salmon (London, 1855); a "Treatise on the Higher Plane Curves," by the same author; *Traité de géométrie supérieure*, by M. Chasles (Paris, 1832); *Mémoire de géométrie sur les propriétés géométriques des coniques sphériques*, by Chasles (Brussels, 1831; soon after translated into English); *Aperçu historique sur l'origine et le développement des méthodes en géométrie, particulièrement de celles qui se rapportent à la géométrie moderne; suivi d'un mémoire de géométrie sur deux principes généraux de la science, la dualité et l'homographie*, by Chasles (Brussels, 1837; translated into German, Halle, 1839; a work which will richly repay a close study); *Systematische Entwicklung der Abhängigkeit geometrischer Gestalten von einander, mit Berücksichtigung der Arbeiten alter und neuer Geometer über Porismen, projective Methoden, Geometrie der Lage, Transversalen, Dualität und Reciprocität*, by Steiner (Berlin, 1822); *Traité des propriétés projectives des figures*, by Poncelet (Paris, 1822); *Des méthodes en géométrie*, by Serret (Paris, 1855); *Mémoire sur les lignes du second ordre*, by Brianchon (Paris, 1817), and his *Mémoire sur les courbes de raccordement* (Paris, 1823); four books of Plücker of great merit, the *Analytische geometrische Entwicklungen* (2 vols. Essen, 1828-'31), *System der analytischen Geometrie auf neuer Betrachtungsweise gegründet und insbesondere eine ausführliche Theorie der Curven dritter Ordnung enthaltend* (Berlin, 1835), *Theorie der algebraischen Curven gegründet auf eine neue Behandlungsweise der analytischen Geometrie* (Bonn, 1839), and *System der Geometrie des Raumes in neuer analytischer Behandlungsweise, insbesondere die Theorie der Flächen zweiter Ordnung und Classe enthaltend* (2d ed. Düsseldorf, 1852); *Géométrie de position*, by Carnot (Paris, 1803), his *De la corrélation des figures de géométrie* (Paris, 1801), and his *Mémoire sur la relation qui existe entre les distances respectives de cinq points quelconques pris dans l'espace; suivi d'un essai sur la théorie des transversales* (Paris, 1806, and 4to. 1815); *Géométrie descriptive*, by

Monge, and his *Application de l'algèbre à la géométrie* (Paris, 1829, 1838); *Développements de géométrie, avec des applications à la stabilité des vaisseaux, aux déblais et remblais, au défillement, à l'optique, &c., pour faire suite à la géométrie descriptive* de G. Monge, by Dupin (Paris, 1813); Sir Isaac Newton's *Enumeratio Linearum Tertii Ordinis*; Euler's *Introductio in Analysin Infinitorum* (London, 1797; translated into French, Paris, 1796); "Lectures on Quaternions, by Sir William Rowan Hamilton, containing a systematic statement of a new mathematical method, of which the principles were communicated in 1843 to the royal Irish academy, and which has since formed the subject of successive courses of lectures, delivered in 1848 and subsequent years, in the halls of Trinity college, Dublin; with numerous illustrative diagrams, and with some geometrical and physical applications" (Dublin, 1853).

GEORGE (Lewis) I., king of Great Britain and Ireland, first sovereign of the Hanoverian line, born in Osnaburg, May 28, 1660, died near the same place, June 10, 1727. By the act of settlement, passed in 1701, the British crown was entailed on Sophia, electress dowager of Hanover, granddaughter of James I., and her posterity. Sophia died June 8, 1714, and so missed the throne to which she had been called by only 54 days, Queen Anne dying Aug. 1. George Lewis, her eldest son, was, like his father, the elector Ernest Augustus, partial to military pursuits, which he commenced at the age of 15. He served in Greece, Hungary, Germany, and Flanders, and was present at the great battle near Vienna in which John Sobieski defeated the Turks. He also served under William III., and took part in the battles of Steenkerke and Lauden. He succeeded his father in 1698. He sought the hand of Anne, daughter of the duke of York, in 1681, but failed; and in 1682 he married his first cousin, Sophia Dorothea, daughter of the duke of Zell, whose affections, if he ever possessed them, were soon alienated by his infidelities and brutality. Sophia Dorothea was suspected of an intrigue with a Swedish nobleman, Count Philip Christopher von Königsmark, and was arrested and imprisoned for 32 years in the castle of Ahlden, her supposed lover having previously been put to death. The elector was proclaimed king of Great Britain and Ireland immediately on the death of Anne, arrived in London Sept. 20, 1714, and was crowned Oct. 20. The majority of the English people were undoubtedly opposed to his accession, but the activity of the whigs was more than a match for the strength of the Jacobites and Tories. The rebellion of 1715, in Scotland and the north of England, was put down; and though there were many conspiracies entered into against him, and even foreign potentates and ministers planned his downfall, George I. was never in any danger of losing the throne to which he had been called by parliament. He was not a popular monarch, and the grossness of his tastes (he is said to have

been fond of nothing but punch and fat women) was not calculated to make his vices pardonable. Both he and his attendants regarded England as a land to be plundered. His quarrel with his son originated in politics, and dated back to years before the king's accession; but it was aggravated by the prince's attachment to his mother, the imprisoned Sophia Dorothea. After the family had secured the British throne, the father and son behaved toward one another quite decorously for a time, the prince acting as regent during the first of the many visits which the king made to Germany. This state of things did not last, and the king soon came to hate his son almost as bitterly as he hated his wife. There were separate courts, the prince of Wales residing at Leicester house, and the king declared that he should regard all who visited his son as his enemies, to be excluded from the royal presence. The quarrel became one of the scandals of the time, and as it was followed by similar quarrels in the royal family, the triumph of constitutionalism was coupled with domestic dissensions. The king connected himself with the whigs, whose long ascendancy in the 18th century dates from his accession. The ministry of 1714 contained such men as Townshend, Stanhope, Cowper, Halifax, Sunderland, and other eminent whigs. Robert Walpole, who was soon to be the leading minister, had at first no higher place than that of paymaster-general, and did not belong to the cabinet. His talent was so superior, however, that in 1715 he was made first lord of the treasury, which office did not then confer the premiership, though it was in his person that it finally became the first place in the ministry. The breach that took place in the whig party in 1717 caused Walpole, Pulteney, and others to resign their places, and the Stanhope-Sunderland ministry was formed. Previous to this the septennial act was passed, by which the legal existence of each house of commons was extended to 7 years, a proceeding that worked well, though it was in opposition to old whig principles. The new ministry formed the quadruple alliance, by which England, France, the empire, and Holland united to preserve the peace of Europe. The short war that followed was very humiliating to Spain. Admiral Byng annihilated the Spanish fleet at Passaro. The government was very strong both at home and abroad, all the plots in favor of the Stuarts having failed, while the schemes of Alberoni and Görtz had ruined only those who had formed them. A sort of reconciliation had been effected between the king and the prince of Wales. Everything appeared prosperous, when the bursting of the South sea bubble wrought the ruin of the ministry, and it was even expected that the king would abdicate. The ministry were held responsible, not only for the South sea act, which was indeed their work, but for the mad speculations that had followed its passage. Stanhope was seized with a fit while replying in the house of lords to an unjust attack,

and died; Oraggs, secretary of state, died of small pox, and Sunderland left the treasury. Walpole, who had not been in office when the act was passed, took the lead in the work of change, and was made Sunderland's successor. The latter soon dying, peace was restored, and Walpole's long turn of power began with a new house of commons, in which the now united whigs had a heavy majority. The hopes of the Jacobites had revived, and a plot was formed for an insurrection in 1722, which was detected, and Bishop Atterbury was banished for his part in it. Walpole's love of power, and resolution to monopolize it, led to dissensions in the ministry. Carteret was compelled to give up the place of secretary of state, and go to Ireland as lord lieutenant, where Swift had raised a storm against Wood's halfpence. Walpole was jealous of his relative Townshend, who had become conspicuous from the part he had in making the treaty of Hanover, by which an alliance was formed between England, France, and Prussia, in opposition to Austria, Russia, and Spain. The king did not like the measure, and Walpole disapproved of it because of the consequence it gave to Townshend; but the time had not come for an open breach between them. William Pulteney, so celebrated for his eloquence and his avarice, was removed from a petty office in the royal household, for his opposition to a motion for discharging the civil list debts. The union of Spain and the empire came near to bringing about a general war in the last year of George I., but Walpole, whose merit it was ever to prefer peace to war, averted the danger. At this time Bolingbroke, who had been allowed to return to England, though not to resume his former state, was engaged in strong efforts to overthrow Walpole. Having secured the interest of the duchess of Kendal, the king's mistress, he was confident of ultimate success with the king, who at first treated his representations of the evils that must follow from Walpole's continuance in power with contempt. But the reign of George I. was drawing to a close. He loved Hanover and disliked England, and often visited his German dominions, which gave rise to much animadversion from the Jacobites. On June 8, 1727, he left England for Hanover, accompanied by the duchess of Kendal and Lord Townshend. On the 10th, while in his carriage, he was seized with a fit, and died before the party could reach Osnaburg, though attempts were made to revive him after they arrived there, where his death is generally stated to have happened. He is said to have been fully impressed when he left England with the belief that he never should return, and among the gossip of the time was a story that he had been warned that he should not survive his wife a year; she died at Ahlden, Nov. 2, 1726. He was a man of moderate faculties, and but for the circumstance that his fortunes happened to be identified with those of the constitutional party in a great nation, he probably never would have been more heard of than a thousand other

German princes whose very names are unknown. He was a cruel husband, a bad father, and a vicious man, and yet by no means a bad sovereign; but this distinction was owing to the constitutional restraints that were imposed on him, and to the want of knowledge on his part of the nature of English politics and parties. The union of England and France, which was the chief event of the reign of George I., and which was brought about by the very party that had upheld the war policy in Anne's reign, shows a breadth of policy such as was not common in that age; yet it ought to be mentioned, that this alliance was dictated by the circumstances of both governments, it being for the interest of the Hanoverian dynasty and the whigs that the connection between France and the Stuarts should cease, and that the reliance of the Tories on that country should be broken up; while the hope of the duke of Orleans, then regent, that he might come to the crown of France, when he would need foreign support, made it equally for his interest that both England and Holland should be engaged on his side.

GEORGE (AUGUSTUS) II., son of the preceding and of Sophia Dorothea, born in Hanover, Oct. 30, 1683, died at Kensington palace, Oct. 25, 1760. But little is known of his early history, except that he was neglected by his father, and that he was brought up by his grandmother, the electress Sophia. He visited Holland in 1699, and in 1705 was married to Wilhelmina Dorothea Caroline, daughter of the margrave of Brandenburg-Anspach, a woman of marked character and superior talent. The next year he was made a peer of England, his chief title being duke of Cambridge, with precedence over the peerage. He made the campaign of 1708 under the duke of Marlborough, and conducted himself with great bravery at the battle of Oudenarde, having his horse shot under him. In the opposite ranks, and showing equal valor, was the pretender, son of James II. He accompanied his father to England in 1714, and took the titles of prince of Wales, and earl of Chester and Flint, Sept. 27. The quarrel between father and son broke out soon, and they hated each other cordially. The prince had been preferred by the electress Sophia to her own son, and that son was attached to his mother, two causes that sufficed to increase his father's original dislike of him; but political differences were the groundwork of the quarrel. The king also hated the princess of Wales, and was jealous of her popularity. So vindictive was his feeling, that he entertained a proposition, made by the earl of Berkeley, to carry off the prince to America, there to be so disposed of as never to trouble his father again. The king sought to deprive his son of all control of his children, and 10 of the 12 judges decided in his favor. A sort of reconciliation was effected in 1720, through Walpole's influence, but the parties hated each other as bitterly as ever, their formal intercourse being a hypocritical tribute to

public opinion. When he ascended the throne, George II. endeavored to transfer power to the hands of Sir Spencer Compton, but his incapacity was so evident that Walpole retained his place, the more easily that he was supported by Queen Caroline, who saw that he was the man for the times and for the dynasty. The coronation took place Oct. 11, 1727. The pretender, on hearing of the death of George I., had made some movements, and the Jacobites had their hopes roused, but the new king was not in the least disturbed thereby. The history of the first 14 years of the reign of George II. is that of the struggle of Walpole and the opposition, the fiercest civil political contest, unstained by blood, that England has ever known. The hopes that had been entertained of Walpole's overthrow, as a consequence of the death of George I., had been disappointed, and that great minister's power was now fixed on a firm basis, from which it could never have been shaken but for his jealousy of all able men. The new parliament contained an overwhelming ministerial majority, and the king soon became strongly attached to the minister both on personal and political grounds. The royal avarice was gratified and the royal ease consulted by the minister, and hence the king supported the latter with all his influence; but the support he received from the queen, who governed her husband without his knowing it, was of greater importance. George II. was as fond of Hanover as his father had been, and visited it often, to the disgust of his English subjects. He hated his son Frederic, prince of Wales, as bitterly as he had himself been hated by his father, and the queen shared his feelings in that respect. Frederic was not allowed to visit England until 1738. The fault was originally on the side of the parents, and the prince long bore the king's harsh treatment without complaint, and perhaps would have done so to the last if it had not been for the interest of the opposition to make him acquainted with his political importance, and to stir him to resentment, because the king supported Walpole personally. The first great act of this reign was the treaty of Seville, concluded in 1739, between England, France, Spain, and Holland, which was very advantageous to England, and by which Spain silently acquiesced in the English possession of Gibraltar. Walpole quarrelled with his colleague Townshend in 1730, and the latter resigned office, and retired altogether from public life. Walpole was supreme in the cabinet, and appears to have been disposed to make some improvements in the laws, and to correct abuses; but the virulence with which all his measures were opposed in parliament compelled him to be cautious. The use of Latin in the courts of justice was discontinued, and English substituted. The sinking fund, which Walpole himself had aided to establish, was now so encroached upon that it soon ceased to be of any value. The great contest on the excise question now commenced, and was the most remarkable incident of the first half

of the reign. The mere report of the intention to introduce a scheme of general excise caused alarm, and the opposition, which had been reduced very low, immediately became vigorous. The battle was fought with ability and courage on both sides, and though in some of its stages the ministerial majorities were 60, they finally fell to 16, in a house of commons which had given Walpole almost 200 majority on other questions. The bill was then withdrawn, greatly to the satisfaction of the people. The king was as much beaten as the minister, and they revenged themselves by dismissing from office, or from sinecure places, a number of distinguished noblemen who had been prominent in opposing the measure, the chief of whom was Lord Chesterfield. The election of 1734 resulted in the return of a strong Walpolian majority. The opposition sought the repeal of the test act, and were beaten by 128 majority. The gin act, which sought to do something to lessen drunkenness, was passed in 1736. The prince of Wales was married in 1736, and the question of his income afforded the opposition means to annoy the ministry, and caused the quarrel between father and son to become bitterer than ever. The queen died in 1737, recommending her husband to Walpole with her last breath. The opposition endeavored to have the army reduced in 1738, but failed. They then assailed the ministry because of its indifference to the outrages perpetrated by the Spaniards in America on Englishmen there trading. An arrangement made with Spain was unpopular. The ministerial majority was greatly reduced, but the minister was saved by the folly of his enemies, a number of whom seceded. The troubles with Spain went on, and war was declared against that country, Oct. 19, 1739. The ministerial strength now diminished, and the hopes of the Jacobites revived. The war was by no means brilliantly conducted. Anson's cruise in the Pacific and Indian seas revived the recollections of the Elizabethan age, and Vernon took Portobello; but the English failed at Oathagena, and also at Santiago de Cuba. The war of the Austrian succession began in 1741, and England was drawn into it. Parliament was dissolved, and the new elections took place under circumstances unfavorable to Walpole. When parliament assembled, the opposition found themselves in a majority, and after a hard battle Walpole gave way, much to the grief of the king, who continued to take his advice to the last days of his life. Sir Robert was created earl of Orford, and the attempts made to prosecute him fell through. Lord Wilmington became premier, and Carteret secretary of state. Success was ruinous to the opposition, which showed it could not administer affairs, though so eloquent in fault-finding. The public was greatly disappointed, and the refusal of the victors to repeal the septennial act, which had been the object of their especial indignation when out of office, caused much disgust. England had now become actively engaged in the

Austrian war, and sent a large force to Flanders, which did nothing. Some success was achieved by the navy, and a British squadron compelled Naples to observe a neutrality. The king, who was fond of military life, and personally brave, was desirous of placing himself at the head of an army, and a large German force was taken into English pay. This added to the hatred of Hanover already felt in England. The king joined the allied army, June 19, 1743, and 7 days later was fought the battle of Dettingen, in which the French were beaten, the monarch showing much courage. The death of Lord Wilmington led to Henry Pelham's elevation to the premiership, the king acting under the advice of Walpole. Carteret continued to manage foreign affairs, and was much liked by the king. The Hanoverian policy was still vigorously opposed, but the resolute conduct of France, the fear of invasion, and the revival of the Jacobite party, caused some remission of party feeling, and the adoption of strong measures by government, the whigs of all views uniting in their support. The French government called Charles Edward Stuart to France, and extensive preparations were made to invade England, which failed through the occurrence of a severe storm, the fleet being destroyed or dispersed. Lord Carteret, now Earl Granville, was compelled to leave the ministry, and Pelham forced the king to admit Chesterfield and some others of the old opposition to office. The Hanoverian policy was kept up, despite these changes, and England entered on an extensive system of German subsidies. Great preparations for the campaign of 1745 were made, but with no gain to England. The allies were beaten by the French at Fontenoy, when under command of the duke of Cumberland. Charles Edward landed in Scotland, was joined by many Highlanders and others, and, after occupying much of the ancient kingdom of his race, marched into England as far as Derby, when his leading supporters compelled him to retrace his steps. He had won the victory of Gladsuir, and it is now the current opinion that if he had pressed forward from Derby to London the capital would have fallen into his hands. George II., though very brave, and prepared to place himself at the head of his guards for a last fight, made preparations to fly. The rebels defeated the royal troops at Falkirk, but 3 months later their army was annihilated at Culloden. From that time dates the extinction of the Stuart party. The rest of the war was inglorious, and it was terminated by the treaty of Aix la Chapelle in 1748. For some years there was but little political discussion, and the opposition had dwindled into a small faction, headed by the prince of Wales, which became extinct soon after his death in 1751. Private bills excited more interest in parliament than those of a public character. An increase in the stringency of the mutiny bill, and the passage of a regency bill, caused some discussion. The reformation of the calendar was

effected in 1752, providing that the year should commence Jan. 1 instead of March 25. The bill for the naturalization of the Jews was passed in 1753, and, though one of the most creditable acts of English legislation, caused so much popular excitement that it was immediately repealed. The premier died March 6, 1754, and was succeeded by his brother, the duke of Newcastle, who found himself compelled to share power with others. His first ally was Henry Fox, afterward Lord Holland, and at a later day William Pitt. The 7 years' war began in 1756, and England was involved in a contest of the severest character with France, while at the same time she was the ally of Prussia, which was at war with France, Russia, the empire, and lesser powers. The contest extended over the world, and was marked by great actions in Europe, in North America, and in the East Indies. The early part of the war was inglorious to England, but shortly after the formation of the Pitt and Newcastle ministry in 1757, the genius of Pitt changed the fortune of the contest, and the English were triumphant in every quarter. Ample subsidies were furnished to Frederic of Prussia, so that he was enabled to make head against the coalition formed for his overthrow. An army of English and Germans defeated the French in Germany, at Orefeld, Minden, and elsewhere. North America was the scene of great operations, which ended in the expulsion of the French. An expedition to France, twice renewed, inflicted considerable damage on that country, destroying, among other things, the works at Oherbourg. The success of Clive laid the foundation of the British Indian empire. Senegal and Goree were conquered; and the victory of Admiral Hawke over Conflans, in the naval battle of Quiberon, established English supremacy on the ocean. Never had England stood so high as she stood in 1760. In the midst of these successes, forming so striking a contrast to most of his reign, George II. suddenly died, at the age of 77. He was a man of ordinary character, and never had been popular with his English subjects; but he had governed constitutionally, and in his reign the liberal polity was fairly established. The industrial system of England then began to display itself, and the world saw the first evidences of that power which was to receive a development so vast and unparalleled. Personally the monarch had little to do with these things, but he was the chief in the political system under which and through which they came to pass. As a despot he would probably have proved a bad ruler, for his tastes were arbitrary, and so were his acts when he was not restrained by law and circumstances; but as a constitutional sovereign he has a respectable place in history.

GEORGE (FREDERICK WILLIAM) III., grandson of the preceding, and son of Frederic, prince of Wales, and of Augusta of Saxe-Gotha, born June 4, 1738, died at Windsor castle, Jan. 29, 1820. He was not likely to be

well educated in the court of his father, nor did the death of that parent improve his prospects in that way. He was brought up more as a Stuart prince might have been than as the heir apparent to the throne of a constitutionally governed state. His disposition was both arbitrary and crafty, and the whole of his long reign, until the time that he lost his intellect, was passed in a continual combat against liberal ideas and institutions. At first he was popular. Young, a native of the country, and but little known to the people, his accession (Oct. 25, 1760) was hailed with loud rejoicings. This fair dawn was soon overcast, and for more than 20 years he was the most unpopular monarch of his time. He was married, Sept. 8, 1761, to the sister of the duke of Mecklenburg-Strelitz, Charlotte Sophia, the Queen Charlotte of 57 years, a marriage from which proceeded 15 children, all but two of whom grew up. The new king was averse to the system which his two predecessors had pursued, and was resolved upon being a king in fact as well as in name. To afford an opportunity to attempt the inauguration of the new system, it was necessary that peace should be restored, though the war was very popular, and Pitt, the war minister, was at the height of his power. The earl of Bute, long connected with the king's father and mother, was introduced into the cabinet, and ultimately became premier, and put an end to the war, though not until a new war had been made, in consequence of Spain having joined France. When the family compact was made between France and Spain, Pitt was for anticipating the latter, and commencing the war, but was overruled in the cabinet, where almost every man hated him because of his inordinate egotism and arrogance. He resigned his office, but the event showed the wisdom of his advice, for the conduct of Spain was such that England was compelled to declare war against her, Jan. 4, 1762. This war was a series of successes on the part of England. Havana was captured, with a large part of the island of Cuba, the Philippines were reduced, and treasure ships of immense value were taken from the Spaniards. The effect was to make the minister more determined than ever upon peace, which was finally brought about at Paris in 1763, on terms that were honorable to England, though party spirit caused them to be denounced as treacherous, insecure, and disgraceful. The king became unpopular, and the minister was the object of violence. The restoration of peace enabled the king to seek the development of his political plans, and for many years he was engaged in a warfare against those principles to uphold which his house had been called to the British throne, to the exclusion of the legitimate line. Ministry succeeded to ministry, the king hating all alike, with this difference, that he was more treacherous in his conduct toward the whigs than toward the Tories. Then it was that "the king's friends" were first heard of, a class of politicians who were neither whigs nor Tories, but who did the

king's work without inquiry, and constituted a political militia. The parliament was generally with the king, but the people were not; and so ready were the latter to oppose the monarch, that they made an idol of the worthless John Wilkes. It was while George Grenville was minister, in 1765, that the stamp act was passed, which threw the North American colonies into a blaze, and was the first in that series of acts which in their entirety make up the American revolution. At length, at the beginning of 1770, Lord North became premier, having been chancellor of the exchequer for some time, and he held the place for 12 years. The modern Tory party dates from that time as a powerful and efficient organization. The king ruled as well as reigned, and the attacks on American liberty were his acts, the guilt of the minister consisting in his being the tool, against his own convictions, of a master who was not always in possession of his reason. The dreariest period of modern English history is the time in which Lord North was prime minister. The American war began in the spring of 1775, and for 7 years the most desperate efforts were made to conquer the colonies, which in 1776 declared themselves independent states. Beside large bodies of English troops, and Tories and Indians recruited in America, thousands of German mercenaries were employed in the war, which was marked by just enough of success to encourage the king to persevere. Gradually other countries were drawn into the contest, until it had assumed a European character. War between France and England began in 1778, and Spain and Holland were soon ranked in the number of England's active enemies. The northern powers formed the armed neutrality. The combined fleets of France and Spain obtained command even of the English channel. Gibraltar was beleaguered by an immense fleet. The army of Burgoyne surrendered to the Americans in 1777, and 4 years later that of Cornwallis capitulated to the allied forces of America and France. The fortunes of England were never before so low, and though the successful defence of Gibraltar, and the naval victory won by Rodney over De Grasse, closed the war with some flashes of glory, the contrast between the state of things then and 20 years before was most humiliating to all reflecting Englishmen. The king was compelled to submit to a Whig ministry, headed by the marquis of Rockingham and Charles James Fox. Lord Rockingham's death caused the new ministry to fall to pieces, and power passed into the hands of the earl of Shelburne and the younger William Pitt. American independence was acknowledged, and peace restored, though the king was even then resolute to continue the contest, and talked of retiring to Hanover because of the coercion to which he was subjected. The Shelburne ministry was driven from power by the famous coalition of the Foxite whigs with the Tories who followed Lord North. The king hated this ministry intensely, and talked of going to Hanover more than ever, and

probably did not go because of the hint that while it would be easy to reach that country, it would not be so easy to get back to England. His submission was short-lived. The coalition broke down in an attempt to put a stop to the misgovernment of India. Its India bill passed the commons, but was thrown out by the lords in consequence of royal influence having been brought to bear on the minds of some of the peers. The king then dismissed the ministry, and placed Pitt at the head of his councils. After the new ministry had carried on a conflict with the coalition party in the commons until the latter had lost its majority, parliament was dissolved, and in the elections that followed the coalition was annihilated. The king was now as popular as formerly he had been odious, and the tory party commenced a reign of more than 40 years. The prince of Wales was now of age, and had commenced that loose life which has made his name and title by-words, and which was all the more distasteful to the king because the prince's associates were mostly whigs. As George I. had hated his eldest son, and George II. followed his father's example, so did George III. hate the heir apparent. Public affairs went on smoothly, save that the impeachment of Hastings, who was patronized by the king, was brought about by the aid of Pitt. In 1788 the king was severely assailed by that illness to which he was liable throughout his long life, and which finally rendered him incapable of attending to business. A fierce struggle was commenced between parties, the object of the whigs being to have the prince of Wales made king under the title of regent, should the royal illness continue, while the tories were determined materially to abridge the powers of the regent. The recovery of the king put an end to the contest. Immediately after his recovery occurred the commencement of the French revolution, an event that arrested his attention; and that great movement found in him the most determined of its enemies. Before the breaking out of the war with France, a dispute took place with Russia, the object being to prevent the conquest of Turkey by Catharine II. The opposition rallied and gained strength, but Turkey was saved. Another dispute occurred with Spain, but did not lead to war. The war with revolutionary France began in 1793; and though the English maintained their naval character, defeating the French on June 1, 1794, at the Nile on Aug. 1, 1798, and elsewhere, the Spaniards at Cape St. Vincent, Feb. 14, 1797, and the Dutch at Camperduin, Oct. 11, their military character was not raised by its events. The most arbitrary rule was established at home, and nothing but the firmness of English juries prevented the establishment of as complete a reign of terror in Great Britain as existed in France. Ireland was oppressed until she was goaded into rebellion, which was suppressed by measures as cruel and bloody as any perpetrated by the French republicans in La Vendée and Brit-

tany. The union between Great Britain and Ireland was effected in 1800, the parliament of the latter ceasing to exist, while she was allowed to send 100 members of the house of commons and 80 representative peers to the imperial parliament. Peace was made with France in 1801, though against the king's wishes, his opinion always being in favor of bloodshed, unless his enemy should unconditionally submit. The French had been driven out of Egypt, and Malta captured from them. The peace was but a hollow truce, and the refusal of the English to give up Malta led to the renewal of the war in 1803. The Pitt ministry had broken down, really on the question of peace with France, but ostensibly because of the king's bigotry, he refusing relief to the Catholics, though it had been understood it was to be granted as one of the conditions of the Irish union. Henry Addington became premier, and kept his post until after the renewal of the war, when Pitt returned to office. The threats of Napoleon to invade England, and the vast preparations he made for that purpose, caused the people to rally around the throne, and an immense force was on foot, of regulars, militia, and volunteers, while the navy was much increased. Spain was drawn into the war on the side of France, and their united fleets were destroyed at Trafalgar, which made England irresistible on the ocean, and settled the invasion question for that generation. For some time the war on the part of England was principally confined to the ocean, though she assisted the enemies of France with money. Such military expeditions as she fitted out were on a small scale, and mostly failed. In South America, in Egypt, in the north of Europe, her armies were either beaten or accomplished nothing; and it was not until the breaking out of the Peninsular war in 1808 that, under the command of Moore and Wellesley, they performed any thing worthy of the high name of their country. Pitt died in 1806, and the government passed into the hands of a coalition ministry, of which Lord Grenville and Mr. Fox were the chiefs. The object of the latter was the restoration of peace with France, but he died before any thing could be done. The coalition endeavored to grant some relief to the Catholics, but the king got rid of them, and a ministry of tories was formed, headed by the duke of Portland. This ministry was probably the worst England ever had, and though it succeeded in the attack on Denmark, taking possession of the Danish fleet, the immorality of that attack more than balanced its success. Operations in Spain and Portugal were badly conducted; and the Walcheren expedition in 1809, which might have struck a deadly blow at Napoleon's power while he was combating Austria on the Danube, was probably the worst managed undertaking mentioned even in English history. This failure led to the breaking up of the Portland ministry, for which the Perceval ministry was substituted, an improvement on its predecessor, inasmuch as Mar-

quis Wellealey took the foreign office. The commencement of the 50th year of the king's reign, Oct. 1809, was observed as a jubilee. There was little occasion for rejoicing. The war had failed utterly on land; France ruled almost the whole of continental Europe; the disputes with the United States threatened to add a new enemy to those England already had; while the conduct of some of the king's sons was flagrantly profligate. His 2d son, the duke of York, was compelled to resign the post of commander-in-chief, in consequence of the exposures made by Mrs. Clarke. In 1810 died the princess Amelia, the king's youngest and favorite daughter, and the king suffered so much from anxiety during her illness that he lost his reason for ever. More than once he had been raving mad, and it is doubtful if he ever was sane in a strict medical sense. The first indications of his disease appeared on the very day of the completion of the 50th year of his reign, Oct. 25, 1810. His reign ceased in fact from that date, but in law it lasted more than 9 years longer. The prince of Wales became prince regent, and after some coquetting with the whigs, gave his confidence to the Tories, who became more powerful than ever. The turn taken by foreign events favored them. The invasion of Russia by Napoleon took place at the very time the Liverpool ministry was formed, after Mr. Perceval's death. The battle of Salamanca, the first open military blow struck at Napoleon's power, was won by Wellington, July 22, 1812. During the next two years the English and their allies were everywhere successful, and a series of brilliant operations, illustrated by the victories of Vittoria, the Pyrénées, Orthez, Toulouse, and others, carried Wellington's army far into France, at the same time that the allies penetrated to Paris and compelled Napoleon to abdicate. The allied sovereigns, attended by many of their statesmen and generals, visited England in June, 1814; and that visit, and the restoration of peace to Europe, led to great rejoicings. England, however, was still at war, the United States having declared war with her, June 18, 1812, which was terminated by the treaty of Ghent, Dec. 24, 1814. At the congress of Vienna, which assembled to settle the condition of Europe, England was represented by some of her leading statesmen, whose purposes were better than their deeds, though a treaty was entered upon to coerce Russia, the principal parties to which were Austria, England, and France. The return of Napoleon in March, 1815, led to a renewal of the war with France, which was speedily terminated by the successes of the English and Prussians in Belgium, and the rapid advance of the victors to Paris, which surrendered July 4, 1815. Napoleon gave himself up to the English and was sent to St. Helena, the prince regent taking no notice of the letter written to him by the illustrious prisoner. These brilliant successes confirmed the power of the Tories, but domestic government became difficult from the

general spirit of discontent that followed the peace, and harsh legislation was resorted to; while opinion in England began to exhibit itself against the despotic theories and practices of the holy alliance. Lord Castlereagh, who had done more than any other Englishman except Wellington to bring about the fall of Napoleon, was the principal member of the cabinet, holding the office of foreign secretary, though Lord Liverpool was nominally premier, and he was known to sympathize strongly with foreign despots, and was very unpopular. Falling by his own hand in 1822, he was succeeded by Mr. Canning, when the policy of England became more liberal. In the mean time, George III. died, after a reign of 59 years, 8 months, and 4 days, the longest known in English history, and most fertile in events. The empire had been greatly extended, principally in the East; but to balance these gains, the American colonies had been lost as a consequence of the king's misconduct, and a new power was growing up in the West destined to spread free institutions over a continent, and to react upon Europe.

GEORGE (AUGUSTUS FREDERIC) IV., son of the preceding and of Queen Charlotte, born Aug. 12, 1762, died June 26, 1830. Nature endowed him with fair talents, and he had all the advantages of education. His youth promised well, but on attaining his majority he commenced a course of extravagance, often ending in debauchery, that contrasted strongly with the decorous life of his father. He joined the whigs, but rather because his father hated them than from attachment to their principles, as he failed them in hours of trial, and ultimately became an extreme Tory. The nation was scandalized at his excesses, the cost of which it had repeatedly to defray, though his income was ample even for one in his high position. In 1795, though he had been secretly married for some years to Mrs. Fitzherbert, he espoused his cousin, Caroline of Brunswick, neither from love nor from motives of state policy, but to get his debts paid. After living together for a year, during which their only child, the princess Charlotte, was born, they separated by common consent. Anxious for a complete divorce, the prince endeavored to prove his wife unfaithful; but at most she was guilty while in England only of imprudent acts, and her father-in-law always protected her, not only because he had caused the marriage, but because he hated her husband. It was not until he became regent in 1810 that the prince of Wales assumed a political character of importance, and he then gave himself up to the Tories. At the head of the nation during those years when the long war with France was brought to so brilliant a conclusion, he shared in the glories achieved by the genius of Wellington, but was never personally popular. His daughter, the princess Charlotte, died in 1817. He became king, Jan. 29, 1820, and soon was commenced that open persecution of his wife which agitated the whole country. A bill of pains and penalties was introduced into

the house of lords, charging the queen with adultery. The trial lasted for many weeks, and the bill passed to a third reading Nov. 10; but the majority for it was so small and public opinion so decidedly pronounced against the prosecution, that the government withdrew it. Nominally victorious, the queen was really beaten, and died of chagrin in less than a year. The king visited Ireland, Scotland, and Hanover, and apparently was popular. He was, however, greatly perplexed by politics. The progress of liberal opinions was making itself felt in England, and the ministry had to go with the world. Castlereagh's suicide and Canning's promotion were sources of much trouble to him. The foreign policy of Canning was eminently distasteful to one with whom Napoleon had pleaded in vain. When a French army, at the bidding of the holy alliance, entered Spain to restore absolutism, England was greatly moved, and probably nothing but financial considerations prevented war with France. When Portugal appealed for English aid against Spain, that aid was promptly given. The Greek revolution added to the interest which the English felt in foreign affairs from classical associations. Internal policy was liberalized. Peel led the way, though a tory minister, in meliorating the criminal law; Huskisson's commercial ideas began to make head; Brougham labored in the cause of education; and the work of Catholic emancipation went vigorously forward. The year 1824 was a period of great material prosperity, and was followed by a crash in 1825. Early in 1827 the duke of York, heir presumptive to the crown, died, and Lord Liverpool was incapacitated from further attention to business by illness. The contest that followed for the premiership ended in the triumph of Canning, whereupon 7 of his associates resigned, and he was compelled to reconstruct the cabinet, which he did on a liberal basis. He died, however, before he could accomplish any thing. His successor was Lord Goderich, whose ministry lasted but a few months, and was the weakest England had known for a long time. It was followed by the Wellington ministry, Jan. 1828, with the duke as first lord of the treasury and Peel as home secretary. This return of the tories to power was the signal for the revival of the emancipation agitation, and the Catholics proved successful in 1829. The ministry had to choose between giving up their principles and civil war, and they made the sacrifice required of them. The king, whose bigotry and dread of popular ideas increased with his years, stood out to the last against the current of opinion, but was forced to give way. The dissenters had previously been freed from disabilities. These acts, noble though they were, proved the ruin of the tory party, and so demoralized it that it could not stand before the feeling that was soon after roused over Europe by the French revolution of 1830. The king was taken seriously ill early in that year, and died June 26. The duke of Wellington, who was no flatterer, said of him after his death: "He

was the most extraordinary compound of talent, wit, buffoonery, obstinacy, and good feeling—in short, a medley of the most opposite qualities, with a great preponderance of good—that I ever saw in any character in my life." His short reign had been remarkable for the advances made in liberal sentiments, and for the many practical reforms which it had witnessed—changes with which the sovereign had little to do. The England of 1830 bore but small resemblance to the England of 1820, and still less to that of 1810, when, though as regent only, George IV. had commenced the life of a sovereign. He left no children of legitimate rank, and for the first time since the accession of the house of Hanover to the British throne a deceased king was not succeeded by son or grandson, the duke of Clarence, 8d son of George III., succeeding George IV. by the title of William IV.

GEORGE, prince of Denmark, born in 1653, died Oct. 28, 1708. He was the 2d son of Frederic III. and Sophia of Lüneburg. Upon the death of his father, war was renewed with Sweden, and the prince took part in his brother Christian V.'s campaign against Charles XI., when the rival kings commanded and fought in person. The prince is said to have gallantly seconded his brother's personal prowess. On July 28, 1683, he espoused the princess Anne of England, second daughter of the duke of York, afterward James II. She bore him 17 children, all of whom died before their mother's accession to the throne. The prince was wholly devoid of talent, as of ambition. "I have tried him drunk," said Charles II., "and I have tried him sober; and drunk or sober, there is nothing in him." He was, however, brave, good-natured, and humane; taking no part in politics, and deserting his unhappy father-in-law in the hour of need, chiefly by the desire and after the example of his wife. He had been brought into the conspiracy through her subservience to Churchill, the future duke of Marlborough, but his extreme insignificance rather excited the raillery of the king, even on this sad occasion. "After all," said James, hearing of his defection, "a good trooper would have been a greater loss." After the triumph of the prince and princess of Orange, Prince George was created by the new king duke of Cumberland, in acknowledgment of his coöperation in the great measure which had been achieved; and on the accession of his wife, the "good Queen Anne," to the throne, in 1702, he was made lord high admiral of England. He had previously been invested with the title of generalissimo of all the queen's forces. As admiral he was assisted by a council consisting of 4 members. The legality of this board was much doubted, but the parliament had such respect and veneration for the queen, that it was suffered to act without question.

GEORGE OF TREBIZOND, a learned Greek, one of the principal actors in the contest which broke out in Italy about the middle of the 15th

century between the disciples of Aristotle and those of Plato, born in the island of Orete, April 4, 1396, died in Rome in 1486. He arrived in Italy in 1480 upon invitation of Francesco Barbaro, a noble Venetian, and became professor of Greek literature and philosophy at Venice. Pope Eugenius IV. invited him to Rome in the same capacity, and made him his secretary; and he was continued in these functions by Nicholas V. Though he was famous throughout Italy, some of his hasty translations of the Greek authors into Latin drew upon him attacks from Lorenzo Valla and Theodore Gaza, and his eulogies of Aristotle and attacks upon Plato provoked the enmity of the Florentine admirers of Plato, and particularly of Cardinal Bessarion. His subsequent life was a series of disputes with the contemporary scholars, and his writings are less remarkable for philosophic insight than for violent personalities.

GEORGE, LAKE, or HORROR, a picturesque sheet of water in Warren and Washington cos., N. Y., 36 m. long, from $\frac{1}{4}$ of a m. to 4 m. wide, and in some places 400 feet deep. It is remarkable for the transparency of its water, its multitude of little islands, popularly supposed to correspond in number with the days of the year, and the beautiful scenery of its banks. Black mountain, on the E. shore, has an elevation of 2,200 feet above the surface of the lake, and 12 m. distant from it is an almost perpendicular rock rising 200 feet from the water, down which it is said Major Rogers, when pursued by Indians during the French war, slid and landed safely on the ice. Not far from this spot is the place where the English under Lord Howe landed previous to their attack on Fort Ticonderoga. The ruins of that fort can be seen at the E. end of the narrow channel through which the waters of Lake George are conveyed to Lake Champlain. Lake George was discovered by the French from Canada in 1609, and was named by them Lake St. Sacrament. Its pure waters were regularly transported to Canada to be consecrated for use in the Roman Catholic churches for baptism and other sacred purposes. The English subsequently named it after King George I. By the Indians it was called, among other names, the Horicon. It bears a conspicuous place in American history. For more than a century it was the channel of communication between Canada and the settlements on the Hudson. In the 7 years' war it was repeatedly occupied by large armies, and was the scene of several battles. On Sept. 6, 1755, occurred engagements between the French and English, near the S. end of the lake, in which Col. Williams of Massachusetts, the founder of Williams college, was killed, Baron Dieskau, the French commander, severely wounded, and the French totally defeated. In 1757 Fort William Henry, at the same end of the lake, was besieged by the French general Montcalm, at the head of 10,000 men. The garrison, after a gallant defence, capitulated, and were barbarously massacred by the Indian allies of the French. In July,

1758, the army of Gen. Abercrombie, 16,000 strong, passed up the lake in 1,000 boats, and attacked Ticonderoga without success. In July, 1759, Gen. Amherst with an almost equal force also traversed the lake and took Ticonderoga and Crown Point. The head of Lake George was the depot for the stores of the army of Gen. Burgoyne before he began his march to Saratoga.

GEORGE, SAINT, the patron saint of England, a personage whose character and very existence are surrounded with much obscurity. According to Papebroche, Heylyn, and others, he was a soldier in the army of Diocletian, and suffered death for the Christian faith. He was canonized before the 6th century, and was held in special reverence by warriors. The eastern Christians gave him the surname of the Victorious. The English crusaders brought the knowledge of him into their own country, and Edward III. made him the patron of the order of the garter, whence he came to be regarded as the tutelar saint of chivalry and the protector of England. Many writers regard him as identical with a native of either Cappadocia or Cilicia, who raised himself by flattery of the great from the meanest circumstances to be purveyor of bacon for the army. He acquired wealth by peculation, and fled from justice to Alexandria in Egypt, where he embraced Arianism, and on the expulsion of Athanasius was made patriarch of that see. His spoliations and violence so exasperated the people that they drove him from the city, and it required all the civil and military power of the province to reinstate him. On the accession of the emperor Julian he was cast into prison, whence he was forcibly taken by a mob and put to death with two of his ministers (A. D. 361). St. George is commonly represented on horseback with a dragon vanquished at his feet, this attribute probably having reference to the monster mentioned in the book of Revelation.

GEORGETOWN, an E. district of S. Carolina, bordering on the Atlantic, bounded S. W. by Santee river, and intersected by the Great Pedee, Black, and Waccamaw, which unite just above the seat of justice, and enter the ocean through the estuary called Winyaw bay; area, 818 sq. m.; pop. in 1850, 20,647, of whom 18,258 were slaves. The surface is level and partly occupied by marshes and pine forests. The soil is generally fertile, and admirably suited for rice, more of which was produced here in 1850 than in any other county or district of the United States except Beaufort, S. C. The productions that year were 46,765,040 lbs. of rice, 136,312 bushels of Indian corn, 209,800 of sweet potatoes, and 81 bales of cotton. There were 6 grist mills, 2 saw mills, 1 iron foundry, 2 newspaper offices, 26 churches, 281 pupils in academies, and 170 pupils attending public schools. Capital, Georgetown.

GEORGETOWN. I. A city and port of entry of Washington co., D. C., situated at the head of navigation on the left bank of the Potomac, 125 m. from its mouth and 2 m. W. of

Washington; pop. in 1854, about 10,000. It is separated from Washington by Rock creek, which is crossed by 2 bridges. On the N. and W. it is overlooked by heights, commanding a magnificent view of Washington and the Potomac, and a vast expanse of country, and crowned by villas and country seats, among which are the residences of some of the foreign ministers. It is a quiet, antiquated city, noted for its refined society and educational advantages. It contains several excellent hotels, and in 1850 had 2 newspaper offices, 2 banks, a market house, 7 or 8 churches, and a few mills. The most important of its literary institutions is Georgetown college, under the control of the Jesuits. Near the college is a convent of Visitation nuns, and attached to the latter a female academy, usually numbering about 100 pupils. There are several private boarding and day schools, some of which enjoy a high reputation. On the N. W. slope of the heights is the beautiful Oak Hill cemetery, thickly planted with trees and encompassed by an iron fence; it was laid out in 1849. The Alexandria branch of the Chesapeake and Ohio canal, from Alexandria, Va., to Cumberland, Md., passes through the city, and is carried across the Potomac by an aqueduct 1,446 feet long, and 86 feet above the ordinary tide. Georgetown is the only port of the district of Columbia, and its foreign commerce and coasting trade are important. (See DISTRICT OF COLUMBIA.) II. A port of entry and the capital of Georgetown district, S. C., on the W. shore of Winyaw bay, near the confluence of the Great Pedee, Black, and Waccamaw rivers, 15 m. from the sea, and 132 m. S. E. of Columbia; pop. in 1850, 1,628. The entrance to the harbor is obstructed by a bar, and this, together with the former reputation of the place for unhealthiness, for a long time checked its prosperity. Its climate, however, has improved, owing to a change in the cultivation of the neighboring rice fields. It contains the county buildings, a bank, 5 or 6 churches, an academy, several steam saw mills and turpentine distilleries, one or two newspaper offices, &c. The tonnage of the district for the year ending June 30, 1858, amounted to 1,630 registered and 76 enrolled and licensed; number of vessels entered, 11, tons 1,992; number of vessels cleared, 45, tons 8,217; value of imports, \$1,270; value of exports, \$36,174. III. The capital of Scott co., Ky., built on high ground in the midst of a fertile region on the North Elkhorn river, 17 m. E. of Frankfort; pop. in 1854, about 2,000. It contains woollen, bagging, and rope factories, and a printing office, issuing a weekly newspaper and a monthly magazine. It is the seat of Georgetown (Baptist) college, founded in 1840, occupying a building 100 feet long by 60 feet wide, and having, in 1858, 8 professors, 132 students, and a library of 7,500 vols.; of the female collegiate institute, founded in 1838, having a good chemical and philosophical apparatus, and about 100 pupils; and of the western military institute, a flourish-

ing institution which unites civil education with military discipline.

GEORGETOWN (Dutch, *Stabroek*), the capital of British Guiana and of the county of Demerara, situate on the E. bank of Demerara river, at its mouth, here about 2 m. wide; lat. $6^{\circ} 49' 24''$ N., long. $58^{\circ} 11' 30''$ W.; pop. in 1843, 23,000, of whom only 4,000 were whites; in 1851, 25,508. It is regularly built, with broad, clean streets, intersecting at right angles, and neat wooden houses having open verandas in front, thickly shaded and surrounded by gardens. Canals communicating with each other and with the river run through the middle of most of the streets, and are crossed by numerous bridges. The great business thoroughfare, in which are most of the shops and warehouses, is Water street, facing the river, and this is the only quarter inhabited exclusively by Europeans. The principal edifice is the town hall, a large, elegant stone building, with marble-paved galleries supported by cast iron columns. It contains the council hall, courts of law, custom house, treasury, and all the other public offices. The Episcopal cathedral is a handsome stone building, beside which there were in 1855 one Episcopal and 10 other churches, a great number of schools, a mariners' hospital, a colonial hospital, a lunatic asylum, botanical and astronomical societies, 2 banks, 3 newspaper offices, barracks, 2 theatres, and a market place surrounded by well-supplied shops. Below the town is Fort Frederic William, a place of little apparent strength, connected with which is a military hospital; and near it, at the mouth of the river, is an excellent lighthouse. Georgetown is unhealthy, owing to its low, marshy situation. By way of security against dampness the houses are raised on piles 3 or 4 feet above the ground. Diarrhoea, dysentery, dropsy, and yellow and intermittent fevers are prevalent diseases. There is a bar at the mouth of the river, on which there is 15 feet of water. The shipping of the port in 1853 consisted of 591 vessels with an aggregate burden of 101,764 tons. The principal exports are coffee, sugar, and rum.

GEORGIA, one of the 18 original states of the American Union, situated between lat. $30^{\circ} 21'$ and 35° N. and long. $80^{\circ} 48'$ and $85^{\circ} 40'$ W., having an extreme length N. and S. of 830 m., and an extreme breadth E. and W. of 254 m.; area, 58,000 sq. m., or 87,120,000 acres. It is bounded N. by Tennessee and North Carolina (on the 36th parallel), W. by Alabama and the Chattahoochee river, S. by Florida and St. Mary's river, E. by the Atlantic ocean, and N. E. by the Savannah river, which separates this state from S. Carolina. It is divided into 112 counties viz.: Appling, Baker, Baldwin, Bibb, Bryan, Bullock, Burke, Butts, Calhoun, Camden, Campbell, Carroll, Cass, Catoosa, Chatam, Chattooga, Chattahoochee, Cherokee, Clarke, Clay, Clinch, Cobb, Coffee, Columbia, Coweta, Crawford, Dade, Decatur, De Kalb, Dooly, Dougherty, Early, Effingham, Elbert, Emanuel, Fannin, Fayette, Floyd, Forsyth, Franklin, Fulton, Gilmer,

Glynn, Gordon, Greene, Gwinnett, Habersham, Hall, Hancock, Harris, Hart, Hayne, Heard, Henry, Houston, Irwin, Jackson, Jasper, Jefferson, Jones, Kinchafonee, Laurens, Lee, Liberty, Lincoln, Lowndes, Lumpkin, Macon, McIntosh, Madison, Marion, Mariwether, Monroe, Montgomery, Morgan, Murray, Muscogee, Newton, Oglethorpe, Paulding, Pickens, Pike, Polk, Pulaski, Putnam, Rabun, Randolph, Richmond, Scriven, Spalding, Stewart, Sumter, Talbot, Taliaferro, Tatnall, Taylor, Telfair, Thomas, Troup, Twiggs, Union, Upson, Walker, Walton, Ware, Warren, Washington, Wayne, Whitefield, Wilkes, Wilkinson, Worth.—Savannah, on the river of the same name, 18 m. from the sea, is the chief commercial and largest city of the state, and one of the principal ports for cotton, rice, and lumber on the S. E. Atlantic coast. Milledgeville, at the head of navigation of the Oconee river, is the seat of the state government. Darien, on the N. bank of the Altamaha, near its mouth; Brunswick, with a fine harbor, 20 m. further S.; and St. Mary's, on the N. bank of St. Mary's river, are other chief ports, and are largely engaged in the coasting trade. They are visited by the Florida steamships on their trips to and from Savannah and Charleston. Augusta, on the Savannah river, ranks as the second city of the state both in relation to its population and commerce; and Columbus, on the Chattahoochee, as the third. Both are frontier cities. Macon is the largest interior city. Atlanta, Griffin, Rome, &c., are also important places. Athens, Oxford, Milledgeville, Macon, and Penfield are seats of colleges. Dahlonega is the seat of a branch of the U. S. mint. —The population of Georgia in 1790 and at subsequent decennial periods, and also in 1852, was as follows:

U. S. census.	White.	Free color'd.	Slave.	Total.
1790.....	52,886	898	29,364	83,548
1800.....	101,679	1,019	59,404	162,101
1810.....	145,414	1,801	105,218	252,433
1820.....	189,564	1,767	149,656	340,987
1830.....	294,906	2,484	217,581	514,971
1840.....	407,895	2,758	280,944	691,597
1850.....	551,573	2,981	881,693	936,247
State census.	542,567	2,266	889,237	934,070

1, slaves 148. Births (white and free colored), 15,289; marriages, 4,977; deaths, 4,592; total deaths (including slaves), 9,928. Of the total population, 527,174 were under 20 years of age, 367,711 between 20 and 70, 10,826 between 70 and 100, 221 over 100, and 243 unknown. Of 595 between 90 and 100, 268 were whites, 23 free colored, and 804 slaves; and of those over 100, 55 were whites, 6 free colored, and 160 slaves. Of the total free population (524,503), there were 402,666 natives of the state, 115,418 natives of other states, 5,907 foreigners, and 517 of origin not ascertained; there were 122,954 Georgians resident in other states of the Union. Of 123,243 males (white and free colored) over 15 years of age, 20,715 were engaged in commerce, trade, manufactures, mechanic arts, and mining; 8,862 in agriculture; 11,505 in labor not agricultural; 18 in the army; 289 in sea and river navigation; 2,815 in law, medicine, and divinity; 8,942 in other pursuits requiring education; 416 in government civil service; and 178 in other pursuits. Slaveholders 88,456, viz.: holders of 1 slave, 6,554; of 1 and under 5, 11,716; of 5 and under 10, 7,701; of 10 and under 20, 6,490; of 20 and under 50, 5,056; of 50 and under 100, 764; of 100 and under 200, 147; of 200 and under 800, 22; of 800 and under 500, 4; of 500 and under 1,000, 2. Paupers supported during the year (1849-50), 1,086, costing \$27,820; criminals convicted, 80; convicts in prison (June 1, 1850), 89, all whites. Federal representative population (all free and $\frac{3}{4}$ of the slaves), 677,176, which number entitles the state to 8 representatives in the national congress.—The Savannah, the largest river of Georgia, and the boundary toward South Carolina, rises by two head streams, the Tugaloo and Keowee, in the Appalachian chain, and near the sources of the Tennessee and Hiwassee on the one side and of the Chattahoochee on the other. From the junction of these confluent at Andersonville (lat. 34° 28'), the river has a S. S. E. course of 450 m. to the sea, which it meets near lat. 32° and long. 81°. It is navigable for large ships to Savannah, 18 m., and for steamboats of 150 tons to Augusta, 280 m. further; and by means of a canal round the falls navigation for small steamboats is prolonged for 150 m. above. The Chattahoochee rises near the W. constituent of the Savannah, pursues at first a S. W. course, but at West Point (lat. 32° 52') on the Alabama line turns S. and enters Florida (lat. 30° 41') under the name of the Appalachicola. Its whole length to the gulf is about 550 m., and steamboats ascend it 850 m. to the falls at Columbus. Flint river rises in the hilly country S. of the Chattahoochee, and joins that river in the S. W. corner of the state after a course of 800 m.; it is navigable for steamboats to Albany. The Ochlockonee, Withlacoochee, and Allapaha drain the S. section of the state, and pass through Florida to the gulf of Mexico. The Withlacoochee and Allapaha by their junction in Florida form the Suwannee. Next to the Savannah, the Altamaha is the largest river

According to the tax books of 1856, there were 105,750 polls, and 416,785 slaves valued at \$210,538,634. Of the white population in 1850, there were 266,233 males and 255,839 females; of the free colored (1,408 blacks and 1,528 mulattoes), 1,875 males and 1,556 females; and of the slave (359,013 blacks and 22,669 mulattoes), 188,867 males and 192,825 females. The density of population in the same year was 15.63 to the square mile, and the proportion to the whole population of the Union 3.48 per cent. The white and free colored occupied 91,206 dwellings, and constituted 91,666 families. Deaf and dumb, 286: white 208, free colored 1, slaves 87; blind, 357: white 224, free colored 4, slaves 129; insane, 324: white 294, free colored 2, slaves 28; idiotic, 664: white 515, free colored

falling into the Atlantic. It is formed by the junction of the Oconee and Ocmulgee, which rise in the hilly region S. of the Chattahoochee and flow for about 250 m. nearly parallel to each other, when the latter bends to the E. and unites its waters with those of the former. The main river is navigable for sea-going vessels to Darien, and steamboats ascend the Ocmulgee to Macon and the Oconee to Milledgeville. The Ogeechee drains the country between the Savannah and Altamaha, and has a S. E. course of 200 m., with 80 or 40 m. of sloop navigation; its southern branch, the Cannouchee, is navigable for 50 m. The Santilla and St. Mary's drain the S. E. section of the state; both are navigable for sloops about 40 m., and for boats much further; the St. Mary's forms the boundary toward Florida. The N. and N. W. sections of the state are drained by the Tacoah, the Notley, and other tributaries of the Hiwassee; and by the Oostenaula and Etowah, which, uniting at Rome, form the Coosa, one of the tributaries of the Alabama. The Tallapoosa, also a tributary of the Alabama, has its sources in this state between the Coosa and Chattahoochee.—The coast of Georgia extends in a S. S. W. direction from Tybee sound to Cumberland sound, a distance of 128 m., with a shore line estimated at 480 m. Though generally uniform as to course, it is very irregularly indented, and is skirted by numerous low islands which extend parallel to the shores. The principal of these from N. to S. are Cabbage, Ossabaw, St. Catharine's, Sapelo, St. Simon's, Jekyll, and Cumberland. The islands as well as some tracts on the adjacent main have a light sandy soil, well adapted to the cultivation of cotton. The cotton grown here is the long staple, or, as it is called from the place of its growth, "sea-island cotton." The inlets and sounds which divide the islands from one another and from the mainland are generally navigable, but too shoal to admit vessels of more than 100 tons. Vessels of larger dimensions can enter only 4 harbors, viz: Savannah, Darien, Brunswick, and St. Mary's. The bar of the Tybee entrance of the Savannah has 19 feet water; that of the Sapelo entrance of the Altamaha, 14 feet; that of St. Simon's sound (entrance of Brunswick harbor), 17 feet; and that of St. Mary's river 14 feet. These figures represent the least water in the channel ways at low water of mean tides; the mean rise of tides on this part of the coast varies from 7 feet in the Savannah to 5.9 feet in the St. Mary's.—Georgia is naturally divided into two regions distinguished by their topography, geological structure, climate, and vegetable productions. The line of the first falls met with in ascending the streams marks here, as well as further N., the ascent upon the platform of granitic and palæozoic rocks, which stretches on to the Appalachian mountains. This line crosses the central portion of the state from Augusta on the Savannah, by Macon on the Ocmulgee, to Columbus on the Chattahoochee. It is nearly parallel with the range of the Alleghanies, that cross in a N. E. and

S. W. direction the northern portion of the state; but it is so distant from these mountains that the intervening hilly region of the metamorphic and lower silurian rocks is here much broader than elsewhere along the eastern slopes of the Alleghanies. The width of the belt is not far from 150 miles. On the S. it is succeeded immediately by the lowest tertiary, the eocene, whose sands, clays, calcareous and silicious strata, are seen reposing upon the ancient metamorphic slates and gneiss along the line of contact with these. The cretaceous formation only intervenes from a point almost in the centre of the state, near Macon, gradually widening in its outspread toward the W., and pushing the outcrop of the overlying eocene further to the S. The cretaceous group is also seen at a few isolated points rising through the tertiary near the Ogeechee river. S. of the line designated above, the whole country toward the gulf of Mexico and the Atlantic ocean is occupied by the eocene and the modern tertiaries of the coast; a belt wider even than that of the ancient formations of the N. half of the state. These two districts are often designated as upper and lower Georgia. The latter near the ocean and the Florida line is low and swampy, its better portions well adapted for the culture of rice; but these spots are uninhabitable by whites during the sickly season, whose refuge is then to the dunes, called the sand hills, that occur near the coast in parallel ranges of 40 or 50 feet elevation, or to the more salubrious climate of the "up country." The growth along the banks of the streams is of canes, cypress, *magnolia glauca* and *grandiflora*, gum of different species, including the liquidamber tree, oaks, tulip, ash, sweet bay, and many other genera; while back upon the sandy lands pines and scrub oaks are almost the only trees. Several species of palmetto give a tropical aspect to the low islands along the coast, and the magnificent live oaks largely obtained in the vicinity of Brunswick furnish the most valuable ship timber grown in the United States. In the alluvium, which attains an elevation of only a few feet above the water, skeletons of the mastodon, mylodon, megatherium, an extinct species of elephant, and of the ox, are found; and beneath the muddy peaty soil in which they lie the sands and clays are of the post-tertiary formation, containing fossil shells, all of the same species that now live in the neighboring salt water. This formation extends 20 m. inland, the surface rarely exceeding 40 feet elevation above the sea, and averaging from 10 to 12 feet. Here the land suddenly rises by a terrace 70 feet higher, and this table-land continues nearly level about 20 m. further inland, when another terrace of about 70 feet higher rise leads to a third level tract. These steps are described by Bartram in his "Travels through North and South Carolina, Georgia, &c." (London, 1792); and their occurrence is confirmed, together with many other phenomena noticed by this traveller, by Lyell in his "Second Visit to the United States." These platforms have

distinct botanical characters, the prevailing forest trees as well as the smaller plants being different in each. The upper eocene table continues to ascend toward the N., till at Milledgeville, where it meets the metamorphic gneiss, the elevation is about 575 feet above the sea. The distance to the ocean is about 200 miles. Such a surface is admirably adapted for the location of a railroad; but the soil is poor and sandy, and forests of pine cover a large portion of the country. From the central portion of the state the surface of the country becomes more elevated, the hills increase in size toward the N., and the rivers descend more swiftly as they are traced toward their sources. The southern spurs of the Appalachians are reached in the Etowah hills of Carr and Cherokee counties, and the Arnicolola hills of Gilmer and Lumpkin; and the Blue Ridge, ranging with these between Lumpkin and Habersham on the S. and Union co. on the N., constitutes the great water-shed that directs the streams on one side toward the Atlantic and on the other toward the Mississippi. In Cass co. the limestones of the lower silurian are met with just N. of the Etowah river, and the formation extends toward Tennessee, till in the N. E. corner of the state it is overlaid by later members of the paleozoic rocks, which finally are capped by the coal formation. Near the junction of the limestone with the metamorphic rocks immense deposits of iron ore are found, in the latter ranging N. E. from the S. E. corner of Cass through Cherokee. (See IRON.) Gold occurs in almost every county N. of the central line through the state, as will be noticed in the article GOLD. The copper veins worked in Polk co., Tenn., are traced across the line into Gilmer co. (See COPPER.) The other mineral productions of the state, except the limestones, and in the eocene region the marls and buhrstone of this formation, are of little importance.—The climate varies with the latitude, corresponding to that of adjoining regions in the neighboring states already described. The northern section of the state is a grain region, little or no cotton being grown in the mountain counties.—In 1850 there were in Georgia 22,821,879 acres of land occupied for farming purposes, and of this 6,878,479 acres were improved. This is about $\frac{1}{4}$ of the whole area. There were 51,759 farms and plantations, averaging 441 acres, and together valued at \$95,753,445. Value of farming implements and machinery, \$5,894,150. There were 14,573 cotton plantations, and 80 rice plantations, each raising 20,000 lbs. and over. Live stock: horses 151,831, asses and mules 57,379, milch cows 334,228, working oxen 73,286, other cattle 690,019, sheep 560,485, swine 2,168,617. Value of live stock, \$25,728,416, and of animals slaughtered in the year, \$6,839,762. Products in 1850: wheat 1,088,534 bushels, rye 58,750, oats 3,820,044, Indian corn 30,080,099, barley 11,501, buckwheat 250; potatoes, Irish, 227,379 bushels, and sweet 6,986,428; hay 23,449 tons; hops 261 lbs.; clover seed 132, and other

grass seeds 428 bushels; butter 4,640,559, and cheese 46,976 lbs.; peas and beans 1,142,011 bushels; produce of market gardens \$76,500, and orchard products \$92,176; beeswax and honey 732,514 lbs.; home-made manufactures \$1,838,968; flax seed 622 bushels; flax 5,887 lbs.; maple sugar 50 lbs.; cane sugar 446,000 lbs.; molasses 216,245 galls.; ginned cotton 499,091 bales of 400 lbs., rough 38,950,691 lbs.; tobacco 423,924 lbs.; wool 990,019 lbs.; silk cocoons 818 lbs.; wine 796 galls. Total value of agricultural products in 1840, \$29,612,436, and in 1850, \$46,686,151. Average crops (bushels) per acre: wheat 5, rye 7, corn 16, oats 18, cotton seed 500, peas and beans 5, potatoes, Irish, 125, sweet, 400. Manufacturing establishments 1,527; capital \$5,460,438; raw material \$3,404,917; hands—male 6,660, female 1,718; annual wages \$1,712,304; annual products \$7,086,525; profit 36.06 per cent. Cotton factories 35, capital \$1,736,156, cotton used 20,230 bales, products \$2,185,044. Woolen factories 3, capital \$68,000, wool used 153,816 lbs., products \$88,750. Iron works: pig 3, capital \$26,000, products \$57,800; castings 4, capital \$35,000, products \$46,200; wrought 3, capital \$9,200, products \$12,384. Distilleries and breweries 8, capital \$9,230, products 60,450 galls. whiskey and high wines. In 1810 the value of manufactured products was \$2,768,904; and in 1840, \$3,856,677. The exports from Georgia for the year ending June 30, 1858, were valued at \$9,597,559 (all domestic produce)—in American vessels \$7,958,710, and in foreign vessels \$1,638,849; and the imports at \$411,650—in American vessels \$332,740, and in foreign vessels \$78,910. Tonnage: outward, 99,156 (71,631 American and 27,525 foreign), and inward 69,993 (44,878 American and 25,615 foreign). Of the tonnage cleared, 88,050 was at Savannah, 6,476 at Brunswick, 4,680 at St. Mary's; and of that entered 66,048 at Savannah, 1,366 at Brunswick, 2,579 at St. Mary's. Shipping owned: Savannah 37,239, Brunswick 611, St. Mary's 1,745; total, 39,595 tons. Shipping built in the year, 615 tons. In 1821 Georgia exported \$6,014,810; in 1826, \$4,368,504; in 1831, \$3,959,818; in 1836, \$10,722,200; in 1841, \$8,696,513; in 1846, \$2,708,033; in 1851, \$9,159,989; in 1856, \$3,091,688; in 1857, \$10,857,634. Imports in 1821, \$1,002,684; in 1826, \$330,993; in 1831, \$399,940; in 1836, \$578,222; in 1841, \$449,007; in 1846, \$205,495; in 1851, \$721,547; in 1856, \$574,240; in 1857, \$779,909. These figures, however, do not represent the whole commerce of the state, as the great bulk of its cotton, rice, &c., is carried coastwise to the northern ports, and to a considerable extent finds an outlet through Charleston and the ports of Florida. Its imports are also chiefly coastwise.—On Jan. 1, 1858, Georgia had 33 banks and 84 branch banks, with a capital of \$10,711,190; specie, \$1,500,000; circulation, \$5,000,000.—The subjoined table exhibits the extent and cost of the railroads of Georgia as officially returned in 1858:

Names of railroads.	Terminal.	Miles.		Capital paid in.	Debt, funded and floating.	Cost of road and equipment.
		In operation.	Under construction.			
Atlanta and La Grange.....	Atlanta..... West Point.	84 1/2	..	\$1,000,000	\$196,000	\$1,171,700
Augusta and Savannah.....	Augusta..... Millen.	58	..	788,700	1,096,100
Barnesville and Thomaston.....	Barnesville..... Thomaston.	16	200,000

Western and Atlantic.....	Atlanta..... Chattanooga, Tenn.	188	..	4,495,652	90,000	5,901,497

This gives a total of 1,208 m. in operation and 218 m. under construction. To the total in operation must be added a portion (about 15 m.) of the East Tennessee and Georgia railroad, which lies within this state, and deducted therefrom 18 1/2 m. of the Western and Atlantic railroad, which extends into Tennessee. A railroad was chartered in 1857 to extend from Macon to Brunswick, 174 m., and another is projected to connect Savannah with the Florida and Cedar Keys railroad. With the exception of the Atlantic and Western, which was built at the expense of the state and passes through a rugged country, the railroads of Georgia have been constructed at a comparatively small cost, and have invariably been successful, paying from 8 to 10 per cent. annually on the capital invested in their construction. The canals of this state have been constructed for local convenience: that around the falls of the Savannah, at Augusta, is 9 m. long; another (16 m.) connects the Savannah and Ogeechee rivers, and another (12 m.) connects Brunswick and the Altamaha, making a total length of 87 m. The total length of mail route in this state on June 30, 1858, was 10,871 m., of which 1,172 m. was railroad, 1,979 m. steam navigation, 1,278 m. coach, and 5,947 m. not specified. All the chief towns are connected by telegraph. The census of 1850 presents the following statistics regarding churches:

Denominations.	Churches.	Accommodations for	Value of property.
Baptist.....	879	821,648	\$390,801
Christian.....	5	1,710	12,050
Congregational.....	1	250	2,700
Episcopalian.....	20	9,825	109,910
Free.....	6	1,780	2,650
Friends.....	2	500	400
Lutheran.....	8	2,825	84,850
Methodist.....	809	240,688	398,948
Moravian.....	1	75	25
Presbyterian.....	97	40,506	218,805
Roman Catholic.....	8	4,250	79,500
Union.....	16	7,250	21,100
Universalist.....	8	900	1,000
Minor sects.....	7	1,275	1,625
Total.....	1,892	623,992	\$1,360,859

There were 19 colleges, with 84 teachers and 1,525 students, and an annual income from endowment of \$21,720, public funds \$500, other sources \$38,210, total \$105,430; 219 academies and private schools, with 318 teachers, 9,059 pupils, and an annual income from endowment of \$7,897, public funds \$200, other sources \$101,386, total \$108,983; 1,251 public and primary schools, with 1,265 teachers, 82,705 pupils, and an annual income from endowment of \$500, taxation \$21,520, public funds \$16,959, other sources \$143,252, total \$182,231. Total number of children at school, 43,299; total number as returned by families, 77,016, of whom 42,366 were males, and 34,650 females; adults over 20 years of age unable to read and write, 41,667. There is no common school system in this state. Gov. Johnson, in his inaugural message of Nov. 1857, however, recommended a plan to the legislature. The amount of the school fund owned by this state in 1853 was \$28,086. The poor school fund is distributed among the several counties, and is paid out to teachers of schools and academies ratably, regulated by the report of the magistrates of each district. The amount appropriated by the state for 1856 was \$36,286. The following table gives the principal collegiate and professional schools, with their statistics for Jan. 1858:

Institutions.	Founded.	Instituted.	Students.	Vols. in library.
Franklin college, Athens.....	1785	10	160	18,000
Oglethorpe university, Milledgeville.....	1888	5	97	4,500
Emory college, Oxford.....	1887	6	126	1,700
Mercer university, Penfield.....	1888	8	89	7,500
Wesleyan female college, Macon.....	1889	9	150	1,800
Theological sem. of Mercer university.....	1844	2	10	2,500
Medical college of Georgia, Augusta.....	1880	7	115

In 1850 there were 51 newspapers and periodicals (5 daily, 3 tri-weekly, 37 weekly, and 6 semi-monthly), circulating 67,484 copies, or annually 1,411,976; of these, 18 were literary and miscellaneous, 6 neutral and independent, 20 political, 8 religious, and 4 scientific. The

public institutions supported by the state are the state prison at Milledgeville, and a lunatic asylum at Midway, near the capital. The state appropriates annually \$15,000 to this asylum, and the legislature of 1853 appropriated \$25,000 to enlarge and improve the buildings. The state has also an institution in Murray co. for the education of the deaf and dumb, and the blind.—The government of Georgia is based on the constitution of 1798 and amendments thereto. The right to vote is granted to every resident citizen 21 years of age, who has paid all taxes demanded for the year, and resided in the county for the 6 months preceding. Votes are given *visa voce*. The general elections are held on the 1st Monday in October biennially. The general assembly consists of a senate of 112 members and a house of representatives of 150 members, elected for 2 years. The pay of members is \$5 per diem. All revenue bills must originate in the house, and the governor's veto to any bill passed by the two houses may be nullified by a subsequent two-thirds vote. Sessions are biennial, and commence on the 1st Monday in November (odd years). The governor is elected by popular vote for 2 years, and has a salary of \$3,000 per annum. He must be 30 years of age, have been a citizen of the United States for 12 and of the state for 6 years, and be possessed of a freehold of 500 acres, or other property worth \$4,000. In case of vacancy, the office is filled by the secretary of state, and failing him, by the speaker of the house. The chief administrative officers, viz., the secretary of state, treasurer, comptroller-general, and surveyor-general, are elected for 2 years by the legislature on joint ballot, and have each \$1,600 per annum. The president of the senate and speaker of the house have each \$8 per diem. The judiciary consists of a supreme court, circuit courts, &c. The supreme court consists of 3 judges (salary \$2,500 per annum), who are elected for 6 years (one every 2 years) by the general assembly, a clerk, and a reporter. This is the highest court of appeal. Judges of circuit courts (salary \$1,800) are elected for 4 years by the people, one in each of the 16 circuits into which the state is divided. These courts have exclusive criminal and concurrent civil jurisdiction. Ordinaries or judges of probate are elected in each county, and justices of the peace in districts for 4 years. Savannah and Augusta have each a separate court of oyer and terminer, the judges of which have \$1,000 per annum.—The resources of the state treasury for the year ending Oct. 20, 1858, amounted to \$1,201,899, viz.: balance from 1857, \$437,826; earnings of W. and Atlantic railroad, \$200,000; receipts from all other sources, \$563,578. The disbursements for the same term amounted to \$745,480, viz.: on account of civil establishment, \$57,141; legislature (biennially) of 1857, \$114,242; public printing, \$20,164; lunatic asylum, building, &c., \$83,712; academy for the blind, building, &c., \$19,500; special appropriations, \$72,098; public debt, interest, &c.,

\$202,793; miscellaneous, \$175,889. The public debt consists chiefly of bonds issued for the construction of the Western and Atlantic railroad; it amounted on Oct. 20, 1858, to \$2,632,722. The semi-annual interest as well as the principal of the sterling bonds are payable in London; the interest on the remainder of the debt, nearly $\frac{1}{2}$, is payable in New York or Georgia as the holders may prefer. The debt is redeemable from 1868 to 1874. The productive property owned by the state consists of the Western and Atlantic railroad, which cost about \$5,000,000, and is estimated to be worth that sum. The state also owns productive property to the amount of \$250,000. The valuation of taxable property in 1850 was returned at \$385,116,225, in 1855 at \$528,927,963, and in 1858 at \$539,055,114.—Of the 13 provinces which declared themselves independent in 1776, Georgia was the latest settled. The country lying within its present boundaries was previous to 1733 a wilderness, and, though comprehended within the charter of Carolina, had been claimed by Spain as well as England. By patent dated June 9, 1732, George II., in honor of whom it received its name, granted the territory to a corporation entitled the "Trustees for settling the Colony of Georgia." The double purpose proposed in the settlement of this region was, on the one hand, to afford a retreat for the destitute at home, and on the other, to secure the frontiers of the Carolinas from the incursions of the Indians and the Spaniards of Florida. In November of the same year 120 persons were embarked at Gravesend under the direction of Gen. James Oglethorpe, and arrived at Charleston in Jan. 1733. From this place Oglethorpe proceeded to explore the country, and soon after purchased a large tract of land from the Creeks. On a high bluff overlooking a river the foundation of a town was laid, which received the name of Savannah. Here the settlement was commenced in the spring of 1733; but the injudicious system pursued by the trustees, and perhaps the character of the settlers themselves, impeded a rapid advance. The condition upon which the lands were parcelled out was military duty, and so grievous were the restrictions to which the colonists had to submit that many returned into Carolina, where the lands were held in fee simple. The number of inhabitants in the colony nevertheless continued to increase. In 1734 about 600 immigrants arrived out, but were principally of that class which poverty had rendered idle and dissolute. The trustees now changed their land policy, and offered 50 acres to each settler. In consequence of this regulation, the colony soon after received considerable accessions to its population, chiefly from Germany and Scotland. At this juncture, in 1739, war broke out between Spain and England, and Gen. Oglethorpe was appointed to the command of the South Carolina and Georgia troops. Having mustered 1,000 men and a number of Indian allies, he invaded Florida, but failing in an expedition

against St. Augustine, returned unsuccessful. In 1742 this invasion was retaliated, and a Spanish fleet of 86 ships and 3,000 men appeared in the Altamaha river, took Fort St. Simon, and were proceeding against Fort Frederica, on St. Simon's island, when by a stratagem conceived by Oglethorpe they became alarmed, retired to their ships, and sailed for Florida. Peace was soon after restored; but though the colony was freed from one source of disquiet, the condition of its affairs was not satisfactory. Restrictions of various kinds, and especially the prohibition of slavery, rendered the people discontented, and many abandoned their settlements, while those who remained with difficulty obtained a scanty subsistence. The complaints arising from their mismanagement at last induced the trustees to surrender their charter to the crown, and in 1752 Georgia became a royal government, with the same privileges and regulations as to land and trade and negro slaves that prevailed in the other colonies. The first good effect of the change of government was felt in the establishment of a general assembly in 1755. The limits of the colony to this time were the Savannah on the N. and the Altamaha on the S., extending westward to the Pacific. In 1763 all the lands lying between the Altamaha and St. Mary's were annexed to Georgia by a royal proclamation. From this period the colony began to make rapid progress; the rich swamps and lowlands on the rivers were brought into cultivation, and production so rapidly increased that the exports had risen from £3,059 in 1753 to £14,469 in 1763, and in 1773 they amounted to £85,891; in the same years the imports were valued at £14,128, £44,908, and £62,932. The population in 1775 was about 75,000, or more than 8 times its amount in 1752; and in this, its last year of colonial dependence, its exports were valued at £103,477, and its imports at £113,777. Thus at the commencement of the American revolution Georgia had just begun to enjoy the blessings of peace and of a more beneficent system of government. Notwithstanding these motives for continuing in connection with England, the colonists did not hesitate to make the grievances of their northern brethren their own, and take part in the coming struggle. In March, 1775, they appointed a delegate to congress; and in July of the same year a convention assembled and gave the sanction of the colony to the measures of congress. During the war that ensued Georgia was overrun by British troops, and the principal inhabitants were compelled to abandon their homes and fly into the neighboring states. In 1778 Savannah was captured, and in 1779 Augusta and Sunbury. In the latter year an unsuccessful attempt was made by the Americans and French to recapture Savannah. Georgia framed its first constitution in 1777, and a second one in 1785. The present constitution of the state is the third, having been adopted in 1798, but since that date it has undergone several amendments. The constitution of the United States was ratified by Georgia on Jan.

2, 1788. After the close of the revolutionary war Georgia suffered on her frontiers from the incursions of the Creeks and Cherokees. In 1790 and 1791 treaties were concluded with the chiefs of those nations by which the boundaries of the state were established. By the treaty of Fort Wilkinson in 1802 the Creeks ceded a large tract of land to the United States, which has since been assigned to Georgia, and now forms the S. W. counties of the state. In the same year Georgia ceded to the United States all its claims to the lands westward of its present limits, and which now form the flourishing states of Alabama and Mississippi. The subsequent intervention of Georgia in that portion of the ceded territory occupied by the Cherokees occasioned serious difficulty between the state and the national government, but was at length successful in 1838 in causing the removal of the Cherokees to the Indian territory, when Georgia came into possession of their long-coveted lands.

GEORGIA (Rus. *Grusia*; anc. *Iberia*), a country of Asia, on the S. declivity of the Caucasus, for more than 2,000 years a separate kingdom, with frequently changing governments, boundaries, and divisions, sometimes independent, and sometimes tributary to the Persians, Arabs, Tartars, &c. It was annexed to Russia in 1801, and now forms part of the Russian government of Tiflis, bounded N. by the Caucasian mountains, W. by a branch of that range, and S. and E. by Armenia and Shirvan; area, about 25,000 sq. m.; pop. about 300,000. The surface is in general mountainous, but the valleys, especially that of the river Kur, which occupies the centre of the province, are of great fertility. The climate is healthful and agreeable. The principal productions are corn, fruit, wine, hemp, flax, silk, and cotton. The inhabitants, like the other Caucasians, are distinguished for beauty of form and feature, and both sexes are highly esteemed and eagerly sought after by the Turks—the men for their armies, and the women for their harems. The sale of their serfs for these purposes long constituted the Georgian nobles' main source of revenue; but since the country passed under the sovereignty of Russia this traffic has been interdicted, and the relations between the different classes of society considerably modified and improved. The Georgians are members of the Greek church, and have had the Bible in their vernacular tongue since the beginning of the 10th century; but both priests and people are generally ignorant. Capital, Tiflis. The term Georgia is often, but incorrectly, applied to all the Trans-Caucasian possessions of Russia. Lady Sheil, in her "Glimpses of Life and Manners in Persia" (London, 1856), says of the Georgian women: "They certainly are fair, with high complexions, natural or artificial, and regular features, all of which perhaps entitle the women to the meed of beauty; still the entire absence of animation or expression deprives the countenance of attraction. They look well,

however, in their pretty dresses, while young." She further remarks: "Next to its conquerors, the Georgians are the master caste of this country. It is said that between the Georgians and the Armenians, who are found here in great numbers, there is a wonderful contrast in character and manners. The Georgian is bold, turbulent, reckless, extravagant; the Armenian is mean, cringing, timid, always intent on gain, and unlike a Georgian in keeping what he gains. It is as unsurpassable toppers, as well as for their military qualities, which have always been acknowledged, that the Georgians have acquired notoriety. At their frequent drinking parties it is said they will pass several days and nights, almost without intermission, in quaffing the productions of the vineyards of Kakheti, a district in the mountains E. of Tiflis. This wine is by no means of bad quality. It is of a deep red color, so deep that one fancies it has been tinged with some dye to produce so intense a hue. They are said to consume incredible quantities of wine on these occasions. The drinking vessel is a cow's horn of considerable length, and the point of honor is to drain it at a draught."

GEORGIA, GULF OF, an arm of the sea lying between Vancouver island and the mainland of British Columbia, between lat. 48° 50' and 50° N., and long. 122° 40' and 125° W. On the S. it is connected with the strait of Juan de Fuca, and on the N. with Queen Charlotte sound. Howe sound and Jervis and Burrard inlets run from it into the mainland. Fraser river flows into it. Its length is about 100 m., and its greatest breadth 30. At each extremity of the gulf is an archipelago of islands, and it contains several large islands, the principal of which are Texada, Savary, Harwood, and Llasqueti.

GEORGIAN LANGUAGE AND LITERATURE. The people (about 600,000) who speak the Georgian language call themselves Karthveli, but are also named Grusini, and inhabit S. and S. W. of the Caucasus, the valley of the upper and middle Kur, those of the Rion and Tchoruk, as far as the promontories of the Ararat chain, and N. E. to the Alazan, beyond which their language is mixed with the tongues of Shirvan and Daghestan, as far as the Caspian sea. Probably descendants of the Colchi and Albani, they were anciently called Iberi, and, according to tradition, are akin to the Armenians, although their language differs from the Haikanian (*Somasi* in Georgian), and is believed by their learned prince Theimuraz to be primitive. Brosset and Voss (1847) place it among the Indo-European languages. It consists of several dialects, viz.: the Karthveli or Georgian proper in the centre, the Kakheti and Imerethi next, then the Mingreli and Guri, and more remotely the Suani and the Lazi, which reaches almost to Trebizond. A colony transported into Asterabad in Persia in 1622 is said to speak a purer idiom than any of those now spoken in Georgia. The *anbangan*, or alphabet, has 3

forms, viz.: the *Khutsuri* or priestly, containing both capital and small *asgni* or letters, attributed by some to Pharnavaz, the first king, who expelled the viceroy of Alexander the Great, but more probably contrived by St. Mesrob, who made the Haikan *Aibbengim* or Armenian alphabet, during the reign of Artchil (A. D. 413-24); and the *Mkhedruli Kheli*, or soldier's hand, dating from 1812, when the Georgian calendar was reformed. The catholico or patriarch Antoni, of royal race, enriched the alphabet in his grammar (1667). It contains 8 vowels (*ā, ē, ī, ō, ū, ē, ī, ū, iū*) and 30 consonants. Of these 6 are guttural, *g, k, gh, ch, kh, h* (2); 5 labial, *b, p, f, ph, v*; 18 dental, *d, t, s, z, th, French j, sh, ds, ds, ts, dah, dah, tch*; 5 liquid, *l, m, n, r* (2). In shape it resembles the Zend letters. Beside these, about 160 contracted groups of letters are also in use. The language is very harsh and hissing, but very expressive. Its syntax has little analogy with that of other languages. Several grammatical forms are like those of the Sanscrit. It has no article and no genders. There are 8 cases of declension, viz.: nominative, ending in *i*; genitive, in *a, isa, esa*; dative, *sa*; accusative, same as the nominative; vocative, *o*; instrumental, *itha*; ablative, *sagan* (vulgarly *ida, idam*); demonstrative, *man*, with some variations. A locative case ending in *mā*, and a modal case in *d*, are also found. The plural marks, inserted between the stem and these endings, are *eb* and *n*. We give some specimens with equivalents in Latin: *puri*, panis; *khiboisa*, cancri; *uremea*, curru; *khoni*, baculum; *thavo* / o caput; *khilitha*, fructus ope (instrumental); *sakdrisagan*, a throno; *vardiman*, en rosam; *purebisagan*, a panibus; *khilebisamda*, in fructibus, &c. The pronouns are: *me*, I; *tehen*, thou; *tkhoni*, you; *teheni*, my; *ehen*, thy, &c. Numerals: 1, *erithi*; 2, *ori*; 3, *sami*; 4, *othkhi*; 5, *khuthi*; 6, *ekusi*; 7, *shvidi*; 8, *rea*; 9, *tekhra*; 10, *athi*, &c. The ordinals are the same, with *me* prefixed. There are 8 conjugations of verbs, with many variations, both by prefixes (1st person *v*, 2d and 3d *h*) and by personal endings. Many verbs have inseparable prepositions. The construction is very free, e. g.:

Radethā kbelidan rōmliṃan āknees teddāid
Whereas every-one who makes (commits) sin,
mōna ara tgi teddhiā.
serf is he sin-of.

Māmō tehenō rōmli khar tētia shna, &c.
Father our who art heaven in

—Notwithstanding the terrible devastations of Georgia by the Seljukian Osmanlis in the 11th century, by Batu Khan in 1234, by the Turks in 1552, &c., and the frequent change of masters, its princes distinguished themselves by a liberal patronage of men of letters. The dynasty of the Bagratides especially gave a great impulse in the 18th century to the development of the language, of poetry, and of the sciences. Theimuraz I., Artchil, Wakhtang VI. (who published the emperor Leo's, the Armenian, and his own laws), Sulokhan-Saba, Bakar, and many

other princes and princesses, rank among the most conspicuous Grusinian writers. The Georgian literature is mostly founded on that of Greece. The Bible was partly translated in the 8th century, finished in the 18th, and splendidly printed at Moscow, Tiflis, and St. Petersburg. Arabic and European works have also been translated into Georgian. We can mention but a few of the many remarkable national works. Among the romances are the following: *Tariel* (Of the Man in the Tiger Skin), by Skhotta of Rusthvel, a general of the heroic queen Tamar, with a commentary by King Wakhtang VI. (Tiflis, 1798); *Daredjamiani* (Deeds of Amiran, son of Daredjan, a hero of Bagdad), by the courtier Moses of Khoni; *Viramiani* (Love of the princess Vis for Prince Ramin), somewhat resembling Rousseau's *Héloïse*; *Miriani* (story of the Chinese princess Miri), imitated from the Persian. These and many others exhibit lively imagination and good taste. The *Thamariani* is a panegyric epic on Queen Tamar, by Tchakhakhadze. In poetry, there are versions of lyrical poems from the Greek, &c., by Georgi Aphoni (11th century); didactics by King Theimuraz; *Tegobil-signaoba* (Treatises by Order), by the above-mentioned catholicos and prince Antoni, a collection of historic odes; there is also a very keen satirical work by Bessarion Gabas Khoili. There are many histories of Georgia, chronicles, biographies, histories of families, monasteries, &c. The princess Makrina, about 1710, wrote a menonasticon (names of months); the last king David wrote on artillery and geography; King Irakli translated J. Sonnenfels's treatise on police, from a Persian version (Tiflis, 1782). Several princes have written accounts of their travels, as Sulkhan-Saba in Europe (1718), Bishop Jonas in Asia Minor, Venice, Austria, &c. (1789-'96), &c. The drama began to be cultivated at a late period, especially by Prince Eristov. Wakhtang VI. established a printing office at Tiflis. There are also there at present a national theatre and opera house. The *Aurora*, a periodical established in 1857, and the *Kavkas*, a Russian newspaper, are published at Tiflis.—On the Georgian language, see Stefano Paolini, *Dizionario Georgiano-Italiano* (Rome, 1629, the first Georgian book printed in Europe); Maggio, *Syntagma Linguarum Orientalium quas in Georgia Regionibus audiuntur* (Rome, 1670); Firloff, *Russo-Georgian dictionary* (St. Petersburg, 1820); J. Klaproth, *Vocabulaire et grammaire de la langue Géorgienne*, incomplete (Paris, 1827); Brosset the younger, *Éléments de la grammaire Géorgienne* (Paris, 1837); Tchubinoff, dictionary in Georgian, Russian, and French (St. Petersburg, 1840), and Russo-Georgian (Tiflis, 1857). On the literature, see J. G. Ch. Adler, *Museum Orycticum* (Rome, 1782); Alter, *Ueber Georgische Literatur* (Vienna, 1798).

GEORGIUM SIDUS, the name given by Herschel to the planet Uranus, in honor of George III., the reigning king of England when he discovered it.

GEPIDÆ, a Germanic people of Gothic origin, who first appear in history in the 8d century A. D. They came from Scandinavia, drove the Burgundians from the plains of the Vistula and Oder, occupied that region, then moved further S. and lived N. of Pannonia, between the Ostrogoths on the E. and the Visigoths on the W. Compelled to follow Attila, they became independent under their king Aderic, after the death of that conqueror, and lived on the lower banks of the Theisa, Danube, Drave, and Save, by turns as friends and enemies of the Byzantine empire. Theodoric, king of the Ostrogoths, defeated them in the battle of Sirmium (now Szerém in Slavonia) in 488. Alboin, king of the Lombards, assisted by the Avari, destroyed their power in 566.

GERA, a town and domain in the German principality of Reuss-Schleig; pop. of the former, 12,500; of the latter, with an area of 72 sq. m., 82,800. The town, situated in a beautiful valley on the right bank of the White Elster, 35 m. S. S. W. from Leipsic, consists of the town proper and two suburbs, and is regularly built, having been restored in modern style after a great conflagration in 1780. It has manufactories of woollens, cotton, linen, camlet, porcelain, stoneware, tobacco, leather, soap, musical instruments, and fire engines. It has large breweries and dyeing establishments, and carries on a considerable trade. A bank was established there in 1856. Its old castle dates from 1086, when the place first became a town, and was first bestowed on the baron of Reuss in the 12th century.

GERANIUM (Gr. *γέρωνος*, a crane), the popular name for a great many species of plants belonging to the natural order *geraniaceæ*, and divided into 4 principal genera, *erodium*, *geranium*, *Monsonia*, and *pelargonium*. The geraniums are either herbaceous or shrubby plants, exogenous, having swollen stems separable at the joints, opposite or alternate leaves, membranous stipules, and commonly symmetrical flowers, varying from those of a small size to those of remarkable proportions, beauty, and even splendor. Some are so insignificant as to be classed with weeds when fortuitously introduced in cultivated ground, while others are eagerly sought after as ornamental and attractive plants. The peculiar form of the capsules containing the seeds, which end in twisted arms resembling the beak or bill of some kinds of birds, gives the trivial name of cranesbill to the entire order, and furnishes distinctive divisions to facilitate the study of the numerous species. Thus, *erodium* is derived from *εραδός*, a heron, and comprises numerous species, mostly natives of Europe, some of northern Africa, of Asia, and America. They are either herbs or undershrubs, having variously shaped leaves and many-flowered peduncles. *E. moschatum* (musky heronsbill) is a widely distributed European plant, found at the Cape of Good Hope and in Peru, a small but handsome sort, growing in dry sandy places, and emitting a strong musky

scent. *E. cicutarium* (the hemlock-leaved heronsbill) is found indigenous in the whole of Europe, and even in the north of Africa, and, according to Don, extends to Chili. Nuttall found it common in Oregon and California, and considers it "certainly not introduced" there. It has been seen on the shores of Oneida lake, but is thought to have been adventitiously introduced. Another species, *E. macrophyllum* (Hooker and Arnott), with cordate leaves 2 to 2½ inches long, and with 8 to 5 flowered umbels, occurs in California. The annual kinds, several of which are handsome enough for the flower bed, require only to be sown in the spring in any kind of soil. The perennial species are still more ornamental, but equally ready to thrive under ordinary care. Those raised in greenhouses are most sub-shrubby, and do best in a mixture of sandy loam and leaf mould.—The genus *geranium* contains herbs, rarely sub-shrubs, having palmately lobed leaves, 1 to 2 flowered peduncles, and bearing usually beautiful flowers of various tints and hues. There are both annual and perennial kinds. Some with elegant flowers are to be met with in gardens, being of the perennial species, such as *G. collinum* (a native of Caucasus), in mountain meadows, with finely colored purplish blue petals; *G. phæum*, with dark brown petals, almost black, each having a white spot at its base. This is considered the rarest of British species, and is much admired and cultivated for its singular beauty. *G. sanguineum*, found plentifully in England, has large, beautiful crimson or blood-red flowers, which blossom most of the summer; it grows in rather dry soil. *G. anomifolium*, a species occurring at the Cape of Good Hope, is of rare beauty with its large, fern-like, glossy foliage of the most delicate green, and its rich red blossoms. *G. maculatum*, the cranesbill or crowfoot of the United States, is conspicuous in early summer in every neglected border of the fields and on the edges of the woods of New England, extending however even to South Carolina. Its large rosy-purple flowers, borne upon sub-corymbose peduncles rising above its expanded 8 to 5 parted leaves, attract the attention. As the flowers fade, the lower leaves early assume rich crimson and orange tints. This species is well suited to the garden, growing well and increasing in abundance of blossoms without any extra care. Its roots possess a fine astringency to such a degree as to be called alum root in some sections, while as a popular remedy for dysentery under the name of cranesbill it is equally sought. It is stated that large quantities of tannin and gallic acid exist in it. Two other perennial species, *G. orianthum* of the N. W. coast, and *G. albidiflorum* in the valleys of the Rocky mountains, are allied to it; the latter with white flowers as its name implies, the former with large purple blossoms, the bases of whose petals and stamens are densely villous. Of the annual kinds we have *G. Robertsonianum*, or herb Robert, a beautiful plant common in our

woods, especially among rocks and in the rich black mould of their crevices, where they are partially shaded. Its flowers, though small, are numerous and prettily striped and rosy, and its foliage so delicately cut and borne upon long slender petioles, that it is well adapted for the garden, especially in the rockwork. A heavy disagreeable odor is however emitted from its leaves, if slightly touched or carelessly handled. Frequently in the autumn the leaves are curiously dotted with minute black specks, the perithecia of a parasitic fungus (*dothidea Robertsonianum*). *G. Carolinianum*, similar, with paler flowers and scentless foliage, erroneously supposed to be *G. dissectum*, occurs in waste places on barren soils, and is widely diffused. *G. pusillum* (small-flowered cranesbill), with slender stems, rounded, 5-parted, kidney-formed leaves, and small bluish-purple petals, has been found in waste places in New York and Boston, although a European species.—In honor of Lady Ann Monson, who introduced into Great Britain many curious plants from India, and who was distinguished for her botanical acquisitions, we have the genus *Monsonia*, remarkable among the *geraniaceae* for its large, showy, and even splendid flowers, consisting of a calyx of 5 equal sepals, and 5 equal petals twice the size of the calyx; all perennial plants, with toothed, lobed, or decompound leaves. Considerable diversity in the form of foliage, and in the entire or divided edges of the petals, is to be found among the species. They are all natives of the Cape of Good Hope. Mr. Don affirms that the entire genus consists of very showy herbs, deserving to be cultivated in every greenhouse. Their favorite soil, according to Sweet, is a mixture of light turfy loam and decayed leaves. They are easily increased by cuttings or by pieces of the roots, using the hand glass to facilitate the operation. *M. speciosa* is a showy flower, and *M. lobata* has very beautiful unexpanded buds, more showy than the rosy corollas, requiring the bright rays of the sun to bring them to perfection.—The genus *pelargonium* derives its name from Gr. *πτελαργος*, a stork, and the storksbill geraniums are those best known in indoor culture. With the exception of a very few, the species, exceedingly numerous, are natives of the Cape of Good Hope. Indeed, so vast in number are the kinds, that artificial distinctions are invented in order to arrange them. Of these, the most curious as well as prominent are of the sections of the stemless and tuberous-rooted, which have all their leaves near the base of the plant or just above the summit of the root. The leaves vary greatly in form, being either oblong and entire, or lobed with the lobes entire, or hardly toothed, or cordate-sagittate with 8 lobes, or pinnate with the leaflets cut and even multifid. The flowers are supported on long peduncles, are of moderate size, but frequently of rarest beauty, and in the hybrid sorts the colors are of the richest tones. There are some whose flowers are dingy or yellowish, but which com-

pensate for want of beauty by emitting a powerful fragrance on the approach of evening. *P. apiifolium* (celery-leaved storkbill) and *P. vespertinum*, a hybrid variety, may be cited as instances. There are also the sad or thistle-flowered, having pale greenish yellow blossoms, but at dusk uniformly very fragrant. A section called *fulgida* exhibits kinds with flowers of the greatest splendor, with intense purple or scarlet colors, such as *P. sanguineum*. From these stemless and herbaceous though perennial species, we can trace gradations in others whose stems are flexible and inclined to climb, with fleshy, peltate, and 5 lobed leaves, few-flowered umbels, and pale purple blossoms; considered desirable on account of their clean, lustrous foliage, emitting on being bruised a pleasant scent, admirably fitted for baskets as hanging plants, or to be trained on small wire trellises in pot culture. Of these the most familiar is *P. peltatum* (peltate storkbill), a universal favorite, blooming very freely when kept rather dry, but producing glossy and large leaves in cool and moist situations. A variety with variegated leaves is known. A beautiful white-blossomed species of similar habits is the *P. scutatum*. Through such half woody-stemmed species we reach the fleshy and shrubby kinds in the group of *ciconia*, embracing those whose stems are tall, the umbels producing a profusion of blossoms of some single color, such as *P. zonale* or horse-shoe geranium, so called from a dark discolored semicircular line on the disk of the rounded, crenate leaf. The flowers of this species are borne in large showy heads, supported on very long peduncles; they are scarlet or red, rose, pale, or white. A distinct variety is *P. martinatum*, where the leaves cease to be zonate, and have instead a white or yellowish margin, and known as the silver-leaved geraniums. Some of the choicest hybrids for ornament are found here, possessing fanciful names to distinguish them from each other, either as dwarf sorts, or kinds of prostrate habit, or for some peculiar color of the petals. Such sorts are bedded out in borders or on lawns, producing a unique or gorgeous effect from the profusion and brilliancy of their bloom. These low and prostrate kinds are extreme aberrations from the usual attitude. Another species, *P. inquinans*, has bright crimson or scarlet flowers, and the foliage on being bruised by the hand leaves behind a stain of a brownish color. The hybrid from it, called *P. Bentinckianum*, is described with flowers of the intensest scarlet. This is a tall-growing sort, attaining a height of 4 feet. A writer in London's "Gardener's Magazine" (vol. vii. p. 677) speaks of a seedling of the variety called Waterloo, which had a stem 5 feet 10 inches high, and measured at 5 feet from the ground 5½ inches in circumference. It is stated on good authority that when trained to stakes or otherwise supported, the species belonging to the *ciconia* will grow 8 or 10 feet high. One which came within our own observation, trained on the back wall of a green-

house, considerably exceeded that height, and the woody stem near the base of the plant furnished a tolerably stout and stiff walking stick. The succulent fleshy habits of these species adapt them to endure long continued droughts without seriously endangering their vitality; and when kept dry in sand and free from frost, they can be easily preserved through the winters and planted out for successive summers. Taking a hint from this fact, Mr. Loudon advises, in his *Arboretum Britannicum*, the trial of some sorts, by planting them at the foot of warm walls, covering the roots on approach of frost with litter so deep as to exclude cold and moisture, and thus acclimating them; an experiment, even in the hardest wooded sorts, better adapted to England than to our climate. With more suffruticose stems, still rising to considerable heights, we find the most magnificent flowers among those series which comprise those with unequal-sized petals, the 2 upper ones being broader and longer, and the 8 lower being narrow. In these, the colors vary from pure white and rosy to purple and the deepest crimson. In *P. cordatum* (heart-shaped storkbill) the upper petals are very much broader than the lower, which are indeed scarcely more than linear. In *P. betulinum* (birch-leaved storkbill) the upper petals are beautifully pencilled with crimson streaks. Among the purple sorts is *P. cucullatum* (hood-leaved storkbill), in which the upper petals are of a rich purplish red, but marked with darker purplish streaks. In *P. ternatum* the foliage is deeply cut and the lobes sharply serrated, but the markings on the upper petals are reduced to a few shortened and thick lines. From the nearly entire-edged foliage of the first mentioned, we notice by similar gradations those whose leaves are deeply parted into segments and lobes, as *P. quercifolium* (oak-leaved storkbill); and in *P. radula* (rasp-leaved stork's bill) we notice a palmated leaf with narrow and pinnatifid lobes; while others of the hybrid sorts are carried to still minuter divisions. Such a variety of forms in the contour and outline of the foliage would be enough, independent of the richness of the blossoms, to entitle this order to regard. The pelargoniums all mix freely, and hybridization is easily effected. By this process the most bizarre and the most magnificent varieties are produced. To such extent is this carried, that what are called prize flowers seem scarcely related to the original species, so much are the petals increased in size, in depth of color, and in equality of the lower petals with the upper. In some the face of the blossom assumes nearly a circular outline, while in others art has produced irregularity nearly monstrous in the jagged edges, in the strange contrast of tints, and in the tendency to become double; such sorts are pronounced fancy blooms. When hybridization is to be performed, the flowers of the plant to be artificially impregnated are early deprived of their stamens before the anthers burst, care being taken not to injure the stigma. The

farina or pollen is selected from the richest and choicest kinds, it being admitted that the offspring follow more nearly the character of the male parent. The capsule soon swells and ripens, when the seeds are sown, and a few months' patience is rewarded by new and perhaps choicer hybrids. Scarcely any other plants are propagated so easily, and pieces of the young stems, cut across just below the joint and planted in sandy soil, root freely, especially if stimulated by gentle heat. Slips from the roots will send out buds and make new plants by similar treatment. Some of the dwarf woody-stemmed kinds have been grafted; and *P. tricolor*, when worked upon the summit of a taller variety, exhibits a charming effect from its sea-green foliage and brilliant flowers of black, red, and white. Light and plenty of air, with occasional sponging of the leaves to remove dust from their surface, and with moderate heat, are the chief requisites in parlor culture; but on the appearance of the buds an increase of water should be given. In their growing condition slight watering is found best, as too great a quantity causes the plant to grow weak and run to leaves. A splendidly illustrated work on the species and varieties of pelargoniums was published in London between the years 1830 and 1880 by Robert Sweet; but the demand for the newer sorts caused these now almost obsolete kinds to be lost, and the distinct and original species it records furnish the chief value of the book. In London's "Encyclopædia of Gardening" (2d ed., 1834) may be found a list of the finest hybrids extant at that time; while the catalogues of every year enumerate hundreds of the latest, which fashion or fancy has produced at home or abroad. To reduce these to their specific position, and to discover their parentage and ancestry, would prove as difficult a task as the result would be curious and gratifying. Those cited in this article are mostly distinctive species, originally brought from the Cape of Good Hope, and seldom seen now except in the collections of the botanist.—The *geraniaceæ* furnish little of utility to man, unless as commercial articles of an ornamental kind in the florists' trade; though *P. antidysentericum* is used among the Namaquas as a remedy for diarrhoea, the roots of *P. triste* are eaten at the Cape, and in Van Diemen's Land the native carrot is the root of *G. parviflorum*, while an astringent principle is characteristic of the order.

GERANDO. I. JOSEPH MARIE DE, baron, a French philosopher and statesman, born in Lyons, Feb. 29, 1772, died in Paris, Nov. 10, 1842. The son of an architect, he was educated in the college of the *oratoire* at Lyons, and was preparing for the priesthood against the wishes of his family when the revolutionary persecutions of ecclesiastics led him to change his purpose. When in 1793 his native town was besieged by the troops of the convention, he took arms for its defence, distinguished himself for bravery, was made prisoner, and narrowly escaped death. Obligated to flee for safety, he

went to Switzerland and thence to Italy, and was employed 2 years in a commercial house in Naples. He returned to France after the proclamation of an amnesty to the Lyonnese emigrants, and in 1797 was persuaded to go to Paris by his relative and former schoolmaster, Camille Jordan, who had been appointed a member of the council of 500. On the 18th Fructidor he succeeded in saving the life of his relative, whom he accompanied in his flight to Germany. He then joined a regiment of cavalry in the French army, and was in garrison at Colmar when the French institute proposed the question: "What is the influence of signs on the formation of ideas?" De Gerando hastily wrote a dissertation on it, and learned that he had received the prize soon after the battle of Zürich, in which he had taken part. Invited to Paris, he entered the ministry of the interior under Lucien Bonaparte in 1799, became secretary-general of that department under Champagny in 1804, accompanied him to Italy in 1805, was appointed master of requests in 1808, was afterward engaged in the organization of Tuscany and of the Papal States when they were united to France, received the title of councillor of state in 1811, and was called to the difficult office of governor of Catalonia in 1812. On the fall of the empire he retained the dignities of councillor of state, baron, and officer of the legion of honor, to which he had been raised by Napoleon; but for having been sent to organize the defence of the Moselle during the Hundred Days he was at first discarded after the second restoration, but soon resumed his place in the council of state, which he held during the rest of his life. In 1819 he began a course of lectures before the faculty of law in Paris on public and administrative law, which were suspended in 1822, and resumed under the Martignac ministry in 1828. In 1837 he was raised to the peerage. Though distinguished for his discretion and ability as an administrative officer, and for his zeal in promoting national industry, useful discoveries, and charitable associations, he is remembered chiefly for his philosophical writings. In the leisure which he enjoyed after his dissertation was crowned by the institute, he enlarged it, and published it under the title *Des signes et de l'art de penser considérés dans leurs rapports mutuels* (4 vols. 8vo., Paris, 1800). His other principal philosophical works, in which he follows with some deviations the school of Condillac, are the treatise *De la génération des connaissances humaines* (Berlin, 1802), and the *Histoire comparée des systèmes de philosophie* (3 vols. 8vo., Paris, 1808), a posthumous addition to which appeared in the 3d edition (1847-'8). The latter is much superior to any French work on the history of philosophy that had preceded it. In 1825 he received the prize of the academy for his treatise *Du perfectionnement moral et de l'éducation de soi-même* (translated into English, Boston, 1830), the fundamental idea of which is that life is a discipline whose object is perfec-

tion. The 5 leading motives which solicit the will are sensations, affections, thought, duty, and religion; and the two conditions of harmonious development are a love of goodness (*l'amour du bien*) and a habit of self-control. His *Visateur du pauvre* also received the prize of the academy (1821). In 1827 he published a work in 2 vols., entitled *De l'éducation des sourds-muets de naissance*. His *éloge* was pronounced by Beugnot and Bayle-Mouillard.

II. AUGUSTE DE, nephew of the preceding, a French traveller and author, born in Lyons, April 4, 1809, died in Dresden, Dec. 8, 1849. After completing his collegiate course he began to study law in accordance with the advice of his uncle, who was also his guardian. In his 21st year he met the young countess Emma Teleki of Hungary, and, prevailing over the objections both of her friends and his own, was married to her at Paris in 1830. He immediately departed with his wife through Austria and Hungary to Hosszufalva in the northern part of Transylvania, the residence of her father, Count Emeric Teleki. For several years he was occupied in studying the social and political characteristics of Transylvania and Hungary, and early determined to awaken the sympathy of liberal minds in the west of Europe for the men who were seeking the development of the institutions and the extension of the liberties of those countries. He visited France in 1840, but returned to Transylvania in time to witness the assembling of the diet in 1841, and in 1844 published in Paris an "Essay on the Origin of the Hungarians," tracing them in accordance with their own traditions to the Huns. In the following year appeared his "Transylvania and its Inhabitants," which had a wide circulation in Europe, and treats fully of the population, antiquities, and history of the country, and especially of the efforts of the Hungarians for national independence. In 1845 he again left France for Hungary, and resided at Hosszufalva and Pesth till in 1848 he published a work entitled *De l'esprit public en Hongrie depuis la révolution Française*, containing an elaborate sketch of the political history of Hungary from 1790 to the assembling of the diet in Nov. 1847. It appeared in French, German, and Hungarian. He returned to Paris on hearing the news of the French revolution of 1848, and contributed numerous articles to the *National* newspaper, giving exact information on Hungarian and Austrian affairs. His health failing, he retired to Nancy, but returned to Paris in May, 1849, and published in the *National* a series of essays entitled *Les steppes de Hongrie*. He left France in July for Hungary, and was on his way to join Dembinski, intending to write a history of the campaign, when he heard of the surrender of Gorgey, and escaped into northern Germany. He did not recover from the shock occasioned by the fall of Hungary, and, unable to undertake the journey to France, was joined by his wife and other friends at Dresden a few weeks before his death.

Michelet offered a tribute to his memory as "the author of two works, in one of which he unveiled an oriental world before unknown to us, and in the second proved that those distant people were not wholly foreign to us, that in political sympathy they were ourselves;" and as, by his connection with the Parisian press, "disputing the ground, inch by inch, with the falsehoods of absolutist Europe."

GÉRARD, CÉCILE JULES BASILE, a French officer, called the lion-killer, born in Pignans, Var, June 14, 1817. Enlisting in the Spahis, he landed in Africa in 1842, and 2 years later killed his first lion. He took a fancy for the sport, in which he has evinced extraordinary tact and courage, and in 1855 had killed no fewer than 25 lions. He has given the results of his experience in 2 books: *La chasse au lion* (1855, 2d ed. 1856), and *Gérard le tueur de lions*, written under a pseudonyme (3d ed. 1858). The latter has been translated into English (New York, 1857).

GÉRARD, ÉTIENNE MAURICE, count, a marshal of France, born in Damvilliers, Meuse, April 4, 1773, died in Paris, April 17, 1852. The son of a notary, he enlisted in 1791 as a private soldier, served under Dumouriez and Jourdan, distinguished himself in the battles of Fleurus (1794), Kreuznach (1795), and Teining (1796), and as aide-de-camp of Bernadotte at Vienna, and obtained a colonelcy in 1800. He signalized himself at Ansterlitz, Halle, Jena, and Wagram, receiving as reward for his services the rank of general of brigade and a barony. After service in Portugal and Spain, he joined the Russian expedition, gave new proofs of valor and talent, and as general of division evinced unflinching energy during the retreat from Moscow. He was severely wounded in the campaign of 1813, and in 1814 fought successfully against the invading troops at Dienville, Montereau, and Méry. During the campaign of 1815 he was placed under the command of Marshal Grouchy, who had orders from Napoleon to prevent the Prussians from joining the English army under Wellington. On the morning of June 18, hearing the report of cannon, he strongly urged a march toward Waterloo, but was overruled. Had his advice prevailed, the issue of the battle might have been changed. On the fall of Napoleon, Gérard left France, and did not return till 1817. In 1823 he was elected deputy, and took his seat among the opposition members. He contributed to the success of the revolution of 1830, and after being minister of war for 8 months, reentered the chamber of deputies, was promoted to the rank of marshal, April 17, 1831, and was intrusted with the command of the French army sent to protect Belgium against Holland. He commanded at the celebrated siege of Antwerp, which he forced to capitulate, Dec. 23, 1832. In 1834 he again held for 3 months the office of minister of war. He was made count in 1813, peer in 1832, grand chancellor of the legion of honor in 1835, and senator in 1852.

GERARD, FRANÇOIS PASCAL SIMON, baron, a French painter, born in Rome in 1770, died in Paris, Jan. 11, 1837. He entered the studio of David in 1786; in 1792 he visited Italy, but soon returned, and exhibited in 1795 his first great picture, "Belisarius," which was received with marked favor. "The Three Ages," "Cupid and Psyche," "Ossian," and the "Battle of Austerlitz," which appeared in succession from 1806 to 1810, established his fame. The last was applauded for its accuracy and beauty by the emperor, who, as well as nearly all the members of his family, had their portraits painted by Gérard. The return of the Bourbons did not diminish his success. At the command of Louis XVIII. he executed in 1817 his "Entry of Henry IV. into Paris." In 1819, at the request of Prince Frederic Augustus of Prussia, he painted his "Corinne at Cape Miseno," a beautiful scene from Mme. de Staël's novel. His "Louis XIV. declaring his Grandson Philip of Anjou King of Spain" appeared in the public exhibition of 1828; and his "Coronation of Charles X." in that of 1829. Under Louis Philippe he executed various important works in the halls of the historical museum at Versailles and in the cupola of the Pantheon. The latter, completed in 1836, were the last of his performances. During his career, beside 80 historical pictures, some of which are of very large dimensions, he painted nearly 300 portraits.—His nephew, HENRI GÉRARD, has published a collection of his works, with a notice and explanations (3 vols. folio, Paris, 1852), and is also preparing the correspondence and MSS. of his uncle for publication.

GERARD DE NERVAL (GÉRAUD LAURENCE), a French author, born in Paris, May 21, 1803, died there, Jan. 24, 1855. He published, when 18 years old, a series of poems, entitled *Élégies nationales*, and in 1828 a new translation of *Rust*, which, according to Goethe himself, was a marvellous piece of ingenuity. He soon became a contributor to periodicals, tried his hand at the drama, and wrote pieces of various kinds, either by himself or in conjunction with Alexandre Dumas. One of the latter, *Leo Burckart*, was published in 1839 with notes. About 1840, on the death of the actress Jenny Colon, whom he devotedly loved, he took to travelling, and published narratives of journeys through Italy, Germany, Belgium, Holland, Greece, and the East. On his return to Paris in 1844, he was for a while the substitute of Théophile Gautier as *feuilletoniste* of the *Presse*. In 1850, in conjunction with Méry, he produced, under the title of *Le chariot d'enfant*, a metrical translation of an Indian drama. He then undertook a series of philosophical and biographical essays upon eccentric characters, which he collected under the title of *Les illuminés, ou les précurseurs du socialisme* (1852). The erratic mode of life, solitary meditations, and sad remembrances of Gérard had caused a mental disease, which, though apparent in most of his actions, did not interfere with his literary productions, and perhaps added a charm to them. On the

morning following the anniversary of the death of Jenny Colon, he was found hanged and dead in one of the foulest streets of Paris.

GERASA, or GALASA (now *Jerash*), a ruined city of Syria, in ancient Decapolis, 80 m. S. S. W. of Damascus, situated on the opposite slopes of 2 hills, between which flows the river Keruan. The most interesting of its magnificent remains extend along the right bank of the stream, and comprise a Corinthian temple and triumphal arch, 5 or 6 other temples, and 2 theatres, all of marble; a naumachia, or artificial basin for the representation of sea-fights, and a small temple, with a semicircular Ionic colonnade from which a street, lined with rows of columns; traverses the city. At right angles with this are 3 other streets, all full of relics of ancient greatness. There are raised walks for foot passengers on either side, while the centre course still shows marks of chariot wheels. The walls, which are pierced by 3 ornamented gateways, and flanked by occasional towers, are in tolerable preservation. Outside is an extensive necropolis; 200 yards N. E. is a large reservoir, and near it can be traced an aqueduct. The river and valley are crossed by 2 bridges. There are 2 grand baths, and inscriptions, chiefly of the time of Antoninus Pius, but in general much defaced, are met with in all directions. The ruins are reported by Irby and Mangles to be much finer than those of Palmyra. The city was built by the Romans after their eastern conquests, was burned by the Jews to avenge the massacre of their Cæsarean brethren by the Syrians, taken and again burned by Annus, one of Vespasian's generals, and in 1122 captured by Baldwin II. of Jerusalem, who destroyed its castle.

GERHARD, EDUARD, a German archæologist, born in Posen, Nov. 29, 1795. He was educated at Breslau and Berlin, studying under Heindorf, Schneider, and Böckh. Resigning a professorship on account of weak eyes, he travelled in Italy, and resided 15 years in Rome. He was engaged on Platner's "Description of Rome," planned by Niebuhr, and then directed by Bunsen, for which he undertook to furnish a complete account of the sources of knowledge concerning ancient Roman topography, under the title of *Scriptores de Regionibus Urbis*. This task, however, was not completed. In order to unite all the departments and details of antiquarian knowledge, he proposed the establishment of archæological societies, and a systematic correspondence between them, and reproduction by engravings and descriptions of all known antiques. When in 1828 the crown prince of Prussia visited Italy, Gerhard accompanied him to Naples, and obtained his protection for an archæological society, the *Instituto di corrispondenza archeologica*, founded at Rome, among the members of which were Bunsen, Panofka, the duke of Luynes, Millingen, and Gerhard, who directed it till his return to Prussia in 1837. He was afterward appointed archæologist of the royal museum at Berlin, professor in

the university of that city, and member of the academy of sciences. Among his numerous writings are *Antike Bildwerke* (Stuttgart, 1827-'44, with 140 copperplate illustrations); *Auserlesene Griechische Vasenbilder* (3 vols., Berlin, 1839-'47, not yet completed, with 240 plates); *Griechische und Etruskische Trinkschalen* (1848); *Etruskische und Campanische Vasenbilder* (1843); *Trinkschalen und Gefäße* (1848-'50); *Ueber die Hermentbilder auf Griechischen Vasen* (1856); and a large number of monographs and contributions to periodicals.

GERHARDT, CHARLES FRÉDÉRIC, a French chemist, born in Strasbourg, Aug. 21, 1816, died there, Aug. 19, 1856. The son of a manufacturer of chemical products, his studies were naturally directed to the science connected with the profession of his father. He was in 1831 and 1832 a member of the polytechnic school at Carlsruhe, and afterward attended Erdmann's course of lectures at Leipsic. In 1835 he pursued his scientific studies in Liebig's laboratory at Giessen, and in 1838 removed to Paris, where he devoted himself to chemical investigations. In 1844 he was appointed professor at Montpellier, where he remained 4 years. His most important publication during this period was one upon the essential oils. From Montpellier he returned to Paris and established a private laboratory, in which he continued his researches till 1855, publishing during this time his original papers upon homologous series, the theory of types, the anhydrous acids, and the starches. In 1855 he accepted the chair of chemistry and pharmacy at Strasbourg, which he lived to occupy only one year. His studies were chiefly in the field of organic chemistry, and were in great part directed to the establishment of a correct system of classification of the numerous compound bodies belonging to this department. He introduced simple methods of grouping results so that they should most readily lead to new discoveries, and present classes of phenomena in a clear connection to the mind, and consequently in a form to be most easily retained. He regarded chemical formulæ not as presenting a fixed absolute value, but rather the equivalent compositions of bodies, an idea first advanced by Chevreul. Among Gerhardt's most important publications is the *Traité de chimie organique* (4 vols. 8vo., 1854-'6), upon which he was occupied a large portion of his life, and in which he presents a complete account of the actual progress of organic chemistry together with his own peculiar views. The work was intended as an appendix to Berzelius's *Chimie minérale*. He also published translations of some of Liebig's works, beside other treatises of his own.

GERHARDT, PAUL, a German poet and theologian, born in Gräfenhainichen, Saxony, March 12, 1807, died in Lübben, June 7, 1876. Little is known of his life till in 1851 he became pastor at Mittenwalde, a position which he exchanged in 1857 for that of deacon in the church of St. Nicholas, in Berlin. He was there a partisan of the strict Lutherans against

the syncretism of Calixtus and his followers, and was deprived of his diaconate because he refused to obey the edict of 1664 forbidding either party to defame the other in the pulpit or tax it with heresy. In 1668 he became archdeacon in Lübben. He is esteemed the author of the best German hymns after those of Luther; several of them were translated by John Wesley, and are found, in part at least, in the Methodist hymn book. In Germany they were first collected under the title of *Geistliche Andachten in 120 Liedern* (Berlin, 1666; 4th ed. 1688), and many of them are contained in most of the Protestant hymn books in Germany. Of their numerous editions, the last is that of Wackernagel (Stuttgart, 1849).—See C. A. Wildenhahn, *Paul Gerhardt, ein kirchengeschichtliches Lebensbild* (Leipsic, 1845; 2d ed. 1850).

GÉRIOULT, JEAN LOUIS THÉODORE ANDRÉ, a French painter, born in Rouen in 1790, died in Paris, Jan. 18, 1824. He was a pupil of Carle Vernet, and of Guérin, and his first pictures attracted little attention. In 1816 he went to Italy, and in 1819, on his return to France, he exhibited the "Raft of the Medusa," a most dramatic scene, executed in the most powerful style, which was enthusiastically received, and is still considered one of the masterpieces of the French school.

GERLACH, ERNST LUDWIG VON, a Prussian statesman, born in Berlin, March 7, 1795. After the war of liberation (from 1813 to 1815), in which he had taken part with his brothers Leopold and Wilhelm, he joined in Berlin a celebrated club, where a circle of highly gifted men discussed the political and ecclesiastical regeneration of Prussia, thus forming a nucleus for the high church aristocratic party, of which Gerlach has been for many years the leader. After having been in succession councillor, director, and president of divers Prussian courts, he was employed from 1842 to 1844 in the ministry of justice in preparing new propositions for the legislation on marriage, and became in 1844 a member of the state council. From 1849 to 1858 he was a member of the Prussian upper chamber and a leader of the extreme conservative party. At the new elections in 1858 he was defeated, in a district which was considered one of the strongholds of the party. From 1831 to 1837 he was a contributor to the *Politisches Wochenblatt*, and afterward one of the founders of the "New Prussian Gazette," for which he wrote monthly articles called *Rundschau*, many of which were also published separately.

GERLAOHE, ÉTIENNE CONSTANTIN DE, baron, a Belgian statesman, born in Biourge, in Luxembourg, in 1785. He began to practise law at Liège in 1815, was appointed a councillor in the court of appeals, and from 1824 to 1830 was a prominent member of the second chamber of the states-general, where he especially endeavored to keep the union of the Catholic and liberal opposition within the limits of law. After the outbreak of the Belgian revolution in 1830,

he induced the Belgian deputies to attend the extraordinary session of the states-general which had been convoked at the Hague. Having returned to Belgium in consequence of the events in Brussels, he became a member of the committee charged with drafting a new constitution, and was elected a member, and, a little later, president of the congress. In this capacity he headed the deputation which offered the crown to Prince Leopold of Saxe-Coburg, to whom he afterward, as president of the chamber of representatives, administered the oath on the constitution. In 1832, at the reorganization of the courts of justice, he was made president of the court of cassation. In 1839 he accepted a mission to the conference of London to make proposals for the settlement of the territorial differences with Holland. He is a prominent leader of the Catholic party in Belgium. His principal work is *Histoire du royaume des Pays-Bas depuis 1814 jusqu'en 1830* (2d and enlarged edition, Brussels, 1842).

GERMAN CATHOLICS (*Deutschkatholiken*), the name of a religious denomination, formed in 1844 by secession from the Roman Catholic church of Germany. It owed its origin mainly to a letter, written Oct. 1, 1844, by Johannes Ronge, an excommunicated priest of Silesia, to Bishop Arnoldi of Treves, in which the exhibition of the holy coat of Treves was called an idolatrous festival, and the bishop was called upon to suppress it. In the Prussian province of Posen another Catholic priest, Johann Czerski, had already declared on Aug. 22 his secession from the Roman Catholic church, and had attempted the foundation of a Christian apostolic Catholic congregation. After the publication of the letter of Ronge these two united, and a number of congregations, who called themselves German Catholics, sprang up within a short time. The "Confession of Schneidemühl," drawn up by Czerski Oct. 19, and presented to the government Oct. 27, rejected as unscriptural, and as merely human ordinances, the reception by the priests alone of the Lord's supper in both kinds, the canonization and invocation of the saints, indulgences and purgatory, fasting, the use of the Latin language in divine service, mass, and vespers; the celibacy of priests, the prohibition of mixed marriages, the supremacy of the pope, and other points. They declared themselves determined to sever their connection with the pope, to receive the Lord's supper in both kinds, and to recognize the Bible as the only rule of faith. They retained the 7 sacraments and the mass, which they celebrated in the vernacular language. The "Confession of Breslau," which set forth the views of Ronge, not only rejected the same ordinances as that of Schneidemühl, but claimed free investigation of the Bible and freedom of belief for every individual member. It admitted as essential doctrines only the belief in God, the creator and ruler of the world; in Jesus Christ, who, by his doctrine, his life, and his death, redeemed men from servitude and

sin; and in the influence of a Holy Spirit upon earth. Of the sacraments of the Catholic church it retained only baptism and the Lord's supper. A council which met at Leipsic, March 22, 1845, and in which Ronge, Czerski, and the delegates of 20 congregations took part, adopted (March 26) a new creed, mostly based on the "Confession of Breslau." From this time the principles of German Catholicism spread very rapidly. In Silesia alone the number of German Catholics was estimated in June, 1845, at nearly 50,000; and toward the end of that year the number of congregations in Germany rose to 298. Not only many Catholic priests and professors, as Dr. Theiner and Dr. Regensbrecht of Breslau, and Dr. Schreiber of Freiburg, joined the movement, but also many Protestant clergymen. The attitude of the governments with regard to German Catholicism was very diverse. In Austria and Bavaria it was even forbidden to use the name; in Prussia the question whether they ought to be counted among the tolerated denominations was not definitely decided, but provisional decrees were published concerning their baptisms, burials, and marriages. Great rigor was employed against them by the governments of Baden and the electorate of Hesse, while majorities of nearly all the legislative assemblies declared their sympathy with them. A more serious obstacle to the growth of the new religious denomination than the disfavor of the governments was found in their internal dissensions. There had been from the beginning a radical disagreement between Ronge and Czerski. The latter agreed in general with the doctrines of orthodox Protestantism, while the former adopted almost all the views of the Protestant rationalists. Czerski issued a circular ("New Confession of Schneidemühl") against those who denied the divinity of Jesus Christ. An attempt to unite both parties on a common platform was made in an assembly at Rawicz, Feb. 8, 1846, in which Ronge, Czerski, and Theiner took part; but it had not the desired effect. The congregations sympathizing with Czerski held a meeting at Schneidemühl, July 22-24, 1846, but were not able to effect a closer organization, as they themselves differed among themselves on many points. Among the congregations which followed Ronge there was also a great deal of dissension, so that the interest in German Catholicism began to decrease in 1847. The council of Berlin, held in May, 1847, was attended by deputies of only 151 congregations, and made new efforts to secure a permanent union of the two parties in the church. The revolutions of 1848 seemed to be very favorable. Austria and Bavaria opened their doors to German Catholicism, and congregations were at once formed in Vienna, Munich, and many of the important towns of both countries. Many of the congregations, however, declared themselves dissatisfied with the part which Ronge took in the politics of Germany. After the defeat of the revolution, German Catholicism was again forbidden in Austria

and Bavaria. The second council of Leipsic, which met May 22, 1850, had soon, on account of the interference of the police, to be transferred to Köthen; it proposed an alliance with the Free congregations, which had formed themselves by secession from the Protestant churches, and the election of a joint executive committee from both denominations, which was to act as a presiding board until the meeting of a triennial diet (*Tagsatzung*). These propositions were adopted by nearly all German Catholic congregations, and the first diet was fixed for 1852; but it did not meet. Since that time German Catholicism has been on the decline in nearly all parts of Germany, partly in consequence of the measures adopted against it by the governments, partly in consequence of the continual disagreement among its members. Many congregations disbanded; many others joined the Protestant church in a body. At a conference held at Gotha, Sept. 10, 1858, 42 representatives of the Free congregations and German Catholic congregations appeared, among them Czerski, Uhlich, Rupp, Wislicenus, Baltzer, and nearly all the other prominent leaders. New hopes were raised by the change of government in Prussia in Nov. 1858, which enabled them to reorganize their congregations in several Prussian towns.—The fullest history of German Catholicism is given by Kampe, *Geschichte der religiösen Bewegungen der neueren Zeit* (vol. iii., Leipsic, 1856). The current history of the denomination is given in various weekly journals: *Der Dissident* (Berlin), *Die Kirchenfackel* (Ulm), *Sonntagsblatt* (Gotha), *Deutschkatholisches Sonntagsblatt* (Wiesbaden), and *Königsberger Sonntagspost* (Königsberg).

GERMAN OCEAN. See NORTH SEA.

GERMAN SILVER, or ARGENTANE, an alloy resembling silver, made of variable proportions of its ingredients according to the uses for which it is designed. A composition of 8 parts of copper to 3 each of nickel and zinc is recommended as making a close imitation of silver of $\frac{750}{1000}$. The two latter metals are also used in the proportions of 4 each to 8 of copper. By using a larger proportion of copper the alloy is more easily rolled into plates, but the copper sooner becomes apparent in use. Iron used in the proportion of 2 to 2½ per cent. renders the composition whiter but more brittle. The genuine German silver, made from the original ore of Hildburghausen in Henneberg, analyzed by Keferstein, was found to consist of copper 40.4 per cent., nickel 31.6, zinc 25.4, iron 2.6.

GERMAN THEOLOGY. As the theology of the Catholic church of Germany, before as well as after the reformation, forms an inseparable part of the Roman Catholic system, the phrase German theology is commonly restricted to the doctrines of Protestant Germany. The theology of the Roman Catholic church during the middle ages, in the controversies with dissenting systems, both of those seceding from and of those remaining within the church, had more and more recognized the doctrine of the infallibility

of the church as its central dogma. As the Catholic theology knew of no regular way to secure salvation except through the one visible church, so there was no assurance of divine truth to be obtained except through the infallible decisions of the same body. Every apologist of that church had to fall back on this doctrine as his strongest and last fortress; every conviction that any doctrine of the Catholic church was unchristian had first of all to destroy this bulwark. Every attempt to establish a new theology had therefore to be preceded by the rejection of the formal principle of the Catholic theology, the infallibility of the church. The belief in this doctrine must have been shaken in many minds at the beginning of the 16th century, as we meet with so many attempts independent of each other to establish new systems of Christian theology on the ruins of the Catholic church. Foremost among the German reformers stands Martin Luther. He had early arrived at a theory of justification which contained the germ of dissent from the Catholic theology. The celebrated 95 theses, which on Oct. 31, 1517, he affixed to the gate of the Castle church of Wittenberg, were a challenge to the church authorities, but contain no evidence that their author was conscious of the necessity of an entirely new theology. But when, at the diet of Worms (April 17, 1521), he declared: "Unless I am refuted and convinced by proofs from the Holy Scriptures, . . . I yield my faith neither to the pope nor to the councils alone," the necessity of founding a new basis for theology was proclaimed. Next in prominence was Ulrich Zwingli of Zürich, who, even before Luther (in 1516), had begun to preach against what he considered unevangelical in the doctrines and practices of the church. The reformation of Calvin does not properly belong to Germany, though it was not without great influence on the Protestant theology of Germany and of German Switzerland. In 1529 Luther published in his two catechisms an outline of his new doctrinal system. In the following year, the "Confession of Augsburg" was drawn up at the request of the emperor Charles V., as a full exposition of the views of the Protestants, and presented at the diet of Augsburg. In 1531 Melancthon composed the "Apology of the Confession of Augsburg." These 3 works soon became for the Lutheran states an established basis of unity, and received an authoritative character as symbolical books. To them were added in 1537 the "Articles of Smalkald," which drew more distinctly the line of demarcation between the Catholic and the Protestant theologies; and later, in 1577, the "Form of Concord," which was directed against dissensions within the Lutheran church, and against the doctrines of Calvin. All these symbolical books were united in the "Book of Concord," which has ever since constituted the great charter of German Lutheranism. The Reformed (Calvinist) churches issued a large number of confessions of faith, of which, however, very few received more than a local

and temporary recognition as symbolical books. Three of them, the *Confessio Tetrapolitana*, the *Confessio Basiliensis*, and the first "Helvetic Confession," originated before the reformatory labors of Calvin; all those that followed show traces of his influence, though the German churches and their confessions of faith generally softened down the Calvinistic doctrine of predestination. The symbolical books of both the Lutherans and the Reformed, and of all the other reformers who independent of them attacked the Catholic theology during the 16th century, agree in recognizing the Bible as the only rule of faith. This implied the rejection of tradition as a second rule of faith, the rejection of the necessity of an infallible interpreter of the Bible, and the rejection of an authoritative translation (the Vulgate) sharing the inspired character of the original, and to be received as an ultimate appeal in theological controversies. So also in regard to the number of books constituting the Bible, the new theology differed from the Catholic, rejecting from the canon the apocryphal books, though Luther and with him the Lutheran churches considered them as books so "useful and good to read," that they kept them in their editions of the Bible as an appendix. As soon as the Scriptures were recognized as the only rule of faith, and the visible church was divested of its claim of infallibility, the question came up for decision, What is the Christian church? The whole theology of the reformation agreed in defining the church, so far as it is an object of faith, as the invisible communion of real Christians with Christ as the only head of the church. The Lutheran theology, however, introduced another element by defining it as the invisible communion of those to whom the gospel is rightly taught and the sacraments rightly administered. Zwingli viewed the church as the society of the elect. The most difficult question for the reformers to solve was, by what marks the true church could be recognized. Their true meaning became a subject of controversy, and has remained so to the present day. (Ritschle "On the Visible and the Invisible Church," in *Studien und Kritiken*, April, 1859.) The new theology having thus answered the inquiry, How to arrive at a knowledge of the Christian revelation, the second great question was, How is the salvation of man brought about? Here also the immediate relation of God to man and of man to God was substituted for the mediation of the church, and the leading principle of the biblical theology was found in the justification of man by faith alone. Closely connected with the doctrine of justification are the doctrines of original sin, grace, and predestination. The new theology taught that the state of perfect righteousness, holiness, and immortality, in which man was created after the image of God, was originally his true nature, and not an unessential gift added by God to his natural endowments (*donum superadditum*); that by the fall human nature became entirely corrupt, and lost all freedom of the will and all ability to do

good (on this point, however, Zwingli maintained a different opinion); that the sinner is justified by faith alone; that this faith is not merely a belief in historic facts and in promises, but one which embraces, recognizes, and appropriates to itself the merits of Christ. The sacraments were not alone recognized as the means of grace, but these combined with the word of God, and their number was reduced from seven to two. The means of grace were regarded not as *causa efficientes*, but as *causa instrumentales*; not as containing grace within themselves, but merely as conveying it, since the effect was made dependent on the faith of the receiver. They were, however, considered as essential. In opposition to the Anabaptists, both the Lutherans and Reformed denied that the Holy Spirit could be given without the external word. The difference between the Protestant and Catholic theologies in the doctrine of the sacraments showed itself especially in the sacrament of the Lord's supper, all the schools of Protestant theology unanimously rejecting transubstantiation and the sacrifice of the mass. The Catholic doctrines on the veneration of the saints and images, on purgatory and indulgences, so closely connected with the Catholic view of the church, were rejected with equal unanimity. While the two great reformatory schools of Germany agreed in recognizing the Bible as the only rule of faith, and while they further agreed in designating among the doctrines of the Catholic theology those which were to be regarded as unscriptural, they from the beginning disagreed as to a few particular points of scriptural doctrine. These points were especially the Lord's supper, the person of Christ, and predestination. Luther defined the Lord's supper as "the true body and blood of our Lord Jesus Christ, in and under bread and wine." He insisted on the real and actual presence of Christ in the eucharist. Some theologians of the Reformed church, with Zwingli and Ecolampadius, understood the words, "This is my body," as meaning "This signifies my body," regarding the celebration of the Lord's supper merely as a commemorative service; others, with Calvin, regarded it as a partaking of the spiritual body of Christ. With regard to the person of Christ, the Reformed strictly retained the doctrine of the two natures in one person, and confined the presence of the humanity of Christ to heaven. The Lutherans, on the other hand, assumed a real transition of the one nature into the other, a true and real though supernatural and undefinable union of the two natures, in consequence of which each, without losing its peculiarity, shares in the properties of the other (*communicatio idiomatum*); and from this they inferred the ubiquity of the body of Christ. The doctrine of predestination remained subject to many variations. Both Luther and Zwingli rejected the freedom of the will; but the absolute predestination of some to salvation and of others to eternal damnation received its consistent development only in the

system of Calvin. Melancthon taught (after 1535) that election or damnation was dependent only upon the different relation of the will to divine grace operating upon it; but in opposition to this, many Lutheran divines revived the opinion that predestination was independent of the doings of men. The differences of belief thus manifesting themselves between the leading theologians of Germany were at first not considered on any side as an insurmountable obstacle to a union. Several attempts to harmonize them were made, but failed. The symbolic determination of the Lutheran doctrine, and the doctrinal line of demarcation separating the Lutheran creed from the Reformed, gave rise to many controversies within the Lutheran churches. The Antinomian controversy, commenced during the lifetime of Luther and renewed in 1556, related to the obligatory character of the Mosaic law. The Osiandrian controversy, on justification and its relation to sanctification, originated with Andrew Osiander in 1550. The synergistic controversy, on the relation of human freedom to grace, was caused in 1555 by a work of Pfeffinger, renewing an opinion of Melancthon. The controversy on good works, commenced in 1559, was carried on between George Major and Nicolas von Amsdorf, the former maintaining that with a justifying faith good works must necessarily be connected. The so called Crypto-Calvinistic controversy was carried on after 1559 with the orthodox Lutherans concerning the Lord's supper. The Flacian controversy, between Strigel and Flacius, dating from 1560, related to the essence of original sin. It was generally considered as right that the highest authorities in the church should put an end to these and all other controversies, by declaring which was the true doctrine of the Bible. This was attempted by the "Form of Concord," in 1577, but with only partial success, as many of the state churches refused to accept it. Yet it became, in union with the other books, now clothed with symbolic authority, the basis of a Lutheran orthodoxy, which reigned in the larger portion of Protestant Germany with undisputed sway until the middle of the 17th century. The only interruption in the consolidation of the Lutheran theology toward the close of this period was caused by George Calixtus of Helmstädt, who in the spirit of Melancthon sought for a more unfettered form of theology, and even thought that Catholic and Protestant theologies might once more be united by returning to the oecumenical synods of the first 5 centuries, which plan was called by his Lutheran opponents syncretism. The further development of the Reformed church took place mostly in other countries, and affected German theology but little, the most important event in which was the adoption of the catechism of Heidelberg, which gave prominence to the doctrine of divine predestination only so far as it seemed needful to console the Christian with the certainty of redemption, and to that of the eucharist only to impart an assurance of

communion with Christ. One of the doctrines of both the two great reformatory schools, paedobaptism, was rejected as unscriptural by Thomas Münzer (died 1525) and the Anabaptists; and after their views had been suppressed by force, the peaceful community of Mennonites perpetuated the opposition to paedobaptism, though not to the formal principle of the German reformation, which they fully adopted. The Socinian theology belongs only in part to Germany. Its advocates generally recognized the Scriptures as the rule of faith, but demanded at the same time that every opinion contrary to reason should be rejected, thus at least virtually making the Bible interpreted by reason the rule of faith.—A theological principle differing from the Lutheran and Reformed systems, as well as from Socinianism, was developed by Protestant mysticism, which placed by the side of the Bible (in which it emphatically distinguished between the spirit and the letter, frequently identifying the former with Christ) a continuous direct revelation of God in the human soul, as a source of knowledge, and which made the living union with God by means of contemplation and asceticism its most important and central doctrine. It showed itself mostly within the Lutheran church, with which many of its chief representatives strove to remain in external connection, though they never escaped the charge of heterodoxy, and often expressly rejected some of the Lutheran doctrines, and especially justification by faith. The chief representatives of Protestant mysticism, among the contemporaries of Luther, were Münzer, Carlstadt, Schwenkfeld, and Sebastian Frank; later appeared Valentin Weigel, and the greatest of Protestant mystics, Jacob Boehm, whose theosophic system has exercised a marked influence on both the theological and philosophical literature of Germany, even to the present day.—A new movement in German theology arose in the second half of the 17th century through Philipp Jacob Spener, the founder of pietism. Though not openly attacking the dogma in the symbolical form which it had obtained in the prevailing Lutheran theology, pietism considered the stress which had been laid on the theological definition and symbolical determination of the Christian doctrines as ill agreeing with the simplicity of the gospel, and as estranging Christianity from life; and it strove to free it from this estrangement by a return to a practical, biblical, and more inward piety. The central principle of pietism was that Christianity was first of all life, and that the strongest proof of the truth of its doctrines was to be found in the religious experience of the believing subject. As Lutheran orthodoxy grounded Christian theology on the Bible as explained by the symbolical books, so Spener based it on the Bible confirmed and explained by individual religious experience. The theology of the Lutheran schools with almost one voice exclaimed against pietism as a new sect, and the theological faculty of Wittenberg designated in the writings of Spener about 300

false doctrines, yet Spener protested that he accepted the whole "Confession of Augsburg." On scientific theology and its development the influence of Spener was not great, and showed itself mostly by shaking the authority of the Lutheran symbols; but the prayer meetings (*collegia pietatis*) and conventicles (*ecclesiola in ecclesia*) in which he gathered the awakened, created a popular and strictly biblical theology, which perpetuated itself, especially in Württemberg, in several sects, and never ceased to have some representatives in the theological literature and in the chairs of theology. The principles of the pietists were in the main also shared by the Moravians, reorganized in 1724 by Count Zinzendorf. They declared their agreement with the "Confession of Augsburg," but expressly rejected all other symbolical books. The centre of their theology was the cleansing power of the blood of Christ; they regarded themselves as a society for awakening piety, and as such were of marked influence in the history of the religious life of Germany, but of little in the history of German theology.—Almost simultaneously with the rise of pietism begins the influence of philosophy on theology, which more than any other agency drew theology into that direction in which it subsequently developed itself. Both influences had this in common, that they were a transition to a standpoint on which the subject, in opposition to the objectivity of the dogma, strove to constitute itself the determining, absolute principle. But pietism sought in the religious feelings only a confirmation of the revealed theology of the Bible; while philosophy, to which Descartes had assigned the task of finding something absolutely true and certain, had gradually the effect of making the belief in the doctrine of the church, in the Scriptures, and in religion itself, dependent upon the judgment of man's reason. The first step toward this transformation of the formal principle of Protestantism was made when Wolf (1679–1754) introduced into theology his distinction between natural and revealed theology, and a number of "rational thoughts," by which he became the father of German rationalism, though he and his adherents defended most emphatically the harmony of their philosophic system with the revealed word. The system of Wolf was adopted by numerous theologians of both the Lutheran and Reformed churches, and thus at once deeply penetrated into theological literature and theological schools. A contemporary of Wolf, J. A. Ernesti, established the historico-critical school of Protestant exegesis by applying the rules of classic philology to the interpretation of the Bible. Though remaining on the whole faithful to the doctrinal system of his church, he made an attempt to define some of its tenets more accurately according to the results of his critical investigations. Semler (1725–91) distinguished theology from religion (i. e. morality); claimed the right to subject the whole canon to the freest investigation; distinguished between a local,

temporal, and therefore transitory part of the Bible, and the imperishable word of God; and laid down as a supreme principle that the Scriptures are to be regarded as canonical and of divine origin only so far as their contents are of an ethical nature. W. A. Teller (1784–1804) published, on the basis of the biblical studies of Ernesti, Semler, and their followers Michaelis and Eichhorn, a new and purely biblical system of Christian doctrine, and proclaimed a practical religion of reason as the essence of Christianity. A new theory of far-reaching influence was set forth by Töllner (died 1774), who distinguished between Holy Writ and the word of God, the latter of which he found also in all other religions and in reason. He distinguished different degrees in inspiration, and maintained that neither the highest degree belonged to the Scriptures, nor the same degree to all its parts. Against the invasion of this new school the orthodox theology was principally defended by the pietistico-mystic works of Bengel and Crusius, by the theosophic prelate Oettinger, by Zollikofer and Spalding.—English deism was transplanted to German soil by Reimarus (1694–1768) in the celebrated "Wolfenbüttel Fragments," first published by Lessing. He denied the possibility of a revelation, ascribed to Jesus the design of making himself, under the pretext of introducing a new religion, the king of a new Jewish empire, and declared as the principal doctrines of natural religion, which alone he admitted, the doctrines of God, of divine providence, and of the immortality of the soul. The same views as to the truth of natural religion alone we find in the writings of Moses Mendelssohn, a Jew (1729–86), who declared the happiness of man to be the principal aim of religion. Other writers of the same school, as Steinbart (1738–1809), Baschew (1738–90), and Bahrdt (1741–92), endeavored to show that these principal doctrines of natural religion constituted also the essence of Christianity, and frequently made not so much reason as happiness the measure by which the truth of every opinion was to be tested. An important organ of the new theology of "enlightenment" (*Aufklärung*) was the *Allgemeine deutsche Bibliothek*, published (1765–92) by Nicolai. Lessing (1729–81) also partly belonged to this school, though he directed his attacks against the shallowness of the theologians of enlightenment no less than against Lutheran orthodoxy. He maintained that a revelation, to which all men can yield a rational faith, is impossible; that reason alone can determine whether there can and must be a revelation, and which among the many systems that claim to have been revealed is probably a revelation; that revelation gives to man nothing more than reason alone would have sufficiently developed in time; that it is essentially a system of education for mankind, in which the Scriptures are text-books, which may perhaps be superseded when humanity is educated for the reception of the new everlasting gospel.

The path marked out by Lessing was further pursued by Kant (1724-1804), who went into a careful investigation of the faculty of understanding, and arrived at the conclusion that we cannot know things in themselves, and things above the reach of the senses, but that the only thing certain in itself is the moral law, which conducts us to a practical faith in God and immortality. Through him the terms rationalist (one who declares natural religion alone to be morally necessary, though he may admit revelation), naturalist (one who denies the reality of a supernatural divine revelation), and supranaturalist (one who considers the belief in revelation a necessary element in religion) came into use, and rationalism and supranaturalism became the principal division of theological schools. The principles of the Kantian philosophy were introduced into theology especially by Stäudlin and Ammon. The first rationalistic system of dogmatic theology was published by Henke, and the most complete and most celebrated (*Institutiones Theologiae Dogmaticae*, 1813) by Wegscheider (1771-1849); beside whom Paulus of Heidelberg (died 1851), the author of a "Commentary on the New Testament" and of a "Life of Jesus," and Röhr of Weimar (died 1848), author of "Letters on Rationalism," were considered the ablest rationalistic theologians. The foremost representatives of the supranaturalist theology were Storr (died 1805), Knapp, Hahn ("Manual of the Christian Doctrine"), and Steudel. A medium between rationalism and supranaturalism was first attempted by Reinhard, the great German pulpit orator (died 1812), from which time rationalism made decided advances toward the Christian revelation, and supranaturalism acknowledged the possibility and necessity of a reconciliation with science. The most prominent representatives of this mediating theology are Schott (died 1835) and Bretschneider (died 1846). An academic disputation at Leipsic in 1827, and the "Evangelical Church Gazette" of Hengstenberg in 1830, demanded the expulsion of rationalism from the church; against which, however, even men like Neander, Ullmann, and others, protested as an encroachment on the liberty of scientific investigation. As Kant had declared the ideas of God, liberty, and immortality indemonstrable by pure reason, but admitted them as postulates of practical reason, another philosophy, the philosophy of faith (*Glaubensphilosophie*), sought to prove the Kantian postulates theoretically, by attributing to man an immediate consciousness of God, or an innate faith. This idea was the basis of the theological views of Hamann, the "Magus of the North" (died 1788), and of Herder (died 1803), who, as has been said, mixed it with the foam of Spinozism; and it was developed as a philosophical system by Jacobi (died 1819). The influence of the latter on theology was small, for he limited himself to a philosophical proof of the idea of a living God, did not explain his views of the Christian revelation, and

rejected a part of the positive doctrines of Christianity as superstition. J. F. Fries (died 1843) attempted a mediation between Kant and Jacobi by a philosophy of faith and presentiment. He found among the theologians an adherent of influence in De Wette (died 1849), who explained religion as an immediate inner revelation of God in sentiment and faith, and dogma as its symbolic form of expression and development.—Not a mere approximation or partial mediation between rationalism and supranaturalism, but a merging of the two into an entirely new system which was to acknowledge the claims of both, was the task which Schleiermacher (died 1834) proposed to himself. Like the pietists, he started from the principle that a right knowledge of Christianity necessarily presupposes on the part of the subject a personal religious experience. He found the proper source of all Christian life and knowledge in the pious sentiment or Christian consciousness, in which the subject comprehends itself both in the totality of its being, as also in its necessary connection with the human race, and in its being determined by the Christian principle reigning in the race. In this consciousness it becomes assured of the reality of a new, divine, world-redeeming principle of life, which reveals itself in Christianity, and without which the restoration of the right relation of individuals as well as the human race to God is not possible. Revelation is according to him not an external law, claiming submission from the subjective reason; but nothing more is demanded from the latter than to recognize itself as being determined by the Christian principle, and more and more to penetrate itself with it. The external opposition of revelation and reason is supplanted by the closest interpenetration of the two, allowing the greatest freedom with regard to such questions as do not affect the proper sphere of revelation. The movement in the theological world called forth by this system was extraordinary, and can be compared in intensity only with the reformation of the 16th century. Not only did several different theological schools spring from it, but even the schools opposed to it felt its influence. Most of the adherents of Schleiermacher defended from his standpoint all the essential doctrines of biblical orthodoxy; thus Neander ("Church History"), Ullmann ("Sinlessness of Jesus," and "Essence of Christianity"), Lacke, Umbreit, and Olshausen (commentaries), Hundeshagen, &c. Others attempted a middle course between the system of Schleiermacher and those of the German Protestant churches, as Twisten ("Dogmatics") Nitzsch ("System of the Christian Doctrine"), and J. Müller ("Christian Doctrine of Sin"). A third school, however, rejected these two as deviations from the true spirit of Schleiermacher, and claimed the fullest independence of theological investigation with regard to the doctrines both of the biblical and the church theologies. To this school belong A. Schweizer ("Dogmatics of the

Evangelical Reformed Church") and Baumgarten-Crusius ("Dogmatics").—The most recent influence of lasting importance in the development of German theology came from the philosophy of the absolute, which was first introduced by Schelling (1775–1854), but completed as a system by Hegel (1770–1831). In the view of this philosophy, the popular religions which have existed in the world have been the several points by which the divine self-consciousness has developed itself. The essence of religion consists in the relation of man to God. Christianity is called the absolute religion, the realization of the idea of religion, because it presents the unity of the divine and the human, God becoming man, and man becoming conscious of his divine origin and his reconciliation with God. The idea of revelation ceases to be something external, particular, miraculous, and once occurring, and becomes something internal, universal, necessary, and eternal. After the death of Hegel his school became divided into those who used an orthodox and those who used a heterodox mode of expression, or into the right and left wings. The former, full of enthusiasm, proclaimed the identity between the new speculative philosophy and the orthodox dogma, the reconciliation between faith and knowledge. Among its numerous representatives, Daub ("Dogmatics"), Marheineke ("Outlines of Christian Dogmatics"), Rosenkranz ("Cyclopædia of Theological Sciences"), Göschel, Erdmann, and Conradi, were prominent. The last named contended that it was consistently developing the fundamental idea of the master when it proclaimed that religion, carried to its perfection by reason, is only a god worshipping himself, and that a god-man is one who never had an existence as an individual upon earth. From the latter school (the young Hegelians) proceeded D. F. Strauss, who in his "Life of Jesus" (1835) declared the biblical account of the life of Jesus a myth, and in his "Christian Doctrine in its Historic Development" (1840) attacked even the belief in the personality of God and the immortality of the human soul. L. Feuerbach ("Essence of Christianity," 1841) went even beyond Strauss, to the extreme limit of nihilism; he rejected religion itself as a dream and illusion, from which when man awakes he finds only himself. Under the influence of both Schleiermacher and Hegel, F. Ch. Baur of Tübingen introduced the philosophy of religion as a Christian science into the history of Christian doctrines, and in monographs on the history of the doctrine of the Trinity and of reconciliation he sought to comprehend the historic development of the dogma as the dialectic process of the idea itself, and as the development of the undeveloped doctrine of the Bible into a more adequate unity of contents and form. Rejecting the authenticity of most of the books of the New Testament, and ascribing to them a later origin, he endeavored by numerous writings to fill up the vacuum thus left in the history of Christ

and earlier Christianity; in which endeavors he was seconded by a considerable number of young scholars (the Tübingen school), among whom Schweigler ("History of Montanism" and "Post-apostolic Age") and Zeller ("Investigations on the Acts") were the most prominent. The critical works of the Tübingen school called forth an immense number of opponents, who partly modified the new assertions, partly vindicated the old-established views of the churches, but all of whom agreed that by the numerous works thus called forth on both sides a flood of light had been shed on many important events of primitive Christianity. The most important controversial essays against the Tübingen school were those of Thiersch ("Church in the Apostolic Age"), Dörner ("Doctrine of the Person of Christ"), Schaff, ("Apostolic Age"), Bleek, ("Contributions to the Criticism on the Gospels"), Hase ("On the Tübingen School"), Ewald ("Annals of Biblical Science," "The First Three Gospels," and "History of Christ and his Times").—The impulse given to German theology by the various systems of speculative philosophy was a general one, and not confined to the schools that revered Schleiermacher and Hegel as their masters. Many supranaturalists as well as rationalists were greatly influenced by it, though with regard to the systems of Schleiermacher and Hegel they sustained either an eclectic or an independent relation. Thus especially Liebnert, Lange, and Martensen, each the author of a system of dogmatics, were called the epigoni of speculative theology; the ingenious R. Rothe, whose "Christian Ethics" has been called the most important theological work of Germany since the publication of the "Dogmatics" of Schleiermacher, designated himself as a theosophist; Hase, the church historian, is a prominent representative of speculative rationalism. Speculative theology itself is still in a course of active development. Schelling's "Philosophy of Mythology and Revelation" (the exposition of his second philosophic system, published only after his death) aimed at a fuller reconciliation between speculative theology and the Christian revelation, and to prove the absolute universality of the Christian principles; while on the other hand T. H. Fichte ("Speculative Theology"), O. Ph. Fischer ("Idea of the Deity"), Weiss ("Idea of the Deity"), Wirth ("Speculative Idea of the Deity"), and others, established, in opposition to the pantheistic tendencies of Hegel, the system of speculative theism (*Panentheism*), in which they hope to bring about a reconciliation between deism and pantheism.—In opposition to the rationalistic and speculative theology, as well as to the vague supranaturalism of the 18th century, there developed itself at the beginning of the present century a school which demanded a restoration of the original theology of the Reformed churches, and a return to the strict orthodoxy of the symbolical books. One of the first manifestations of this school was the publication of the

95 theses of Claus Harms of Kiel, in 1817; later it received an influential organ in the "Evangelical Church Gazette" of Hengstenberg, and on many sides it was demanded that all the ministers and theological faculties of the established churches should be pledged to a strict conformity with the symbolical books. It was, however, almost exclusively a Lutheran orthodoxy which was thus restored. Its principal theologians are Hengstenberg, Hävernick, Keil, Kliefoth, Kahnis, Rudelbach, Guericke, Delitzsch, with a host of others; its theological organs are the "Journal of the Lutheran Theology and Church," by Rudelbach and Guericke, the "Journal of Protestantism and the Church," by the theological faculty of Erlangen, and the "Church Journal," published by Kliefoth and Meier. This revived Lutheran theology, however, soon split into an old and a new Lutheran school; some of the latter, in particular the professors Hoffmann and Thomasius of Erlangen, were charged with having introduced into the Lutheran theology the most dangerous innovations; and finally another party, likewise proceeding from the new Lutheran school, and counting among its leaders Vilmar, Löhe, and Münchmeyer, were suspected of leaning in the doctrine of the church toward the Catholic theology. There were also not wanting theologians who, though not sharing with the Lutheran schools the strong attachment to the symbolical books, yet united with them in the defence of the Bible as the only rule of faith, and of an unaltered biblical theology. Among them Tholuck is best known. The rise of new denominations in Germany has as yet not had an influence on German theology; only Irvingism has found a representative (Thiersch) among the leading theologians of Germany.—As the above sketch traces only the development of theology as a system, it must be remarked, in conclusion, that in every single department of German theology an exceedingly voluminous and thorough literature has been produced, and that some branches of theology have been cultivated almost exclusively in Germany.—The history of Christian doctrines has become in late years a particular branch of German theology. Among the numerous works we mention the *Dogmengeschichten* of Augusti (4th ed., 1884), Münscher, Baumgarten-Crusius, Hagenbach, Meier (new ed. by G. Baur, 1864), F. O. Baur, Beck, Marheineke, Strauss, and Noack. The most complete work on the history of German theology during the last 25 years is by Karl Schwarz: *Zur Geschichte der neuesten Theologie* (8d ed., Leipsic, 1858). A survey of the best works in every department of German theology may be found in Hagenbach's *Encyclopädie und Methodologie der theologischen Wissenschaften* (Leipsic, 1833). Winer's *Handbuch der theologischen Literatur* (3d ed. 2 vols., Leipsic, 1838) contains a complete list of all the theological works of Germany.

GERMANICUS CÆSAR, a Roman general, born in Rome in 15 B. C., died near Antioch in

A. D. 19. He was the son of Claudius Nero Drusus and Antonia, the daughter of the triumvir Antony, and was adopted by his uncle Tiberius in accordance with the will of Augustus. In A. D. 7 he accompanied Tiberius against the rebels of Dalmatia, served with distinction during 3 campaigns, and on his return to Rome was rewarded with a triumph, and with the hand of Agrippina, granddaughter of Augustus. At the close of another campaign, in A. D. 11, he was made consul, and in the following year was placed in command of the 8 legions on the Rhine. He was absent in Gaul when upon the death of Augustus (A. D. 14) a universal sedition broke out in the army. He was a favorite with the soldiers, and they had already determined to raise him to the head of the empire, when he suddenly returned to the camp, and at the peril of his life and by an admirable firmness succeeded in repressing 2 successive revolts and in establishing Tiberius upon the throne. He immediately marched the pacified legions against the enemy across the Rhine, and routed the Marai, whom he fell upon by night as they were celebrating a festival. Soon after appointed commander-in-chief of all the legions of Germany, he began that series of exploits which gained him his title of Germanicus. He marched against the native hero Arminius (Hermann), the conqueror of Varus, and defeated him, making his wife Thusnelda prisoner. He then penetrated to the Teutoburg forest, north of the Lippe, the scene of Varus's disaster, and rendered the honors of burial to the whitened bones of the legionaries that had fallen there. Yet Arminius hovered about the Roman army in impracticable places, attacked it in a narrow pass, and drove it into a marsh with so great loss that Germanicus decided to retreat to the Rhine. In A. D. 16 Germanicus returned against the Germans with a fleet of 1,000 vessels, landed his forces at the mouth of the Ems, crossed the Ems and the Weser, and defeated Arminius first on the plains of Idistavisus and then in the vicinity of Minden, but was again obliged to retreat, and lost a part of his fleet in a storm, after he had reached it with difficulty. He purposed to pursue his advantages in the following year, when Tiberius, jealous of the glory attached to his name, recalled him, and in the triumph which was granted him Thusnelda figured among the captives. To rid himself of Germanicus, the emperor sent him to the East to fight the Parthians and to pacify Armenia. He at the same time gave the government of Syria to Cneius Piso, a man of violent and haughty character, with secret instructions to thwart and annoy Germanicus. The latter calmed the disturbances of the East in spite of the intrigues of his enemies, but suddenly fell ill and died at Antioch. Agrippina brought his ashes to Italy amid universal mourning; honors almost unexampled in Roman history were paid to his memory; and Piso, accused by the senate of having poisoned him, anticipated his condemnation by a voluntary death. Germanicus is

the hero of the "Annals" of Tacitus, and is one of the noblest characters in the history of the Roman empire. He had reputation also as an orator and poet, but of several works which he composed there remains only a Latin translation of the *Phænomena* of Aratus, which is superior to Cicero's translation of the same work.

GERMANY (Germ. *Deutschland*; Fr. *Allemagne*), the name given to a large portion of central Europe, composed of numerous independent states, and parts of states, united together by a common league, called the Germanic confederation, embracing the river system of the Elbe and Oder, and large portions of the systems of the Rhine, Danube, and Vistula. It extends from the southern point of the Istrian peninsula on the Adriatic (lat. 44° 50' N.), over 10 degrees 5 minutes of latitude, to the lake of Zarnovitz on the boundary of Pomerania and western Prussia, and over 18 degrees 40 minutes of longitude from the westernmost point of the duchy of Limburg, long. 5° 37' 21" E., to the eastern boundary of Silesia, long. 19° 17' 21" E. The boundary line marked off by these extreme points has a length of about 4,600 miles, and encloses an area of about 244,000 sq. m. (The area of 280,000 sq. m., given by some authorities, includes the eastern provinces of Prussia lying beyond the limits of the German confederation.) The natural boundaries are, on the N., the German ocean (North sea), the Eider river, and the Baltic sea; on the E., the water-shed of the Oder and Vistula rivers, and the lesser Carpathians; on the S., the Alpine system and the Adriatic; on the W., the water-shed of the Rhine, the Moselle, and the Meuse. Politically Germany is bounded N. by Denmark; E. by Prussian, Russian, and Austrian Poland, Hungary, and Croatia; S. by Italy and Switzerland; W. by France, Belgium, and Holland. Stretching from the lofty summits of the Alps to the low beaches of the Baltic, from the picturesque and diversified countries of western Europe to the monotonous steppes of the east, Germany encloses a rich variety of mountainous regions, terraced country, table-lands, and fertile plains. Though mainly an inland country, it is not devoid of a coast configuration which, if less favorable to a large development of maritime commerce, furnishes good outlets to its numerous navigable rivers. Two river systems, tributary to the North sea and the Black sea, meet in Germany, rendering it the centre of the interior commerce of the European continent. Its climate unites the different characteristics of the surrounding countries, holding a mean between the extreme heat of the south and the extreme cold of northern Europe, between the excessive moisture of the western coast countries and the dryness of the eastern plains. Since the time when Germany ceased to be a conquering nation, the preservation of its political status has always been considered the principal element of the balance of power in Europe. In that respect it is the keystone of the political

system of Europe. Owing to its important central position, Germany has almost invariably become the theatre of all great European wars, no matter where or for what cause begun. Beside, its boundaries, with the exception of the southern, are but poorly protected. On the W. its former principal defensive positions against France, viz., the Netherlands, Alsace, and Switzerland, have been lost. On the central portion of the Rhine France cuts deeply, almost at a right angle, into Germany, and the valleys of the Main and Kinzig rivers form an easy road for a French invading army. Hence 6 strong fortresses, Mentz, Coblenz, Luxemburg, Saarlouis, Landau, and Germersheim, cluster there as bulwarks against French invasion, while a similar number of equally strong fortresses on the French side would appear to be intended more for aggression than defence. On the S. E. Germany is protected by the maze of the projecting spurs of the Alpine system and the mountainous character of Bohemia. The weakest point of Germany is the E. and N. E. frontier toward Russia. There the Russian territory enters like a wedge into the side of Germany, and the three fortresses of Posen, Thorn, and Königsberg could scarcely offer any successful resistance to an invading army from Russia. Nevertheless the defensive military power of united Germany would be so strong as to deter all attempts at conquest, and it is not only the boast of the Germans, but also believed by their neighbors, that Germany as a united nation would be fully able to cope with both France and Russia simultaneously. But Germany as a unit has always been a chimera. To the diversified physiognomy of its vast territory corresponds a political division scarcely less variegated. It has been said by an eminent German statesman that Germany is not a nation, but merely a geographical designation. Indeed, the tie connecting the different members of its political body is so weak as to be of very little utility. Practically, Germany appears only as a vast conglomerate of a multitude of petty states, half a dozen states of the second or third rank, and two great European powers, both of which have large possessions beyond the limits of Germany proper. Germany has never been a centralized nation, and it is a significant fact that its precise centre is cut up into the pettiest and weakest principalities. Even during the middle ages, when Germany was at the zenith of its power, in fact the ruling nation of Europe, political power always rested with the limbs, not with the main body of the empire. Since the time of the reformation, Germany has almost incessantly been rent by a dualism deeply rooted in the national and individual peculiarities of the northern and southern sections. Northern Germany, grouped around Prussia, is the representative of the highest development of mental culture, and the diversification of human labor; while southern Germany has been slow in the development of intellectual culture, more prone to conquest by force of arms, and

less so to that higher form of conquest which consists in the subjection of nature to the wants of mankind and the fullest development of natural resources.—The population of Germany, according to the latest complete census (Dec. 1855), was 43,985,500, or 180 to the square mile, showing an increase within the 12 years preceding of 0.6 per cent. per annum (in 1848, 41,054,702). The density of population was, in 1801, 112 to the square mile; in 1816, 125; in 1837, 140; and in 1848, 168. The 4 free cities excepted, the greatest density of population prevails in the kingdom of Saxony (348 to the square mile), the grand duchy of Hesse (264), and the duchy of Saxe-Altenburg (256). In the following states the density of population exceeds the average: Hesse-Cassel, Württemberg, Baden, the Prussian provinces belonging to the German confederation, Luxemburg, Nassau, Brunswick, Saxe-Coburg-Gotha, Schwarzburg, Reuss, Lippe, Hesse-Homburg, Saxe-Weimar. The average density of the German provinces of Austria is 170, of Bavaria 154, and of all the other states less than 140 (Hanover 122, the lowest average). The proportion of the inhabitants of cities to the rural population is in the general average as 1 to 3; in Prussia as 2 to 5, in Saxony as 1 to 2. The number of large cities is, proportionately to the population, larger in Germany than in any other country, Great Britain, Belgium, and Holland only excepted. There are 2 cities with over 400,000 inhabitants each (Vienna, 478,000, and Berlin, 426,602, not counting the garrisons); 6 with more than 100,000 and less than 150,000 inhabitants (Breslau, Prague, Munich, Hamburg, Dresden, Cologne); 12 with 50,000 to 100,000 inhabitants (Leipsic, Frankfort-on-the-Main, Bremen, Magdeburg, Stettin, Aix la Chapelle, Trieste, Brunn, Grätz, Nuremberg, Stuttgart, and Hanover); over 100 cities with from 10,000 to 50,000; about 200 with from 5,000 to 10,000; nearly 2,000 with less than 5,000 inhabitants; about 3,000 boroughs and 112,000 villages. Four-fifths (80.8 per cent.) of the population of Germany belong to the German race; the remaining fifth, belonging principally to the Slavic race, is mainly confined to the Austrian and eastern Prussian provinces. If these are left out of account, full 98½ per cent. of the German people belong to the same Teutonic stock. The entire number of Slavi in Germany is a little over 7,000,000, or 16.75 per cent., of which number there are only about 50,000 outside of Prussia and Austria. The number of Jews is about 440,000, or 1 per cent. of the total population. They are very unequally distributed. While scarcely any reside in Upper Austria, Styria, Carinthia, Carniola, and Tyrol, and in the Prussian province of Saxony they are only ½, and in Saxony ¼ per cent., they are 8 per cent. of the population of Hamburg, Frankfort, and Hesse. The Romanic population in Tyrol and Illyria number about 400,000, the Flemings in Rhenish Prussia and Luxemburg about 200,000, Greeks (in Austria) some 3,000, gypsies over

1,000, principally in Austria. The Germans are usually classified into low Germans and high Germans, or northerners and southerners. The dividing line may be drawn from lat. 50° 30' N. in western Germany to lat. 52° 30' N. on the eastern frontier, or along the course of the Sieg (a tributary of the Rhine) to the southern slope of the Hartz mountains, crossing the Elbe near its confluence with the Saale, then a little to the northward along the southern banks of the Havel and of the Warthe. In physical development the Germans stand superior to either the Latin or the Slavic race. Their frame and their muscular development are strong, almost heavy. Among the lower classes of the rural and laboring population stoutness and strength often approach to clumsiness, which is heightened sometimes by a servile bearing, and a certain uneasiness and want of self-reliance. As a general thing the northerners are taller and of better shaped features and limbs than the southerners. The blonde complexion prevails only in the north; in central and southern Germany light or dark brown is more frequently found. In power of endurance the Germans are surpassed by the Slavic race, in agility by the Latin. The prominent features of the German national character are honesty, faithfulness, valor, thoughtfulness, perseverance, and industry. The German is patient, conservative, inoffensive, and hence always ready to allow himself to be deceived by vain promises of his rulers. He favors a moderate enjoyment of the pleasures of social life, but sometimes, or it should rather be said in some portions of Germany, this is carried to excess, and the complaint has been heard that popular movements in favor of liberty have unfortunately been drowned in the social cup. Of a scientific turn of mind, the Germans have largely promoted the progress of human knowledge. In point of fact, there is scarcely a single branch of science in which Germans have not excelled. Again, in music, painting, and sculpture they occupy one of the highest ranks among nations. The German artisan is highly valued for his dexterity and steadiness. Yet there is one element almost entirely wanting in the German character, viz., a strong national feeling. The German rather boasts of being a cosmopolitan, while in fact his cosmopolitanism would appear to be only a confession of weakness and pliability. The German differs from the natives of all other European and American countries in this respect, that he is in many instances more favorably inclined toward other countries than his own. If proverbs are indicative of the sentiments of the people, it is hardly creditable to the patriotism of the Germans that they are wont to call those things which they deem of little value, "things that have not come from afar." Some German authors contend that these peculiar traits of the national character are merely fruits of the political condition of the country; but they result more probably from an abstract idealism with which the majority of Germans would seem to

be imbued. Among the multitudes of emigrants whom Germany sends forth to other continents, there are many thousands with whom the motive for voluntary expatriation is not social or individual misfortune, but merely a visionary longing after an ideal state of society. The sectional and local diversities of character are very great in Germany. While the Protestant northerners have many characteristics in common with the Anglo-Saxon, the Catholic southerners approach in some important respects the Latin race, particularly in a certain preponderance of imagination over reason. The low German assimilates far more readily to the English or American than to the Austrian or Swabian. In fact, the political division of Germany has, in its general features at least, a firm foundation in the diversities of the popular character by which a centralized form of government for the whole country would seem to be rendered all but impossible.—The vertical configuration of Germany presents 8 principal groups, viz.: 1, the Alpine region, S. of the Danube, comprising about 45,000 sq. m.; 2, the elevated and terraced central portion, over 100,000 sq. m. in extent; 3, the level northern country, comprising about 100,000 sq. m. 1. The principal chain of the German Alps extends from W. to E. nearly along the 47th parallel of latitude, bearing the names of Rætian Alps and Noric Alps, the former sending a branch to the northward (Algau Alps), the latter being subdivided into the Trentine, Salzburg, Styrian, and Austrian Alps, and branches off to the N. N. E. in the Wienerwald (Viennese forest). The western portion of this mountain system (Tyrol) rises in gigantic and precipitous masses, and is distinguished by the sombre grandeur of its scenery. It culminates in the Ortelope peak and the Groes-Glockner (12,218 feet according to the latest statements), the highest mountain of Germany. The Inn, Salza, Enns, Adige, and Drave rivers rise from this section of the Alps. The eastern section, the physiognomy of which is determined by the valley of the Mur river, offers less striking features of mountain scenery, and few of its highest elevations attain the limit of perpetual snow. To the S. the Noric Alps gradually slope toward the plains on the northern bank of the Drave. On the other bank of the river the ridge of the Carnic Alps forms a watershed between the Drave and the Save. Again, between the Save and the gulf of Trieste the Julian Alps stretch in a S. E. direction from the western portion of Illyria toward Dalmatia. 2. The terraced country of central Germany E. of the Rhine has its nucleus near the junction of the boundaries of Saxony, Bohemia, and Bavaria, about lat. 50° N., in the Fichtelgebirge, the watershed of the tributaries of the Rhine, Danube, and Elbe. Thence a number of mountain chains of the secondary order radiate in all directions. To the S. E. the Bohemian forest runs nearly 150 miles in parallel rugged chains toward the Danube,

where it terminates abruptly opposite Lintz. Its highest elevation is the Great Arber, 4,650 feet high. To the N. E. the Erzgebirge, the loftiest peaks of which rise to an elevation of 4,000 feet, forms the frontier between Bohemia and Saxony. On the right bank of the Elbe they cluster in a group of sandstone mountains (Saxon Switzerland and Lusatia); after which, assuming the name of Sudetic mountains (Riesengebirge, Glatzergebirge), they turn S. E., dividing Bohemia from Silesia, and extending to the head waters of the Oder, where they meet the Carpathians. They culminate in the Schneekoppe, 4,960 feet high. Nearly parallel to the Erzgebirge, from the point where the Bohemian forest approaches the Danube to the Glatzer section of the Sudetic mountains, run the Moravian mountains. Thus Bohemia, enclosed between 4 high mountain ridges in the shape of a parallelogram, appears as a vast hilly basin, or, in a historical aspect, as an immense fortified *place d'armes*, the command of which has at all times been considered essential in the wars of conquest fought upon German soil. To the S. E. of the Fichtelgebirge the Franconian Jura sweeps to the Danube and along its northern bank in a westerly direction into Wurtemberg, where its long stretched, sharply defined ridges and table-lands are known by the names of Raube Alp, Swabian Alp, Aalbuch, &c. In the S. W. corner of Germany (grand duchy of Baden), near the head waters of the Danube, the mountain ridge of the Black forest sets off at a sharp angle from the Swabian Alp in a northerly direction, nearly parallel to the Rhine, and skirting the fertile bottom-land of its E. bank. The spurs of this ridge, extending as far N. as the Neckar river, there meet with the Odenwald (grand duchy of Hesse), which, by the Spessart and Rhön (N. W. frontier of Bavaria), and again by the Thuringian and Franconian forests, is connected with the Fichtelgebirge. The territory enclosed by these different ridges, being those sections of Bavaria and Wurtemberg N. of the Danube, nearly the whole of Baden, part of the grand duchy of Hesse, and a few of the petty Saxon duchies, is intersected by a number of lesser hill chains. Between this Franconian and Swabian mountain system and the Rætian Alps of Austria there extends a vast level plain (southern Bavaria), bounded by the Danube to the N., the Iller to the W., the Inn and Salza to the E. The N. W. section of central Germany—always taking the Fichtelgebirge as the centre—appears like a labyrinth of hill chains, few of which, however, attain a considerable elevation. The more important of them are: the Werra mountains, the Habichts-Wald (Hesse-Cassel), the Eder hills, Egge hills, Rothhaar hills, the Haarstrang (Prussian Westphalia), the Westerwald, and Die Höhe or Taunus (Nassau). These are all situated between the Rhine on the W., the Main and Kinzig rivers on the S., the Werra on the E., and the Lippe on the N. The highest summit is the Astenberg in Westphalia.

lia, 2,536 feet high. To the N. of the Lippe only one other hill chain stretches in a N. W. direction nearly parallel to the Ems, viz., the Teutoburg forest, renowned in the history of Germany as the theatre of the conflict by which the rule of the Romans east of the Rhine was broken. East of the Weser the Weser hills run parallel to that river, while S. E. of them and N. of the Thuringian system the Hartz appears as an isolated mass of mountains, the highest summit of which (Brocken) reaches the height of 8,508 feet. On the left or western bank of the Rhine the northern spurs of the Vosges, extending into Rhenish Bavaria and Rhenish Prussia, are called the Haardt, the Hochwald, and the Hunsrück (1,800 to 2,000 feet high). Further N. the Ardennes send into Rhenish Prussia the ridge of the Eifel (1,800 feet high) and the Höhe Venn. 8. The great plain of northern Germany extends over the entire breadth of the country N. of a line drawn from the Holland and Oldenburg frontier to Osnaburg and Minden, thence E. S. E. to Leipzig, thence S. by E. to a point where the head waters of the Oder and Vistula approach one another. This vast plain, which at some former geological period has undoubtedly formed the bottom of the sea, is traversed only by two ridges of hills, none of which rise above 400 feet. One of these ridges extends from the lower Vistula W. to the Oder above Stettin; the other from Tarnowitz in Silesia S. of Breslau along the Oder to lat. 52° N., then a little to the N. of that parallel through the Prussian provinces of Brandenburg and Saxony into Hanover.—Each of the 3 seas by which Germany is bounded has a peculiar coast configuration. While the coast of the North sea or German ocean is largely indented by deep bays (Dollart and Jade bays) or wide embouchures (Weser and Elbe), and its "marshes" are the richest and most fertile soil in all Germany, the shores of the Baltic form many extensive lagoons (Haffs), and are generally uninviting and sterile. The shores of the Adriatic sea are steep cliffs and bluffs, with two excellent inlets, the bays of Trieste and Fiume, both of them of the utmost importance to the commercial interests of Germany. All together Germany has a coast line of 1,330 miles, viz.: 830 on the Baltic sea, 270 on the North sea, and 230 on the Adriatic. The advantages which the formation of the shores of the North sea would seem to offer to the development of the maritime interests of Germany, are to a great extent neutralized by the fact that a series of sand banks, called *Watten*, stretch nearly all along the coast. Beside this, the island which commands the entrance of all German ports on the North sea (Helgoland) has been ceded to Great Britain.—The diversified surface of Germany is intersected by many rivers. Their total number, not including the small creeks, is 500, 60 of which are navigable by nature and several others by means of slack water canals. The principal river systems are those of the Danube, Rhine, Weser, Elbe, and

Oder. The Danube, flowing from W. to E., has within Germany a length of 600 m., and its river system an area of over 72,000 sq. m. Its principal tributaries are on the left or N. bank, the Altmühl, Nab, Regen, and March; on the right bank, the Iller, Lech, Isar, Inn and Salza, Traun, Enns, and Leytha, all within the limits of Germany, beyond which it still receives the waters of the Mur, Drave, and Save. The North sea receives the river systems of the Rhine (over 500 m. within Germany, and with a territory of over 45,000 sq. m.), the Ems (235 m. in length, 5,000 sq. m. of territory), the Weser (377 m. and 17,500 sq. m.), and the Elbe (700 m. and 55,000 sq. m.). The principal tributaries of the Rhine are the Nahe and Moselle on the left bank; the Kinzig, Murg, Neckar, Main, Tauber, Lahn, Sieg, Wipper, Ruhr, and Lippe on the right. The Weser is formed by the confluence of the Werra and Fulda, and receives only a few tributaries (Werre, Aue, and Hunte on the left, Aller and Leine, Ocker, Wumme, and Geeste on the right). The Elbe has, next to the Danube, the largest river system. Its affluents are the Moldau, Eger, Mulde, Saale, Elster, Ohre, Aland, Jetze, Ilmenau, Schwinge, and Oste on the left bank, the Isar, Black Elster, Havel and Spree, Stecknitz, Elde, and Stör on the right bank. The territory drained by the rivers which flow into the Baltic sea has an area of 40,000 sq. m., of which two thirds belong to the system of the Oder (616 m. in length), and its numerous tributaries, the Oppa, Neisse, Weistritz, Katzbach, Bober, Welse, Ucker, and Peene on the left, the Ostrau, Olsa, Klodnitz, Malapane, Weide, Bartsch, Warta, Plöna, and Ihna on the right. Of the small river systems the following may be mentioned: the Eider (boundary between Germany and Denmark), 115 m. in length, with 4,000 sq. m. of territory; the Pomeranian rivers Rega, Persante, Wipper, Stolpe, Lapow, and Leba, with an aggregate territory of over 8,000 sq. m.; the Vistula, which in Germany has a length of only 55 m. and a territory of 620 sq. m.; the Adige (Etsch) and Isonzo, both emptying into the Adriatic sea (the Adige without, the Isonzo within Germany), and draining together an area of 8,000 sq. m. A number of canals connect several of the large river systems, but only a few of them can compare with the American canals. The most important is the Ludwigs canal, connecting the Danube with the Main (and through this with the Rhine), thus furnishing an uninterrupted navigation from the North to the Black sea. It has a length of 95 m. with 103 locks, and its cost of construction has been over \$4,000,000. The Bremervörde canal connects the Oste and Schwinge, tributaries of the Elbe; the Kiel canal connects the North and Baltic seas by the Eider, and the Stecknitz canal furnishes an outlet from the Elbe into the Baltic by the Trave; by the Finow and Mühlrose canal the river systems of the Elbe and Oder are connected.—The number of lakes in Germany is large, but most of them are inconsiderable. The following deserve to be

mentioned: the lake of Constance (Bodensee), the banks of which belong to 5 different states, Baden, Württemberg, Bavaria, Austria, and Switzerland; the lake of Garda, a small part of which only belongs to Germany; Achen lake, Tyrol; Zeller and Wolfgang lakes, Styria; Atter and Traun lakes, Austria; Staffell, Ammer, Würm, Tegern, Ohlert, and Königs lakes, Bavaria; Feder lake, Württemberg; lake of Steinhude (*Steinhuder Meer*), in Hanover and Lippe; Zwischenahner Meer, Oldenburg; the lakes of Plön, Kell, Seelent, Westen, and Grub, in Holstein; lake of Ratzeburg, Lauenburg and Mecklenburg; the lakes of Schwerin, Plau, Malchin, Flesen, Kalden, and Müritz, in Mecklenburg; Schwieloch and Scharmtz lakes, Brandenburg; the lakes of Madue, Damm, Papenzin, and Plön, Pomerania; Zarnovitz lake, in Pomerania and western Prussia; the Salt lake near Eisleben, in the Prussian province of Saxony; the lake of Laach, in Rhenish Prussia.—The climate of Germany is temperate, and, considering the extent of the country, remarkably uniform, the greater heat of the lower latitudes being tempered by the greater elevation of the country and its Alpine character. The limit of perpetual snow is in different parts of Germany from 7,300 to 8,000 feet above the level of the ocean. On the great plain of northern Germany the districts exposed to the moist W. and S. W. winds have a more inclement climate than central Germany; while the southernmost districts, though drier than the northern, have less heat than more northern latitudes. The average decrease of the mean temperature, going from S. to N., is 1° F. in 52 m., and going from W. to E. 1° F. in 72 m.; measured by the vertical elevation, it is 1° F. in 256 feet. The mean annual temperature of Goritz in Illyria (lat. 45° 56' N., long. 13° 37' 32" E.) is 59° F.; the mean temperature in summer 78.4°, in winter 37°. The mean annual temperature of Stralsund (lat. 54° 18' N., long. 18° 5' 32" E.) is 46.4° F.; the mean temperature in summer 68°, in winter 29.8°. The mean annual temperature of the valley of the Rhine is 52°, of Thuringia 47.5°, of Silesia 47°, of all Germany 48.8°. The extremes of temperature in the country N. of the Alps are 95° F. above and 81° below zero. In an average of 10 years the Rhine had been frozen over 26 days during each winter, the Weser 30 days, Elbe 62 days, Oder 70 days. The atmosphere is pure and wholesome, unfavorable to the development of endemic or hereditary diseases, except in the high Alpine valleys, where cretinism prevails. Epidemics generally appear in a less destructive form in Germany than in the neighboring countries. Of wild animals, the deer, hare, rabbit, fox, hamster (a kind of marmot peculiar to Germany), marten, badger, weasel, otter (rare), &c., are found nearly everywhere, stringent game laws preventing their destruction. Chamois, ibex, and bears are met with in the Alps, the last two rarely; wolves in the Alps E. of the Oder and W. of the Rhine. As to domestic animals, a good breed

of horses is raised in Mecklenburg, Holstein, and Hanover; cattle raising is a most important branch of husbandry in Oldenburg, the N. W. part of Hanover, Franconia, and the Alpine country; sheep are raised extensively in Saxony, Silesia, and Brandenburg; Saxony furnishes the finest quality of wool; goats, mules, and asses are reared principally in the mountainous districts of the south; hogs in all states, but chiefly in the west. Large birds of prey (the eagle and vulture) are rarely found beyond the Alpine districts; fowl of all kinds, wild and domestic, are plentiful in all parts of the country. The pheasants of Bohemia are celebrated; canary birds are raised in large numbers in Tyrol. Of amphibia Germany has only a limited number of species; of snakes there are only 2 venomous kinds, *vipera berus* and *V. chersea*. The different species of fish found in Germany number 110, of which 60 inhabit exclusively the ponds and lakes. Carp and pike are numerous in nearly all rivers and ponds, the salmon only in the larger rivers; sturgeon, cod, and sheatfish in the Elbe, trout in all mountain streams; herring and sardines in the Baltic and North sea. Oysters of good quality are obtained near the shores of Holstein, pearl muscels in some rivers of the interior. The silkworm is not raised on an extensive scale.—Germany is rich in mineral products, and mining has employed there a great number of persons from the remotest times. Gold is found only in a few places in limited quantities (in the Hartz mountains, Salzburg, and Tyrol), but silver abounds in the mountain ranges which diverge from the Fichtelgebirge in a N. E. direction, also in the Hartz mountains, in southern Westphalia and Styria. An extensive quicksilver mine, one of the largest in the world, is worked at Idria in Illyria. Copper is mined principally in Tyrol and Styria. Iron is found in large quantities in nearly all the mountain ranges; the best qualities are those worked in Styria, Westphalia, and Rhenish Prussia. Tin of an excellent quality abounds in Bohemia and the Erzgebirge; lead in Carinthia, Styria, Saxony, Bohemia, and Upper Silesia; calamine and zinc in Silesia; cobalt in Saxony. Salt is obtained in quantities more than sufficient for domestic consumption in all the states except Saxony, Nassau, and Anhalt. The production of coal has been enormously increased within the last 20 years. The most extensive coal beds occur in Rhenish Prussia, Westphalia, Upper Silesia, Saxony, Bohemia, and Styria. The N. W. districts have, instead, an abundant supply of peat for fuel. Sulphur, saltpetre, alum, vitriol, gypsum, chalk, ochre, emery, porcelain clay, graphite, marble, alabaster, and amber (on the shores of the Baltic) are found in larger or smaller quantities in different districts. Precious stones are comparatively scarce. Of mineral springs Germany possesses a great number, and several of them enjoy a world-wide reputation for their sanative virtues.—The soil of the country is, on the whole, only of moderate fer-

tility. If there are many tracts exuberantly productive, there are as many others almost as barren and sterile as the Russian steppes. Nay, a large portion of the northern level country would be less fertile even than they, if it had not the advantage of abundant rains. The most fertile tracts of land in Germany and in Europe are the marshes on the shore of the North sea. Rational agriculture has improved the natural condition of the soil in a high degree.—The vegetable kingdom numbers 8,418 species of phenogams (890 trees and shrubs, 2,170 perennial, 169 biennial, and 684 annual plants), and 4,806 species of cryptogams (78 ferns, 585 mosses, 112 liverworts, 2,490 fungi, 670 lichens, and 876 algae). All kinds of grain and fruit belonging to the temperate zone are raised in Germany: rye, barley, oats, potatoes, peas, and beans, everywhere; maize principally in the S.; wheat in the S. and W.; buckwheat in the N.; millet in the S. E.; rapeseed, poppy, anise, and cummin in the central and N. W. districts. The largest grain fields are in Württemberg, the smallest in Mecklenburg. Moravia, Bavaria, Württemberg, Saxe-Altenburg, Mecklenburg, Holstein, &c., produce a larger quantity of breadstuffs than is required for home consumption, while Tyrol, Lower Austria, Saxony, and some of the Saxon duchies are importers of breadstuffs. Flax and hemp, madder, woad, and saffron are cultivated more in the S. and central region than in the N. Tobacco is extensively raised (even for exportation to other tobacco-growing countries) on the upper Rhine, the Werra and Oder, and in Brandenburg. Hops of an excellent quality are furnished by Bohemia, Bavaria, and Brunswick. Beets are used in enormous quantities for the manufacture of beet sugar, and their cultivation has almost entirely superseded the grain culture in the Prussian province of Saxony, Anhalt, Hesse-Darmstadt, S. Bavaria, and Bohemia. Chicory, as a substitute for coffee, is raised in the country between the Elbe and Weser rivers. In garden culture Württemberg, Bavaria, Hesse, and the Saxon duchies hold the highest rank. The fruit raised on the banks of the Rhine and Neckar, in Saxony and N. W. Bavaria, is of the very best quality to be found anywhere. Peaches and figs ripen only in localities protected from the cold. The apples of Bohemia and Saxony are of the choicest kind, and are exported to Russia in large quantities. Marron chestnuts, almonds, &c., are raised in the S. W. states; oranges, figs, pomegranates, lemons, &c., only in Tyrol and Illyria. Great attention is paid to the improvement of fruit. In all the states there are pomological societies, which from time to time hold national conventions. The culture of the vine extends to lat. 51° 30' N.; the best wine-growing districts are the valleys of the Rhine and Danube, Neckar, Main, and Moselle. The best qualities are raised in the district between Mentz and Bingen on the right bank of the Rhine (Johannisberger, Steinberger, Geisenheimer, Hattenheimer, Hochheimer—ab-

breviated in English, Hock—and Rüdesheimer), in the grand duchy of Hesse (*Liedfrauen-Milch* at Worms and Niersteiner), and in the Palatinate (Forster, Deidesheimer, Dürkheimer). In the valley of the Main the Würzburg wines are equal to the best qualities of Rhine wine. Lighter wines of a good quality are raised in the valleys of the Moselle, Aar, and Neckar, also in Bohemia (Melniker and Aussiger), in Moravia, Styria, and Tyrol. A very inferior quality is raised in Saxony (Meissen and Naumburg) and in Silesia (Grünberg). Altogether the vineyards of Germany cover an area of nearly 510,000 acres, and the value of the crop in favorable seasons comes near \$25,000,000. The physical culture of Germany is highly developed, and inferior only to that of England. The products of agriculture have been nearly doubled by the introduction of more rational methods of cultivation since 1816. All German states possess agricultural colleges, some of which enjoy a world-wide reputation. The methods of cultivation are, however, different in different portions of the country. The triennial and quadrennial rotation of crops are most in use. According to the first method, winter grain is raised in the first year, spring grain in the second, and potatoes, pulse, or fodder in the third year; according to the second method, recommended by Thäer, a grain crop is always followed by a crop of fodder or pulse. In some of the northern states crops of grain are raised upon a certain portion of the farm for several successive years, after which the field is allowed to lie fallow for 8 to 7 years according to the number of lots into which the farm is divided. In Mecklenburg agriculture approaches to horticulture, inasmuch as many different kinds of fruit are raised on little plots of ground, one by the side of another.—The culture of forests is carried on in Germany on a more scientific basis than in any other country. Having in former times thoughtlessly wasted their wealth in forests, many German states have been compelled to replant them in order to satisfy the wants of agriculture and industry. In many states the forests mostly belong to government, and are as carefully kept as gardens; but even private owners are prohibited by law from wasting their forests without regard to the public good. The most extensive forests are found in central and southern Germany and in the eastern provinces of Prussia. The entire superficies of woodland in Germany is 88,500,000 acres, of which Austria has 16,000,000, Prussia 10,200,000, Bavaria 5,400,000, Hanover, Württemberg, and Baden about 1,250,000 each.—Of all European countries, Germany has the oldest manufactures. Within the last century it has fallen in regard to the extent of its mechanical pursuits behind England and Belgium, but within 20 or 30 years it has advanced rapidly, and is now in a fair way to recover its former position. As early as the 18th century Germany was celebrated for its cloth and linen manufacture, its glass wares, carved and chis-

elled wares, &c. In the 14th century the silk manufacture was introduced, and the first paper mill was established as early as 1390. During the 15th century Germany became celebrated for its watch manufacture. Printing works were established at Augsburg and the lace manufacture introduced into Saxony in the 16th century. At that time Germany was to Europe, in regard to industry and commerce, what England is now. The 80 years' war destroyed all prosperity for a long time. At the beginning of the 18th century German industry again flourished, principally in consequence of the immigration of the Huguenots expelled from France. Frederic II. of Prussia and Joseph II. of Austria strove to raise it to its former eminence, but the French revolutionary wars blighted it once more. Since then it has recovered the lost ground, principally by means of the *Zollverein*, a commercial union of the majority of states (without Austria), by which free commerce is established among all its members, while a high tariff protects their industry against foreign competition. The progress made by Germany under this system is truly remarkable. While 40 years ago it had preëminently become an exporter of raw products of the soil, it is now one of the principal exporters of industrial products and importers of raw materials. The centres of German industry are the kingdom of Saxony, Westphalia and Rhenish Prussia, Moravia, and Bohemia. The linen manufacture stands highest in Saxony, Silesia, and Rhenish Prussia. Cotton mills are numerous in all the *Zollverein* states. They required in 1858 1,109,190 cwt. of raw cotton and 577,527 cwt. of cotton yarn. The German provinces of Austria had in 1857, 164 cotton mills with 1,408,752 spindles. How the woollen manufacture of Germany has been increased by the *Zollverein* may be seen from the fact that in 1825 Germany exported to England alone 280,000 cwt. of raw wool, while in 1851 the quantity of woollen yarn imported into Germany amounted to 340,000 cwt., and the quantity exported to 90,000 cwt., leaving not less than 250,000 cwt. as the net import of raw material. In the same year the quantity of woollen cloth exported amounted to 120,000 cwt. The German silk fabrics equal in quality the French and English, but are somewhat inferior in design. The principal silk manufactories are in Prussia (Berlin, Elberfeld, and Crefeld), Austria (Vienna and Styria), and Saxony. The export of silk fabrics from Germany is nearly equal in amount to the domestic consumption. The paper manufacture has made considerable progress, although the finest qualities are still imported to some extent. Thirty years since Germany supplied the world with rags, and imported paper; in 1851 the net import of the former was 370,000 cwt., the net export of the latter 35,000 cwt. In some fabrics of wood, as the choicest kinds of cabinet furniture (Berlin and Vienna), and all kinds of toys, Germany stands unequalled, and is a large exporter to all countries of the world. The iron

manufacture has of late increased rapidly. In 1854, 2,193,889 cwt. of iron were mined in Prussia, and 3,881,169 cwt. in 1857, an increase in 4 years of 44 per cent. Still the consumption has increased in a higher ratio, there having been imported, in 1854, 2,650,308 cwt., and in 1857, 4,793,486 cwt., an increase of 80 per cent. The best iron and steel wares are manufactured in Rhenish Prussia, Saxony, Bohemia, and Styria. The machine shops of Prussia, Saxony, Bavaria, Baden, and Austria rival, if they do not excel, the largest establishments of their kind in England. In 1858 a machine shop at Berlin, established in 1837, turned out its 1000th locomotive. Other important branches of industry are gold and silver wares (Augsburg, Vienna, and Berlin), glass wares (Bohemia and Silesia), leather (Rhenish Prussia), porcelain (Saxony, Vienna, and Berlin), musical instruments (Vienna), geometrical and astronomical instruments (Munich, Vienna, and Berlin), clocks (Baden), &c. Brewing is one of the most extensive branches of industry, especially in Bavaria. The manufacture of beet sugar has increased wonderfully within the last 20 years. There were on May 1, 1857, in the *Zollverein* states, 232 beet sugar manufacturing establishments, which during the 9 months preceding had made 1,800,000 cwt. of sugar from 23,421,179 cwt. of beets. At the same time the Austrian provinces had about 50 establishments, producing 360,000 cwt. of sugar.—The foreign commerce of Germany is of great importance, the total value of the imports and exports being estimated at about \$800,000,000 per annum. To give exact figures is impossible, since the official tables of the two largest territories, the *Zollverein* and Austria, include the non-German provinces of Prussia and Austria respectively, and no trustworthy statements exist in regard to some of the smaller territories. Beside the Prussian customs union, which includes 26 states, and the Austrian (Austria and the principality of Liechtenstein), the following states have each different tariffs: Holstein-Lauenburg (incorporated into the Danish customs territory), the two grand duchies of Mecklenburg, Limburg (to Holland), and the Hanse towns Hamburg, Bremen, and Lübeck. The latter, with Trieste on the Adriatic sea, are the principal outlets of German commerce. Hamburg holds the third rank of all European ports, London and Liverpool only being superior to it. In 1856 the aggregate value of its imports and exports was, seaward, \$183,000,000, landward, \$193,000,000; but in this statement a large portion of the imports into Hamburg from Germany figures also among the exports to foreign countries, and *vice versa*. The value of goods exported of Hamburg manufacture exceeded in the same year \$10,000,000. Next follows Trieste, with an aggregate export and import in 1856 of \$120,000,000, and Bremen, over \$100,000,000. Lübeck, Stettin, and Altona are less important. Altogether the commerce of these ports is now 5 times as large as in 1816. The shipping of Germany, though large in numbers (over 15,000

vessels), is small in tonnage, the average being not more than 52 tons for each vessel. The principal articles of export are wool, hops, grain, cattle, linen yarn, skins and hides, glass ware, and antimony, to England; iron and steel wares, zinc, coal, lumber, hops, hemp, flax and seed, alcohol, and cattle, to France; grain, timber, coal, wine, leather, wool, metals, woollen and cotton fabrics, hosiery, hardware, china and glass ware, to Holland; wool, wine, and salt, to Belgium; grain, salt, and brandy, to Switzerland; seeds, fruit, preserves, and sugar, to Sweden and Russia; linen and cotton goods, ribbons, and hosiery, to Italy, Spain, and Portugal; wine, cotton, woollen, linen, and silk goods, hardware, glass ware, toys, &c., to America. The imports are, beside all kinds of raw materials (cotton, pig iron, copper, hemp, tallow, hair, bristles, potash, &c.), coffee, sugar, rice, wine (from France and Hungary), cloth, laces, coal, machines, the finer qualities of silk fabrics, jewelry, &c. The domestic commerce of the German states is by no means less important than the foreign, but no accurate statistical tables in regard to it can be obtained. The principal marts are Leipsic, Frankfort-on-the-Main, Frankfort-on-the-Oder, and Brunswick. The monetary centres are Frankfort-on-the-Main, Vienna, Berlin, Augsburg, and Hamburg. The silver standard prevails in Germany. The unit in the northern states is the *Thaler* (80 thalers to 1 Zollverein pound of silver, equal to 1.889 lb. avoirdupois); in the western the *Gulden Rheinisch* (52½ to 1 pound of silver); in Austria the *Gulden* (45 to 1 pound of silver). The gold coins common to all Germany are the crown (50 to 1 pound of fine gold), and the half crown. Their value is regulated by commerce, and averages about 9½ thalers (\$6.58) the crown. —In 1858 Germany had 6,752 m. of railroad, viz.: Prussia (including the non-German provinces) 2,640 m., Austria 1,173 m., Bavaria 759, Hanover 450, Saxony 850, Baden 240, Hesse-Cassel 205, Württemberg 177, Holstein 158, Mecklenburg-Schwerin 182, Hesse-Darmstadt 108, Brunswick 71, Anhalt 66, Saxe-Weimar and Nassau 44 each, Saxe-Coburg-Gotha 28, Saxe-Altenburg 20, and the remaining states less than 20 each. The capital invested in the roads (stocks and bonds, and appropriations of the different governments respectively) amounted to \$610,000,000. Their aggregate earnings in 1856 were \$56,700,000; and they carried in that year 41,500,000 passengers and 20,000,000 tons of freight. The number of locomotives in 1857 was 2,568, of which 1,978 were built in Germany, 308 in England, 177 in Belgium, 73 in the United States, and 22 in France. The length of macadamized turnpike road in Germany exceeds 85,000 m. Regular steamboat lines are established on the 6 principal rivers, the Rhine (since 1827), Danube (since 1833), Elbe, Weser, Main, and Moselle. Steamships ply regularly between the ports on the Baltic and North seas, and various British, Danish, Swedish, and Russian ports. There are two

transatlantic lines of steamers, the Hamburg line, with 5 ships, and the North German Lloyd at Bremen, with 4 ships. Trieste is connected by a numerous fleet of steamers with all Mediterranean ports.—The Christian religion is professed by all inhabitants of Germany, the Jews only excepted. Roman Catholicism is professed by 52½ per cent. of the total population, Protestantism by 46½ per cent. of the total, or 55 per cent. of the purely German population. The Roman Catholics are, in Austria, 97 per cent., in Bavaria 71, in Rhenish Prussia 70, in Baden 65, in Silesia 56½, in Westphalia 54, in all the German provinces of Prussia 85½, in Hesse and Württemberg over 80 per cent. of the population. The Protestants (divided into Lutherans and German Reformed church, or united under the name of Evangelical church) number in the German provinces of Prussia 8,370,000, or 63 per cent. (42 per cent. of the aggregate total of Protestants in all Germany); in Saxony near 2,000,000, or 97 per cent. of the population; in Hanover near 1,600,000, or 89 per cent. The Dutch Reformed church, Baptists, and other dissenting denominations, have about 20,000 professors, Moravians 9,000, German Catholics and Free congregations about 25,000.—Public education in Germany is more general than in any other country, with the exception of some of the states of the American Union. There are 24 universities (Berlin, Bonn, Breslau, Erlangen, Freiburg, Giessen, Göttingen, Grätz, Greifswalde, Halle, Heidelberg, Innsbruck, Jena, Kiel, Königsberg, Leipsic, Marburg, Munich, Otmütz, Prague, Rostock, Tübingen, Vienna, Würzburg), beside a number of theological colleges, agricultural colleges (Eldena, Jena, and Tharand), academies of veterinary surgery, a mining academy (Freiberg), polytechnical institutes (Berlin, Munich, Dresden, Brunswick, &c.), altogether with 1,600 professors and lecturers and about 16,000 students (1 to 2,746 inhabitants). Of gymnasia (colleges) there are over 400. Normal schools, academies of commerce, technology, navigation, grammar schools, private academies, institutions for the blind and for deaf mutes, are numerous. As to common schools, they are more general than in any other country. In nearly all German states the attendance of all children at school for a term of at least 5 years is made compulsory by law; and in some states, especially in central Germany and in Württemberg, those who are unable to read and write are very rare exceptions indeed. In Prussia there are only 2½ per cent. of children between 7 and 15 years of age who do not attend school (in Bavaria 20, in Austria 28, in France 44 per cent.). Nearly all the capital cities have large public libraries, museums of art, scientific collections, &c. The royal library of Munich contains 800,000 volumes and 20,000 manuscripts, the royal library of Berlin 500,000 volumes, the imperial library of Vienna 850,000 volumes and 20,000 manuscripts, the royal library of Dresden 800,000 volumes and 2,800 manuscripts, and the university library of Göttingen 800,000 volumes and 5,000 manuscripts. Beside

these, there are at least 12 libraries containing each over 100,000 volumes. Anatomical and mineralogical museums, zoological and botanical gardens, observatories, &c., are connected with most of the universities. The number of associations of scholars in all different sciences is very great. The fine arts are as carefully fostered as science. Not even Italy is ahead of Germany in musical composition, many of the greatest composers of modern times being Germans, as Handel, Gluck, Mozart, Beethoven, Weber, Haydn, Meyerbeer, and Mendelssohn. In the art of painting the members of the two principal German schools, of Munich (Cornelius, Kaulbach), and of Düsseldorf (Schadow, Leasing), rival the best artists of all times. In sculpture Rauch, Dannecker, and Rietschel take rank with Thorwaldsen and Canova. German literature is exceedingly prolific, and contains a very great number of works of sterling merit. The periodical press of Germany stands, in regard to the number and intrinsic value of publications, below that of England, and perhaps of the United States. Still it has made considerable progress since 1848. The largest and most influential newspapers are the *Allgemeine Zeitung*, Augsburg; *Kölnische Zeitung*, Cologne; *Deutsche allgemeine Zeitung*, Leipzig; *Ostdeutsche Post* and *Wiener Zeitung*, Vienna; *Vossische, National-, and Volks-Zeitung*, Berlin; *Weser-Zeitung*, Bremen; *Hamburger Nachrichten*, Hamburg; *Zeitung für Norddeutschland*, Hanover; *Nürnberger Courier*, Nuremberg; *Der Schwäbische Mercur*, Stuttgart; *Frankfurter Journal* and *Oberpostamtliche Zeitung*, &c.—Politically Germany is divided into 85 states, of which 81 have a monarchical and 4 a republican form of government. Two of the monarchies, Austria and Prussia, belong to the great powers of Europe, and possess large territories without the limit of Germany; while two of the German states are subject to non-German rulers (Holstein with Lauenburg to the king of Denmark, Luxemburg with Limburg to the king of Holland). The states of Germany are: 1 empire, Austria; 5 kingdoms, Prussia, Bavaria, Saxony, Hanover, and Würtemberg; 1 electorate, Hesse-Cassel; 7 grand duchies, Baden, Hesse-Darmstadt, Luxemburg (with Limburg), Mecklenburg-Schwerin, Mecklenburg-Strelitz, Saxe-Weimar, and Oldenburg; 8 duchies, Holstein (with Lauenburg), Brunswick, Nassau, Saxe-Meiningen, Saxe-Coburg-Gotha, Saxe-Altenburg, Anhalt-Desau-Köthen, and Anhalt-Bernburg; 9 principalities, Schwarzburg-Sonderhausen, Schwarzburg-Rudolstadt, Lippe-Deimold, Schaumburg-Lippe, Waldeck, Reuss senior, Reuss junior, Hesse-Homburg, and Liechtenstein; 4 free cities, Lübeck, Frankfurt, Bremen, and Hamburg. Of Austria, only the two archduchies of Austria proper, Styria, Salzburg, Carinthia, Carniola, the Littoral, Tyrol, and Vorarlberg, Bohemia, Moravia, and Silesia form part of Germany; of Prussia, only the Rhenish province, Westphalia, Hohenzollern, the province of Saxony, Brandenburg, Pomerania, and Silesia. (For a comparative table of area

and population, see EUROPE.) Germany is a loose confederation (*Bund*) of sovereign states, founded upon an act of the congress of Vienna, June 8, 1815, and a statute agreed upon, May 15, 1820. The original object of the confederation was simply the preservation of the territory of, and law and order in, the different states. Hence it has been argued that the confederation was of a purely defensive character, and could not in any case assume an aggressive position without endangering the European balance of power. But the 37th section of the supplementary statute of 1820 confers upon the Bund ability to wage war against a foreign power, not only when an invasion has actually taken place, but also when the frontier of Germany seems to be endangered. It was upon the ground of this clause that Austria claimed the assistance of the Bund in her war with France and Sardinia in 1859. The administration of the Bund rests with the diet (*Bundestag*, or *Bundesversammlung*), which consists of representatives appointed by the several governments without any concurrence of the people. The diet is a most awkward and unwieldy machine, since its members are bound in every vote to comply with distinct instructions from their governments. The chairmanship is vested in Austria. In all questions pertaining to the general organization of the Bund, the whole number of votes is 69, of which 4 are cast by Austria and each of the 5 kingdoms, 8 by Baden, Hesse-Cassel, Hesse-Darmstadt, Holstein, and Luxemburg, 2 by Brunswick, Mecklenburg-Schwerin, and Nassau, and 1 by each of the remaining states, including some which have been united with others since the foundation of the Bund. When going into executive committee, the diet has only 17 votes, of which 11 are cast by Austria, the 5 kingdoms, Baden, the two Hesses, Holstein, and Luxemburg; while of the remaining 6 votes each is cast by a number of the petty states collectively. The diet meets at Frankfurt, and is recognized as an independent power; but it has never yet sent ambassadors abroad to represent the German confederation, though several foreign ministers are accredited near it. During 40 years of its existence, the diet has confined its labors almost exclusively to the centralization of repressive measures against all popular movements. The most important feature of the confederation—its military organization—has never yet been tested by actual experience. The army of the confederation is to consist of the quota (*Contingente*) of the different members (1 per cent. of the population, beside $\frac{1}{2}$ per cent. for the reserve), numbering altogether 470,000, not including the reserve forces; but this number is considerably exceeded. One-eighth of the total number is to consist of cavalry, and 2 guns are to be furnished with every 1,000 men. The fortresses belonging to the confederation, and to be garrisoned by the federal army, are Mentz, Luxemburg, Landau, Ulm, and Rastadt. The army is divided into 10 *corps d'armée* and 1 division of in-

fantry reserves. The first 8 corps are furnished by Austria (in 1855, 158,800), the 4th, 5th, and 6th by Prussia (170,500), the 7th by Bavaria (50,200), the 8th by Württemberg, Baden, and Hesse-Darmstadt (47,500), the 9th by Saxony, Hesse-Cassel, and Luxembourg (85,800), the 10th by Hanover, Brunswick, Holstein, the two Mecklenburgs, Oldenburg, and the three Hanse towns (49,900), and the division of infantry reserves by the remaining 16 petty states. The total number in 1855 was thus 525,000 (404,500 infantry, 71,150 cavalry, 40,200 artillery, 5,700 engineers, &c., 16,800 teamsters, &c.), with 1,122 pieces of ordnance. In 1856 the number had increased to 560,000. Yet even this is not one-half of the entire military force which Germany is able to wield. The armies of the different states are far greater than their quota to the army of the confederation. The army of Austria alone, including her non-German provinces, upon the war footing, exceeds 700,000 men, with 1,844 pieces of ordnance; and that of Prussia, including both classes of the *Landwehr*, 541,000 men, with 1,004 pieces of ordnance. Thus, Austria and Prussia united with all Germany would be able to muster nearly 1,500,000 soldiers. But if formidable, when united, on land, Germany is utterly powerless on the sea. It has no navy at all. In 1848 an attempt was made to establish one by voluntary contributions of the people, but it was one of the first acts of the diet, when resuscitated, to sell the small squadron at auction, in 1852, and to destroy all vestiges of its existence.—Of the earliest history of Germany no records remain. The Romans, before the time of Julius Cæsar, knew little or nothing of the people living E. of the Rhine and N. of the Danube, though some German tribes had invaded the Roman empire toward the end of the 2d century B. C. At the time of the conquest of Gaul (France), the Romans learned that the country beyond the Rhine contained a numerous people, who, although barbarians according to the standard of civilization of that time, had fixed settlements and were agriculturists. They were called Germani, either, as Strabo asserts, because they were nearly related—brothers german—to the inhabitants of Gallia, or, which is more probable, from the weapons they carried (*ger*, spear, *guerr*, war, *Heer*, host, or *Wehr*, arms). If the latter theory is correct, Germans would mean spear men or warriors. They were tall, light-haired, blue-eyed, warlike, and fond of independence, intoxicating liquors, and games, in which they often staked their personal liberty. Their chief occupations were hunting, care of cattle, and the use of arms. They were divided into nobles, freemen, and serfs. They paid peculiar respect to their women and the aged, and honored chastity not less than valor. They elected their chiefs, whom the Romans often call kings. They had priests, bards, and sacred groves, and worshipped or feared gods, demigods, and giants. Woden and his wife Fria or Frigg, Ziu, and Fro, were among their chief divinities. They be-

lieved in the immortality of the soul, or in life in Walhalla. Their sacrifices consisted of domestic animals, including horses, and sometimes of human victims. They had no cities, but mostly lived in hamlets, or small communities, which held several species of property in common. They were divided into more than 50 tribes, of which the following principally (though not simultaneously) figure in the history of the Romans: the Teutons, Ubii, Chauci, Catti or Chatti, Ruggi, Varni, Batavi, Usipetes, Tencteri, Bructeri, Angrivarii, Tribocci, Cherusci, Longobardi, Suevi, Goths, Marcomanni, Hermunduri, Burgundians, Narisci, Vandals, Gepids, Franks, and Alemanni. These tribes did all live within the limits of the Germania proper of the Romans, which was bounded by the North sea and the Baltic, the Elbe, Danube, and Rhine. The districts S. of the Danube and W. of the Rhine, which became Roman provinces under the names of Rætia, Vindelicia, and Noricum, and Germania Prima and Secunda (in Gaul), were mostly inhabited by non-German tribes, and often exposed to the incursions of the Germans. One of these incursions was headed by Ariovist, who was driven from Gaul by Cæsar, in the first year of his Gallic campaigns. Cæsar and the generals of Augustus nominally subjected Germany; but when the Romans attempted to convert their nominal dominion into real possession of the country, they were ignominiously defeated, and Germany was liberated by the chief of the Cheruscan tribe, Arminius, or Hermann, A. D. 9. The subsequent expedition of Germanicus was of little avail. From that time the history of Germany is in part lost in vague traditions and in part connected with the history of the Roman empire for several centuries, until the country, over which the whole torrent of the great migration of nations had swept, became gradually united with the great Frankish empire of Clovis (481–511) and his successors. Among these Charlemagne, or Karl the Great (771–814), consolidated the empire by subjecting the Saxons, the last German tribes who had, until then, succeeded in maintaining their independence. Charlemagne's rule extended from the Ebro in Spain to the Elbe in the N. E., the Raab (Hungary) in the S. E., and beyond the Po in Italy. He compelled the Saxons to become Christians, but at the same time he introduced among them an institution any thing but beneficial or congenial to them, viz.: a feudal aristocracy and a strong temporal power of the clergy. The contest between these and the royal power fills the history of Germany for long centuries. The feeble successor of Charlemagne was unable to keep the vast empire together. In 843 it was divided between his 3 sons, Italy falling to the share of Lothaire, France to Charles the Bald, and Germany to Louis. The German kingdom was at that time bounded W. by the Rhine, E. by the Elbe, the Saale, and the Bohemian forest, and S. by the Danube. The sons of Louis subdivided Germany into 8 lesser kingdoms, but these were reunited by Charles, and for a brief

time even France was once more joined to Germany (882-887). Arnulf, a nephew of Charles, was elected German king, and was succeeded (899) by his son Louis, surnamed the Child, with whom the Carolingian dynasty became extinct (911). Germany at that time consisted of a number of great territories (duchies), the rulers of which, together with their most powerful vassals, elected the king, whose power, however, depended very much upon the good will of the dukes. The Franconian, Conrad I. (911-918), unsuccessfully endeavored to make his authority respected by the mighty Saxon duke Henry, and on his deathbed entreated his subjects to elect his own adversary. Henry I. (919-936) restored the empire by victories over the Danes, Slavi, and Magyars. His son, Otho I. (936-978), extended the boundaries beyond the Elbe and Saale rivers, defeated the Magyars, who had invaded the country, so completely that they never afterward ventured to return (955), and conquered Lombardy. From that time the conquest of Italy became one of the principal aims of nearly all rulers of Germany. For many of them the barren honor of being crowned by the pope emperor of the Roman empire became the chief object of all their desires, to obtain which they allowed their royal power in Germany to be encroached upon more and more by the vassal princes. The Saxon dynasty ruled until 1024 (Otho II. 973-983, Otho III. 983-1002, Henry II. 1002-24), and was succeeded by the Franconian. Conrad II. (1024-'39), an energetic and well-meaning man, conquered Burgundy for the German empire. His son, Henry III. (1039-'56), extended the German influence over the Slavic countries and Hungary, and succeeded for a time in maintaining the royal authority against all attacks of the aristocracy and hierarchy. But the youthful Henry IV., who ascended to the throne in 1056, was unable to resist the power of the papacy, then at its zenith under Gregory VII., and was obliged to yield some of the most important prerogatives of the crown. His son, Henry V. (1106-'25), was the last ruler of the Franconian dynasty. After the brief reign of Lothaire II., the dynasty of the Hohenstauffen (Swabians) succeeded to the throne, and gave to the country 5 kings: Conrad III. (1138-'52), Frederic I. (1152-'90), Henry VI. (1190-'97), Frederic II. (1215-'50), and Conrad IV. (1250-'34). Between Henry VI. and Frederic II., Philip of Swabia and Otho IV. of Brunswick reigned as rival kings, and after the death of Philip Otho alone. The two first of the Hohenstauffen represent the most glorious period of German history during the middle ages. Frederic I., surnamed *Barbarossa* (*der Rothbart*), figures in the popular songs and traditions of Germany as the ideal emperor, the representative of German national power and splendor, who, according to the popular legend, is not dead yet, but only asleep in a cave under the Kyffhäuser mountain, whence he will arise once more in all his might, to restore the empire in its former glory. The conquest of Italy and the attempt to break the tem-

poral power of the pope were the great objects of the Hohenstauffen emperors. After a gigantic struggle, lasting nearly a century, they succumbed. From 1250 to 1273 anarchy prevailed in Germany. Several rival kings were elected (William of Holland, Richard of Cornwall, Alfonso of Castile, and Henry Raspe), but none of them obtained any authority. At last, in 1273, Count Rudolph of Hapsburg was elected king, and, by vigorously suppressing the feuds of the knights and barons, succeeded in reestablishing at least the semblance of royal authority. At the same time he was successful in obtaining for his family several important territories (Austria, Styria, Carinthia, Carniola, and Tyrol). After his decease (1291) Adolph, count of Nassau, was elected king by the dukes, who were jealous of the growing power of the Hapsburgs; but Albert, Rudolph's son, wrested the crown from him (1298-1808). Under Albert's reign the Swiss cantons declared their independence of Austria. His successors were Henry VII. of Luxemburg (1308-'13), Louis IV. of Bavaria (1313-'47), Charles IV. of Luxemburg (1347-'78), who by a sort of written constitution (golden bull) defined and increased the power of the prince electors, Wenceslas or Wenzel (1378-1400), so miserable a ruler that it was found necessary to dismiss him, Rupert of the Palatinate (1400-'10), and Sigismund, brother of Wenceslas. During the reign of the latter the attempt of Huss to reform the doctrines of the church was the principal event. Huss was burned at the stake, at the council of Constance (1415), the emperor having ignominiously broken his pledge to protect him during his stay at Constance. This treachery provoked the bloody war of the Hussites. After Sigismund's decease (1437), the royal or imperial crown of Germany (the title of Roman emperor having gradually supplanted that of German king) remained continuously with the Hapsburg family. The energetic and liberal Albert II. (1438-'40) was succeeded by the inert and feeble Frederic III. (or IV., as Frederic the Fair, the rival of Louis the Bavarian, had borne the title of king, as Frederic III.), who bore the royal title for more than half a century (1440-'93). His son, Maximilian I. (1493-1519), a chivalrous man of noble impulses, but lacking perseverance, organized the empire more systematically than had ever before been attempted, but was unsuccessful in his efforts to establish a national army. Under his reign the reformation of the church was begun by Luther (1517). Once more Germany became the ruling power of Europe under Charles V., grandson of Maximilian, who united the crowns of Spain, the Netherlands, Germany, and Naples, and vigorously opposed the efforts of France to obtain the control of Italy. But even during his reign the germs of civil and political dissension contained in the reformation of the church began to be developed in Germany. A formidable insurrection of the peasants, who longed for civil as well as religious liberty, was quelled with difficulty by the princes under the

sanction of Luther, who was only too anxious to scout the idea of an amelioration of the political condition of the people. The Protestant princes of northern Germany leagued themselves against the imperial authority, and though Charles defeated them (1547) by the aid of Maurice of Saxony, he was compelled by his former ally to grant important privileges to the Lutheran church (1552). In the mean time the 8 bishoprics of Toul, Metz, and Verdun had been wrested from the German empire by France. Disgusted with the successes of his adversaries, Charles resigned the crown. He was succeeded by his brother Ferdinand I. (1558-'64). The imperial authority was rapidly sinking to utter insignificance. France in the west and Turkey in the east were hovering on the borders of Germany, ready on every occasion to foster the internal dissensions of the empire and to conquer from it valuable possessions. The feeble Maximilian II. (1564-'76), the visionary Rudolph II. (1576-1612), and his brother Matthias (1612-'19), were unable to stem the political decay. The 30 years' war (1618-'48), which devastated and impoverished Germany, destroying all industry and commerce, left the imperial authority completely shattered, and Germany cut up into a multitude of petty states, the rulers of which were absolute monarchs in fact, if not in name. The horrors perpetrated by the monarch Ferdinand II. (1619-'37) against his Protestant subjects were unparalleled since the days of Genghis Khan. The peace of Westphalia (1648) concluded by Ferdinand III. (1637-'57) tore Alsace from the German empire. Under the pedantic and feeble-minded Leopold I. (1658-1705) Germany took part in the coalition against the rising power of France, but, although successful in war, did not obtain any signal advantages by the peace. From that time the title of German emperor appeared only as an empty surname of the rulers of Austria (Joseph I., Charles VI., Francis I., the husband of Maria Theresa, whose enemy, Charles Albert of Bavaria, was also crowned as Charles VII., &c.). In fact, Germany was merely a maze of almost numberless little despotisms, among which a few larger states were endeavoring to obtain a voice in the councils of Europe. Prussia was successful, through the genius of Frederic the Great, in establishing a great Protestant power, able to cope with Austria, but at the same time anxious to prevent the reconstruction of a great united empire. Thus the attempts of the emperor Joseph II. (1765-'90, or rather 1780-'90, when he reigned himself) to reestablish the imperial authority in southern Germany were baffled by Prussia. At last the tempest of the French revolution prostrated the tottering ruin of the German empire. Vanquished by the armies of France, the emperor Francis II., son and successor of Leopold II. (1790-'92), ceded by the treaties of Campo Formio (1797) and of Luneville (1801) the country on the left bank of the Rhine. The petty rulers who lost their possessions in this way were indemnified

by the territories of ecclesiastical princes. In 1805 several states seceded from the empire and became allies of France; and when at last, in 1806, a number of German states formed the Rhenish confederation under the protectorate of Napoleon, the emperor Francis resigned the German crown, and the empire was formally dissolved. A number of the smaller territories were annexed to the larger states, and most of the free cities, which, under the nominal authority of the emperors, had enjoyed a sort of republican government, lost their independence. The efforts of Prussia to oppose to this confederation a north-German league having been frustrated, nearly the whole of Germany, with the exception of Austria and Prussia, was reduced to a state of French vassalage. The minions of the emperor Napoleon ruled the country with an iron rod, and if they removed many of the most glaring remnants of feudal despotism, they introduced in their stead all the horrors of an irresponsible military régime, and carried their extortions to a frightful extent. The sums drawn from Germany by Napoleon under the designation of contributions or subsidies must be counted by hundreds of millions. The independence of the country was reestablished by the coalition of Austria, Russia, Prussia, Sweden, and Great Britain (1812-'15). A reconstruction of the old empire having been rendered impossible by the position which Prussia had assumed, a confederation was formed by all those states which had contrived to maintain their sovereignty during the Napoleonic troubles (June 8, 1815). Their number, which had exceeded 300 at the time of the dissolution of the empire, had then been reduced to less than 40, and a further reduction has since then taken place by the extinction of several petty dynasties. The enthusiastic hope of the German people that Germany would once more appear as a powerful united nation was sorely disappointed. No national representation was to give stability, upon a popular basis, to the confederation. The diet being only a permanent convention of the representatives of princes, all jealous of their individual sovereignty and unwilling to recognize the claims of the nation, became an abject tool of political oppression, and a harmonious coöperation of the states existed only in regard to repressive measures against all progressive movements. Whenever the people of a single state endeavored to obtain free institutions, the diet found occasion to interfere in favor of absolute monarchical power. None of the promises contained in the act of confederation in regard to a general tariff legislation, a common currency and postal system, &c., were fulfilled. Whatever was attained in this respect was due to the efforts of single states. Thus the Prussian Zollverein united a large portion of the German states on the basis of common material interests, and, by the great advantages it secured to its members, kept alive the longings for a still more complete national union. The French revolution of 1830

found an echo in some of the smaller German states, the rulers of which were compelled to grant written constitutions to their subjects. A vigorous political life began to be developed in the S. W. states, and after the accession to the Prussian throne of Frederic William IV. (1840), in northern Germany also the demands of the people became more distinctly defined, while in Austria all popular aspirations were suppressed by the despotic rule of Prince Metternich. Immediately upon the downfall of the Orleans dynasty in France (Feb. 24, 1848), insurrections, more or less bloody, broke out in all the German states. The princes, unable to resist these movements, hastened to yield to the popular demands. A national congress of representatives of the people (German parliament) was convoked by a provisional self-constituted assembly (*Vorparlament*), and met at Frankfort-on-the-Main, May 18, 1848. It formed a provisional national government, consisting of a vicar of the empire (*Reichsverweser*) and a ministry. Archduke John of Austria was elected vicar, June 29, but in spite of all his professions of zeal for national liberty and union, it soon became evident that his sole aim was the frustration of all energetic action on the part of the parliament. Distracted by the troubles in Holstein, which Denmark endeavored to wrest entirely from its connection with the German confederation, the parliament made but slow progress in the framing of a national constitution. When at last the bill of rights had been agreed upon (Dec. 1848), the counter-revolution had already been victorious in Austria and Prussia, and it became apparent that these great powers would not submit to a constitution framed by the popular congress. Then a strong party began to advocate the exclusion of Austria from the new empire. This party, whose principal leader was Gagern, prevailed in the parliament, and elected the king of Prussia German emperor, or rather emperor of "Little Germany," as it was called derisively by those who scouted the idea of a German empire not including Austria (March 20, 1849). The king of Prussia declined the proffered honor. Despairing of success, a number of members of parliament resigned their position, thus giving a majority to the democratic party, who proceeded to elect a provisional regency of the empire, consisting of Raveaux, Vogt, Schüller, H. Simon, and Becher. Reduced to less than one-third of its original number, the parliament adjourned to Stuttgart, May 30, 1849, and endeavored to raise a popular revolution in favor of the new national constitution. But only the people of Baden, a small part of Württemberg, and the Palatinate (Bavaria) followed the example of Saxony, which had already risen in revolution. The insurrection at Dresden was suppressed after a sanguinary battle by Prussian soldiery; and the revolution in Baden, although successful for a few weeks, was likewise crushed in a brief campaign by the Prussian army (June). The rump parliament at Stuttgart had, in the mean time, been forcibly dissolved by the gov-

ernment of Württemberg. Having thus got rid of all revolutionary support, the Prussian government attempted to obtain the mastership of Germany on its own account. Austria, almost prostrated at the time by the Hungarian war, would have been able to offer little or no resistance to such a movement if carried on energetically and rapidly; but the weak and imbecile Prussian government was no match for the bold and shrewd Prince Schwarzenberg, at that time the soul of the Austrian government. In April, 1850, Prussia convoked at Erfurt a new parliament of representatives of those petty states which were too powerless to resist its demands, and a sort of federal constitution was adopted by it, but never obtained any real existence. In order to cut short all further attempts of Prussia, Austria convoked the old diet, which had been formally dissolved in 1848. Prussia refusing to recognize the diet, a hostile conflict between Austria and Prussia seemed almost inevitable. The armies of both were marching to Hesse-Cassel, and a skirmish of the outposts had already taken place near Bronzell (Nov. 8, 1850), when suddenly the Prussian government lost courage and submitted to all the demands of Austria. The first fruits of the restoration of the diet were the intervention in Schleswig-Holstein in favor of Denmark, the abolition of the national bill of rights and of free constitutions in several of the smaller states, the sale by auction of the national navy which had been created by voluntary contributions of the people during the revolution, &c. While in these questions the influence of Austria prevailed, Prussia balanced its loss of political power by the enlargement of its commercial influence. Hanover became a member of the Zollverein (Sept. 7, 1851), and was soon followed by Oldenburg and Schaumburg-Lippe. The efforts of Austria to enter the Zollverein, in order to destroy the Prussian influence even there, were successfully resisted by Prussia, but a postal and telegraph union of all German states was accomplished. During the oriental war (1854-'56) the German confederation followed a vacillating policy, swaying to and fro between Austria and Prussia. On April 24, 1854, Austria and Prussia concluded a treaty of alliance, guaranteeing to each other their possessions against all enemies whatever. The diet joined in this treaty July 24, and added another clause, promising the assistance of all Germany to Austria if its army of occupation in the Danubian principalities should be attacked (Dec. 9). Preparation for war was resolved upon by the diet, Feb. 8, 1855. After that the position of Prussia toward Austria became more reserved, and Austria, despairing of an active assistance on the part of the confederation, was compelled to relinquish its intention to take part in the war against Russia. The peace of Paris was accepted by the diet, May 15, 1856. On Nov. 6, 1856, the diet adopted a resolution promising to assist Prussia in its attempts to reconquer Neufchâtel, but the proffered assistance

was not required. In 1857 the interference of the diet was requested against Denmark's attempts to merge the duchies of Holstein and Lauenburg completely into the Danish kingdom. After long hesitation and delay, a resolution was at last adopted in 1858, by which the Danish government was compelled to submit its project of a new political organization to the legislative assemblies of the duchies. A currency convention was concluded between all the German states, Jan. 24, 1858, and went into effect Jan. 1, 1859. When, in the beginning of 1859, difficulties arose between France and Austria on account of the state of Italy, a violent anti-Napoleonic feeling manifested itself in Germany. A large portion of the press was ready to maintain that the preservation of a German power in S. E. Europe, and the prevention of a combined Russo-French preponderance on the continent, were more essential to the eventual interests of liberty than the annexation of the Italian provinces of Austria to Sardinia. The Prussian government, though willing to defend Austria's German provinces, and even the Venetian kingdom, under certain restrictions, would not stir unless it should obtain the military leadership of all Germany, irrespective of all limitations contained in the act of confederation. After long and angry discussions the leadership was conceded to Prussia by the smaller states, though with a very bad grace, and resolutions originating with Hanover, to the effect that the federal army should be mobilized—thereby forcing Prussia to submit to the directions of the diet—were withdrawn in order to enable Prussia to assume a leading and controlling position. A circular despatch of the Russian government, covertly threatening Germany if it should interfere in the Italian war, had no other effect but the assumption by Prussia of a more defiant attitude toward France, and the issue of an order by the prince regent to mobilize two-thirds of the Prussian army (June 14, 1859). On June 25 the Prussian delegate in the diet moved that two federal army corps under the command of Bavaria be stationed on the upper Rhine, one Prussian corps on the Main, and that the 9th and 10th federal army corps be united with the Prussian army. This motion was followed by another (July 4), to the effect that the diet should appoint a commander-in-chief of the non-Prussian and non-Austrian army corps. Thus the German confederation appeared to be on the very point of waging war against France, under Prussian leadership, when all at once Austria, unwilling to sacrifice its preponderating influence in Germany to the doubtful project of preserving its Italian provinces, introduced in the diet (July 7) a resolution to mobilize the whole federal army, and to appoint the Prussian prince regent commander-in-chief, subject however to the control of the diet, or rather of Austria, the latter being always certain of a majority in the diet. This movement at once neutralized all advantages Prussia had obtained, and when the prelimina-

ries of peace were agreed upon by the emperors of France and Austria, July 11, the dissension and jealousy between Austria and Prussia, those great impediments of German unity, were more apparent than ever before. A passage in the Austrian emperor's proclamation of peace, in which he asserted that his natural allies had forsaken him, and that the neutral powers would have imposed upon him less favorable terms of peace than were offered to him by his adversary, gave rise to an acrimonious correspondence between the Austrian and Prussian governments. The latter succeeded in proving that the assertion of the emperor had no foundation in fact, and that he had been purposely misled by false representations of the French ruler at the interview of Villafranca. However, this singular discovery did not render the feeling of Austria any more friendly toward Prussia. A paper war was carried on by the presses of southern and northern Germany, and while the governments of those petty states who had been the most forward in their hostile demonstrations against France were eagerly courting the favor of Napoleon III., the most sinister threats against Prussia came from Vienna, Munich, and Karlsruhe. The opinion became prevalent that, Austria having been humbled by France, if a war for the conquest of the left bank of the Rhine should be waged by France against Prussia, the latter would not obtain any assistance either from Austria or the smaller German states. The hostilities of the two great sections of Germany manifested itself in sanguinary riots in the mixed Prussian and Austrian garrison of the federal capital (Aug. 6-8). Feeble movements were initiated by the liberal party to stem the progress of disunion, and to prompt the Prussian government to take the lead in reforming the federal constitution. But Prussia, disheartened and unwilling openly to oppose the influence of Austria, declined the destiny which the liberal party pressed upon it, and would promise nothing more than the promotion of liberal institutions by the power of its example. Austria, on the other hand, made some show of concessions to the popular wishes, in order to divide the current of the sympathies of the popular party in Germany. A committee was appointed by the emperor (Aug. 1859) to draw up a constitution upon the basis of provincial representation for the Austrian empire. At the same time another movement was initiated in Bavaria, the object of which was the creation of a separate confederation of the central German states, as a third great power within Germany. The same idea had been promoted by Bavaria in 1850, and then led to confusion and disunion.

GERMANY, LANGUAGE AND LITERATURE OF. The Teutonic (*Teutsche* or *Deutsche Sprache*), in the widest acceptation of the term, is one of the 6 families of the Indo-European stock of languages. It consists of two branches, viz.: the northern or Scandinavian (see DENMARK, SWEDEN, and ICELAND, LANGUAGES OF), and the

southern or German of the continent. The latter has 8 subdivisions, viz.: the eastern or Gothic, with its kindred idioms; the high German of 3 periods of time, old, middle, and new; and the low German, which also comprehends the Frisian, old Saxon, Anglo-Saxon, Dutch, and Flemish. In a still stricter sense, the 3 last mentioned languages are excluded from the German proper, which is now chiefly represented by the high German literary idiom. The terms language or tongue, and dialect or idiom, cannot in our restricted space be precisely distinguished from each other, owing to the vagueness of the limit that separates them; nor can we give a complete account of all ancient idioms of the Heruli, Gepidae, and other ancient portions of the German people. We shall treat of the boundaries of the principal dialects, of the chief characteristics and of the grammatical and lexicographical literature of the German language in succession; taking the modern high German as the basis of comparison.—The boundaries within which the German language, in all its dialects, is spoken, are as follows: the S. boundary of the Flemish tongue (see FLEMISH LANGUAGE); the W. boundary of Prussian Rhineland; a line through Luxemburg and Lorraine, crossing the Moselle above Thionville; the ridge of the Voeges as far as Thann; thence a line to Laupen in the canton of Bern, along Lake Biemne, touching the N. extremities of the lakes of Neuchâtel and Morat; through the canton Freyburg, along the Saane, to the Alps; S. along these through the Valais to Leuk on the Rhone; from Leuk S. E. a short distance into Piedmont, passing W. of Monte Rosa; thence following the ridge of the Alps N. E. over the St. Gothard pass to the junction of the cantons Glarus, St. Gall, and the Grisons; E. to the Albula, N. E. to the Engadine, and across the Inn into the Tyrol; thence S. E. to the Adige, south of Salure; considerably E. of Bozen, Brixen, and Brunecken; along the ridge of the Carnic Alps, separating Venice from Illyria, as far as Pontafel in Illyria; across the Gail valley toward Villach on the Drave; thence to the confluence of the Lavant with the Drave; E. through Styria over the Mur into Hungary. The boundary between the German and Magyar and Slavic regions is very ill defined; the greatest portion of the counties of Oedenburg, Wieselburg, one third of Eisenburg, some towns of Presburg, and many parts of other counties, being inhabited by Germans. Northward from Presburg the line follows the Danube and the March, thence by a line passing near Brünn and Znaim to Bohemia. The Cechs, to the amount of about $\frac{1}{3}$, occupy mostly the plains of Bohemia; while Germans hold the rest, being most numerous in the cities. Silesia is also divided between the German and Slavic elements. Prussian Silesia is mostly German. The German portions of Galicia contain about 170,000 inhabitants. The Slavi are found in Brandenburg within German territory on the Spree and Oder; also in Saxony, in Altenburg, &c. This

is owing to the ancient occupation of the eastern portion of Germany by Slavic tribes. The same is the case with Pomerania, both Mecklenburgs, and both Prussias, which were conquered by Germans from the Slavi, especially from Poles and the ancient Prutzi. Posen is divided into a Polish and a German portion. The German element has made and is continually making inroads upon the Slavic. Tilsit and Memel are German towns in Lettic territory. The nobility and the people of several cities of the Russian Baltic provinces also speak German. The shores of the Baltic from the Curische-Haff to the Eider (with the exception of 5,000 Kassubes in Pomerania) are the northern boundary of the German tongue. Two broad strips on the shores of Schleswig (the eastern beyond Flensborg, the western almost as far as Tondern), and a portion of the interior, comprising in all about $\frac{1}{3}$ of the duchy, are peopled by Germans. The shores of the North sea and the English channel as far as Gravelines complete the boundaries of the German language, taken in its widest signification. But outside of these limits there are detached portions of territory, as in Belgium, around the Splügen, near Vicenza, and in the diocese of Padua, where German is the language of the people. The whole number of Germans or Teutons in Europe amounts to about 51,000,000; of these there are 48,000,000 within the German confederation, and the rest in Holland, Belgium, Switzerland, France, Hungary, Transylvania, Schleswig, Galicia, Posen, and Italy. Many Germans are also found in all countries of the earth, especially in the United States of America.—The principal dialects of the German proper are as follows: I. Upper German, in two sections: 1. Southern German, south of a line from Strasbourg to the Bohemian forest; subdivided into: a. Alemannic, spoken on the upper Rhine, in Switzerland, where almost every canton has its own idiom, in Alsace, in the upper Black forest, with many varieties; the Sylvian, near Monte Rosa in Piedmont; the idioms in the Breisgau, Vorarlberg, &c. Specimens of words are: *Zit, Hús, khlug, Khranz, Milach, Liacht, sáje*, &c., for the modern high German *Zeit, Haus, klug, Krans, Milch, Licht, etc.* b. Swabian (*Schwäbisch*), less ancient, spoken in the greater part of Württemberg, between the Black forest and the river Lech, as far south as the lake of Constance; with varieties on the upper Danube, in the landgraviate of Baar, about Memmingen, on the Neckar, and about Ulm and Augsburg. Specimens: *Neabel, Weag, Schweschter, Bruschtkaschte, ligge, oba, W., Wuscht*, &c., for *Nebel, Weg, Schwester, Brust-Kasten, liegen, oben, Wirth, Wurst.* c. Bavarian (*Bairisch*), spoken chiefly in Bavaria, where are heard the old idiom and the idioms of Munich, Hohenschwangau, Hochland, and Saltzburg; in the Tyrol, including the idioms of the Zillerthal, Innthal, and Lientz; in the Italian *communi* in Austria, where, beside the Gottschee idiom, there are 6 varieties in Styria, 4 in Moravia, 4 in Lower Austria, others in Upper Austria, in

Carinthia, in Carniola, Bohemia, upper Silesia, the Zips and other parts of Hungary, and in Transylvania. Specimens: *lobm, geschlogen, gwe'n, haß, heisse, &c.*; Austrian, *hämlich*; Zipsish, *Ich bin noch bu mai föts es, &c.*; for *leben, geschlagen, gewesen, heiss, heisser, heimlich, Ich weiss nicht wo mein Vater ist*. The remnant of the Gothic dual *iggis* (to you two, old high German *inck*, old Saxon *inc*, old Norse *ycker*) occurs in Austria in 3 cases (nominative *enk, es*, or *tes*; genitive *enker*; accusative *enk, enkes*).

2. Middle German, south of a line drawn through Aix la Chapelle, Cassel, Nordhausen, Wittenberg, Orosen, and Meseritz; with very many varieties. *a.* In its western region is the Franconian dialect, which extends to the Rennsteig of the Thuringian forest, and from the Odenwald to the Fichtelgebirge and Bohemian forest, and has two sections, viz., one in the west, in the Odenwald and the Spessart, on the lower Main, in the Palatinat, with other varieties about Treves, Cologne, in Hesse, &c.; and the other section in the east, with varieties about Nuremberg, on the upper Saale, upper Main, in the Voigtland, in the N. W. of Bohemia, &c. Specimens: *Hersch, Fersch, Dorsch, wärsch, W. lib, gout (E. lib, gut), &c.*, for *Hirsch* (stag), *Fürst, Durst, wäre es, lieb, gut*. *b.* In the eastern region, the upper Saxon has 3 subdivisions, viz.: the Thuringian, south of the forest ridge as far as the offshoots of the Hartz, and from the middle Werra to the Saale, with several varieties; the Misnian (*Meissner*), which is the softest of all, and the basis of the modern literary high German (*Neuhochdeutsch*), with its collaterals in the Osterland, Voigtland, Erzgebirge, Lusatia, &c.; and the Silesian, spoken also with variations in Moravia, in the Sudetic mountains, in Poland, &c. There are also several idioms in the Prussian and Russian provinces running along the Baltic shore east of Brandenburg. *II.* Lower German, in the belt north of the preceding, mostly in the country districts; high German being spoken in the cities. It has 3 groups: 1. Low Saxon (*Plattdeutsch*), with varieties in Hamburg, Holstein, Schleswig, Hanover, the Longobardo-Kymric, &c. 2. Eastern low Saxon, with idioms in Mecklenburg, on Rügen, in Pomerania, East Prussia, and Brandenburg. Specimen of the last: *Yoben Sie mich ene yut gebratene Yans, for Geben Sie mir eine gut gebratene Gans*. 3. Westphalian, west of the Weser, almost to the Rhine, with sub-dialects in Bremen, Osnabrück, Münster, Paderborn, &c. Specimens: *Bauk, Faut, Deif, Mensch, &c.*, for *Buch, Fuss, Dieb, Mensch*. The Saxon Westphalian is spoken in the Polish provinces of Prussia beyond Thorn. A more important mixture is that of the dialect of the lower Rhine with upper German sounds, as between Jülich, Cologne, Elberfeld, and Wesel, &c.—We know but few names of persons and places in Teutonic before the 4th century of our era; for instance, Segimerus, Inguiomerus, Ac-tumerus, of the Cherusci, mentioned by Tacitus, and Chrodomarius, Vadomarius, Hariobandus,

&c., occurring among the Alemanni, much later. Now, *mors* in Gothic, and *mari, märe* in old high German, signify celebrated, and *hazis* (*hari*), now *Heer*, signifies army; hence those names refer to the celebrity of their bearers on account of victories and other great deeds. Gothic is the first dialect known through the version of the Bible by Ulfilas (about 380). A few proper nouns and glosses remain to us of the Burgundian. Old high German is known by monuments of the 7th century, when it was split into 8 groups, viz.: upper German among the Alemanni, Bavarians, and Longobards; low German among the Frisians, Saxons, and Westphalians; and a middle group in Hesse, Thuringia, and Franconia. The eastern part of Germany was at that time in the possession of Slavic tribes. The Franconian dialect prevailed during Charlemagne's reign, and for some time after; the Longobardic early ceased to be spoken. The Frisians had already rendered their tongue literary, and Anglo-Saxon had been introduced into England about the middle of the 5th century. In consequence of their independence of the German empire, the Flemings and Hollanders developed their dialects into literary languages. The literary monuments of all the dialects belong more properly to the history of German literature; we may only mention that the middle high German became literary in the 12th century; that its poetry gave it predominance as far as Austria, and that it was surpassed during the 18th century by the Swabian, which obtained a still wider field. The other dialects strove to rival these two; but all the writings of the 14th and 15th centuries show the influence of the Swabian. The low German *Sachsenspiegel* and other law books were translated into upper Saxon, which at last became the dominant language, in consequence of the translation of the Bible by Martin Luther, and other circumstances which favored the development of the Misnian dialect into the modern literary high German. This and other dialects were much corrupted by admixtures from foreign languages, especially during the 80 years' war, which deluged Germany with hosts of strangers. Neither the influence of Opitz and his school, nor the efforts of several societies for the purification of the language, could withstand these inroads upon it. But Thomasius, toward the close of the 17th century, raised the fortunes of the language by making it the medium of scientific pursuits. Gottsched (1700–1786) reduced it to fixed rules, and the Swiss school, Haller, Hagedorn, Klopstock, &c., continued to perfect it. Lessing, J. H. Voss, Wieland, Herder, Schiller, Goethe, and others in poetry, Winckelmann, Kant, and Oken, in criticism and philosophy, brought it to its present eminence. Klopstock and others asserted that high German was a primitive language, and *sui generis*; but Wachler and others have shown its connection with the so called classic and other tongues. C. Frank, Dorn, Von Hammer, &c., proved it to be cognate with

Sanskrit, Greek, Persian, &c. Adelung, Morich, &c., went so far as to say that these languages were but developments of the German, which the Teutons had left in the course of their migrations. Bopp, Eichhoff, &c., demonstrated the close affinity with the above-mentioned languages, and with the Zend, Huzvareh, Latin, Greek, and Lithuanian, both as regards the words and their grammatical forms. Prichard, Dieffenbach, &c., demonstrated its relationship with Celtic. Confining ourselves to its comparison with Latin, by a union with which it produced the modern Romanic languages (see *FRANCOIS, ROMANESQUE* or) and the English, we find that the material of which both consists is essentially identical, and that the grammatical forms of the German are but relics of the Latin pronominal suffixes. Thus: *oc-ulus—Aug-e; aur-is—Ohr; nas-us—Nase-e; gen-u—Kinn* (but misplaced); *cap-ut—Kop-f (Haupt, Kap-pe); crin-is* and *corn-u—Harr* and *Horn; cut-is—Haut; unguis, umb-il-icus—Nag-el, Nab-el* (transposing *n* and *g*, and altering *m* to *n*); *arm-us—Arm; pes—Fuss; man-us* and *compre-hend-ere—nehmen* (transposing *m* and *n*) and *Hand; pater, mater, frater, socer—Vater, Mutter, Bruder, Schwager; ac* and *jug-um (jug-um)—Och-s* and *Joch* (both words from the connecting *c* with *i* prefixed in the latter); *cib-us* and *coo-a—kau-en* and *Kuh* (Eng. *chew, cud—chewed, cow*); *su-s (sui-us)—Schwein; hœd-us—Geis* (Eng. *goat, hid*); *vol-uer-is (volo acris)—Vogel* (Eng. *fowl, flock*); *pisc-is—Fisch; aqu-a—Au* and *Gau; terra* and *arid-us, tor-reo—Erd-e* and *dürr, tro-cknen; gra-men* and *gra-ndia, cre-sco, gruo—Gra-s, gro-s, Kraut; sol-ium—Blat-t; vent-us—Wind; sol—Son-ne; stel-la* and *astr-um—Ster-n; di-ce—Ta-g; nox, noct-is—Nacht; hest-er-us—gestern; eg-o, tu, is (id)—ich, du, es; tu-us, du-o, tri-a, qu-a(t)uor, qu-in(q)u-e, sex, sept(im), oct-o, nov-em (non-us), de(c)em, cent-um—ein, zwei (zwei), drei, vier, fünf, sechs, sieben, acht, neun, zehn, hund-ert; sta-re, co-se, ed-ere (a-um), sed-ere and sit-us—sto-hen, se-en, es-sen, sit-en, sets-en; and innumerable other common sound-tokens of indispensable and primitive objects and ideas. The following are a few specimens of compounds: *o-blig(a)t-io—Pflicht; in-vent-um—find-en; calen-a (con-tinens)—Kette; con-duc(t)-ere—Neis* (Eng. *net, k-nit, k-not*); *sparg-ere (dis-perg-ere)—Sprach-e (sp[r]eech, a spreading out of what we think); and innumerable other groups of concrete roots. (See the single letters from D to Z.)—On the whole, the Teutonic dialects (or languages) are characterized by 5 peculiarities: 1. The weakening of pure into impure sounds, thus of *a* into *i* or *e*, as in Anglo-Saxon and English, where the former sound was very often changed into the latter. 2. The breaking of *i, u* before *r, h*; thus, Goth *airpan*, old high German *werfan*, old Norse *verpa*, Anglo-Saxon *veorfan* (to warp, to throw, wharf). This corresponds with the Sanscrit *Guna*. 3. Metaphony (*Umlaut*), on account of succeeding formative syllables, especially in Anglo-Saxon, Norse, and high Ger-**

man; thus, *hart, härter; Ort, Oarter; wurde, würde*. This is confined to the softening of *a, o, and u*. 4. Apophony (*Ab laut*), not on account of accessory syllables, and affecting *e, ei, i, ie*, and also *a*; thus, *galten, galt, gegolten; sprechen, sprich, sprach; reiten, ritt; sitz-en, sass, gesessen; schieben, schob; fallen, fiel, &c.* This occurs in all the dialects. 5. The shifting (*Lautverschiebung*) of consonants from one to another degree of intensity within their organic homogeneity. Jacob Grimm's scheme showing the correspondences is as follows:

Greek	K	Γ	X	Π	Β	Φ	Τ	Δ	Ζ
Gothic, Saxon, Frisian	H	K	G	F	P	B	T	H	T
Old high German	G	O	H	K	B	V	F	P	D

The vowels *a, e, i, o, and u*, and the consonants *b, d, f, g, h, k, m, n, p, r, s, t, v, and z*, are common to all the dialects; beside which *ä, ö, ü* (or *ae, oe, ue*) are used in modern high German; and *c* is used instead of *k* in Anglo-Saxon, and instead of both *k* and *s* in other dialects. The letters *j, k, g, y, and x* are wanting in Anglo-Saxon, where *co* occurs instead of *q*. The Gothic and Northern *þ* represents the Greek *θ*, or the English *th* as in *thick*, and the Anglo-Saxon *ð* stands for our *th* as in *this*; the *y* begins to be abandoned in high German, unless it occurs in Greek and other foreign words; the high German *ch* sounds like the Greek *χ* or Spanish *jota*.—The old dialects had more flexional affixes than the present. (See *GOOTHIC LANGUAGE*.) They also show a trace of the dual number, as mentioned above. The interrogative and relative pronouns were written with *hō* instead of the English *wh*; for instance, in Gothic *hwarjō*, which one of several; *hwarthar*, whether. The Gothic and the Scandinavian languages have a proper passive form of the verb; there are also faint traces of a middle voice in the Gothic and of a reflexive form in old Norse. The present and past (vulgarly called the imperfect) are the only simple Teutonic tenses. The present was anciently used instead of the future. Excepting in the Scandinavian languages, the infinitive ends in *n*. The ancient personal endings of verbs were: 1st person, *a, or e*; 2d, *s*; 3d, *th, t*; plural, 1st, *m*; 2d, *th, t*; 3d, *nd*. Conjugation was of two kinds: 1, strong (wrongly called complex and irregular), when the stem vowel undergoes apophony in the past tense and in the passive participle; thus:

Gothic	giba, gaf, gebun, gibana.
Anglo-Saxon	gife, gearf, gearfon, gifen.
Old Saxon	giba, gearf, gearfon, gifen.
Old Norse	gaf, gaf, gafun, gafna.
Swedish	giver, gaf, gifva, gifven.
Danish	give, gaa, gaa, givne.
English	give, gave, gave, given.
Old high German	giba, gab, gabun, gaban.
Middle high German	giba, gap, gabun, gaben.
New high German	gabe, gab, gaben, gegeben.
Latin	cap-io, cep-i, cep-erunt, cap(t)um.*

2. Weak (improperly called regular), without apophony, indicating the corresponding forms by the insertion of *d, th, t* between the stem

* The signification of this word is inverted in the above derivatives; but in English both the original and inverted sense are used, in the words *keep* and *give*, in analogy to the Latin *calidus*, warm, and *gelidus*, cold. These examples are from the roots *c-p* and *o-l*.

and the ending; thus: Goth. *libaida*, *libaiþs*; Eng. *lived*; new high Germ. *lebte*, *ge-lebt*. (See GOTHIC LANGUAGE.)—We shall restrict our remarks henceforth to the new high German language. The 5 vowels *a*, *e*, *i* (*y*), *o*, and *u* sound as in Spanish; *a* is like the English *ai* in *mail*; *o* is somewhat duller than the French *ou* in *fou*; *u* is also duller than the French *u* in *sur*. *Ö* before *e* and *i* (*y*), and *z* always, stand for *ts*, as in English *pets*; *ck* for *kk*, as in English *peck*, *suck*; *g* is always hard, as in *get*, *give*, and is sometimes almost like *ch*, as in *ewig*, *weg*, or even like *y*, but only dialectically; *h* before a vowel has the same sound as in our *has*, *hen*; *ch* is harsher than *h*, and like the Greek *χ*, or the Spanish *jota*; *r* is always whirling. *S* has a threefold sound: 1, like the Latin *s*, in the combination *st*, at the end of a syllable, as *fest*, *Fürst*, and in forms derived therefrom, *festest*, *Fürsten*, &c., at the end of words, as in *das*, *gutes*, &c., and when double, as in *nass*, *Wasser*, &c.; 2, like the English *s*, at the beginning of words, before vowels, and between vowels, as in *Sonne*, *dieser*, &c.; 3, like the English *sh* in *shell*, at the beginning of words before some consonants, as *Scandal* (Latin), *spät*, *still*, &c., where Low Germans and some others pronounce it like the English *s*. *Sch* is like the English *sh* in *shall*. *ss* stands for *ss* after long vowels or at the end of words, and is thus written in derivative forms, as *Mass* and *messen*. *Eu* has a very peculiar sound, approaching the English *oi*, and *äu* is somewhat heavier. *E*, the weakest sound, is most frequently employed, to wit: 1, for filling up the transition between consonants, thus, *er liebet* for *liebt* (the latter form is now more common); hence it is often elided, as *nah'n* for *nahen*, as in English *pow'r* for *power*, *heav'n* for *heaven*; 2, for lengthening *i* when that letter precedes it, as in *wieder*, again, distinguishing it from *wider*, against, counter; 3, as a mark of the plural, as *Steine*, stones, from *Stein*. *H*, the weakest consonant, is also used for lengthening a preceding vowel, as in *sehr*, *wohl*, &c. Beside *a*, 3 dentals and 3 liquids serve for all grammatical inflections. They are *d*, *s*, *t*, and *m*, *n*, *r*; *s*, *m*, *n*, *r* are employed with nouns, *d*, *s*, *t*, *n* with verbs. The following is a synopsis of all grammatical endings attached to words: nominative (of the definite article) *der*, *die*, *das*, plural *die* for all genders; genit. *des*, *der*, *des*, plur. *der*; dat. *dem*, *der*, *dem*, plur. *den*; accus. *den*, *die*, *das*, plur. *die*. These are the endings of all adjectives, nouns, and adjective pronouns. Comparative *dicker*, superl. *dickeſt*; receiving the preceding endings when declined. Endings of substantive nouns: singular genit. *es* or *s*, as *Dorf-es*, or like the nominative; dat. *e*, or like the nominative; plur. *e*, dat. *en*—new declension everywhere *en* or *n* (*des Falken*, &c.). Some substantives take *r* after *s* in the plural, and undergo apophony, as in *Bad*, *Bäder*, *Volk*, *Völker*, *Tuch*, *Tücher*. The verbal endings are as follows: 1. Strong verbs (commonly called old conjugation): indicative present, *e*, *est* or *st*, *et* or *t*; plural, *en* or *n*, *et* or *t*, *en* or *n*; past, 1st and 3d persons have

no ending, 2d *est*, or *st*; plural, *en*, *et*, *en*; imperative singular, 1st person wanting, 2d and 3d *e*; plural, *en*, *et* or *t*, *en*; participle past, prefix *ge*, suffix *en*. 2. Weak verbs (improperly called regular, really inorganic conjugation) have the same terminations as the preceding, except in the past tense, where *et* or *t* is inserted between the stem and the ending; participle past, prefix *ge*, suffix *et* or *t*. In both the ending of the participle present is *end*, infinitive *en*. The subjunctive of both has the endings always preceded by *e*, and the past of the strong verbs undergoes metaphony, as *ich gab*, I gave; *ich gäbe*, I might give. The strong verbs, whose conjugation is wrongly called irregular, exhibit the phonetic vicissitudes of words, and are therefore to be regarded as organic and containing the rules of the language; while the so called regular verbs are weak, undergo no change, and only admit of mechanical additions.—Although the essential bulk of the German language is of the same origin as that of the Latin, we consider those words to be Teutonic which have undergone such disguises as to appear at first sight to be *sui generis*. Such are especially those written with *pf*, *z*, *ch*, *w*, *f*, or *v*; for instance: *Pfau*, *Zehn*, *zehn* and *-zig*, *Becher*, *Wolle*, *flach*, *Vater*, &c.; compare *pan-o*, *dig-itus* (*pedis*, Eng. *toe*), *dec-em* (thus *swan-zig*, *duo-dec-em*, 2x10), *pocal-e*, *vell-us*, *plan-us* (Gr. *πλάν-ος*, broad), *pater*. All words of Teutonic physiognomy have the accent on the radical syllable; those taken from or resembling French, generally on the last effective syllable; and those from other languages on that syllable which to the German ear seems to be the radical; thus: *Empfind-lich-keit*, sensibility; *unseuerlich*, untrustworthy, &c.; but *Regiment*, *Solidarität*, *Kapitan*, &c.; *Aristoteles*, *So'krates*, &c. The German language has in a very high degree 8 qualities which render it both very plastic in its material and very flexible in its adaptability to all forms and categories of thought. Those qualities are: 1, intuitiveness of expression, owing to the organic etyma of the Indo-European family of languages, which are clearest in the Latin (see LANGUAGE); 2, facility of composition of simple words into double or manifold agglomerates, requiring lengthy paraphrases in other languages; 3, power of polysyllabic derivatives from radical words. These latter qualities do not impair the first. We conclude with some examples of these characteristics, and with a comparison of a few Anglo-Saxon phrases with Latin, English, and German. *Unersänglichkeit*, uncaptionness, unprejudicialness, composed of *un*, not; *er*, for (as in *forget*; Lat. *per*); *säng-en* (to catch, seize; Lat. *fig-ere*; whence Eng. *fang*, *finger*); *lich* (Eng. *ly*, from *leicht*, light, easy; Lat. *lev-is*); *keit* (or *heit*, Eng. *head*, *hood*, as in *Godhead*, *manhood*; contracted from Lat. *qual-it-as*, as *quis*, *quid* are lengthened into *qualit-as*); hence, quality of not being lightly fanged (fixed, fingered).

Willkommen, *schöner* *Jüngling!*
Wel-come, beautiful (shining) youth!

De Wonne der Natur!
Thou joy (win, gain) (of) the nature!
Mit deinem Blumenkörbchen,
With thy (two) flower-basketlet (Lat. *flor* and *corbicula*),
Willkommen auf der Flur.
Welcome on (upon, b'rep) the (dative) field (flat, plan).

The following lines exhibit the German in comparison with the Latin, Anglo-Saxon, and English:

Ego sum major	quam	ista media
I am wares	thonne	this middle
I am greater (grandior)	than	this middle
Ich bin größer	als (altus, else)	diese Mittel-
ragio, minor	(plan) (Hof verm-ke,	
guard, lance	thonne land-wurm,	
region, less	than	land worm,
Gepard, kleiner (in-clin-)	als	Land-Wurm,
leior — luna (men-eurone),	celorior	
lighter thonne moon,	swifter	
leichter als Mond,	schweller (schweifender)	
quon col; maria (salia) mlti	sunt omnia.	
thonne wares; seas	ma sind alla	
— sea; seas	(to) me are all (belonging).	
— Sonne; Seen	mir sind alle (gehörig).	

—Among the most eminent of the founders of German philology are Benecke, J. and W. Grimm, and Lachmann. See J. Grimm, *Deutsche Grammatik*, comprising also the Scandinavian branch (Göttingen, 1819-'87); Hoffmann von Fallersleben, *Deutsche Philologie im Grundriss* (Berlin, 1836), with a bibliography of dialects; Pischon, *Denkmäler der deutschen Sprache* (6 vols. Berlin, 1838-'51); Wackernagel, *Deutsches Lesebuch* (3 vols., Basel, 1839-'43); J. Grimm, *Geschichte der deutschen Sprache* (Leipzig, 1848). For old high German see Graff and Massmann, *Althochdeutscher Sprachschatz* (Berlin, 1833-'44); for middle high German, Benecke, W. Müller, and Zarneke, *lexicon* (Leipzig, 1854). For grammars of new high German, see Ickesamer (1580); Albertus (Augsburg, 1573); Öttinger, *Unterricht der hochdeutschen Sprache* (Strasbourg, 1574); Olajus, *Grammatica Germanica Lingua* (Wittenberg, 1578); Martin Opitz, on German prosody (Brieg, 1624); Schottel, *Deutsche Sprachkunst* (Brunswick, 1641); Morhof, *Unterricht von der deutschen Sprache und Poesie* (Kiel, 1682); Bödiker, *Grundriss der deutschen Sprache* (Cologne, 1690); Brann (Munich, 1765); Heynatz (Berlin, 1770); Basedow (Copenhagen, 1759-'72); Bodmer (Leipzig, 1775); Fulda, *Grundregeln der deutschen Sprache* (Stuttgart, 1778); Adelung (Berlin, 1781-'2); Heinsius (Berlin, 1798); J. Ch. A. Heyse (Hanover, 1814); K. F. Becker (Frankfort, 1829). For dictionaries, see Frisch, *Teutsch-lateinisches Wörterbuch* (Berlin, 1741); Adelung (Leipzig, 1774-'86); Moritz, *Grammatisches Wörterbuch der deutschen Sprache* (Berlin, 1793); Campe, *Verruche deutscher Sprach-Bereicherung* (Brunswick, 1791-'4), and *Wörterbuch zur Aufklärung und Verdeutschung der unserer Sprache aufgedrungenen fremden Ausdrücke* (1801; modified by Brandt, 1807-'18); Heyse, *Allgemeines Wörterbuch zur Verdeutschung*, &c. (Oldenburg, 1804); Heinsius, *Volks-thümliches Wörterbuch* (Hanover, 1818-'82); Adler, *German and English* (New York, 1848); K. W. L. Heyse (Magdeburg, 1838-'49); J. and

W. Grimm, a gigantic work, not yet completed (Leipzig, 2 vols., 1852-'9). On synonymes, see Gottsched, *Beobachtungen über den Gebrauch und Missbrauch vieler deutscher Wörter* (Leipzig, 1758); Heynatz (Berlin, 1795); Eberhard (Halle, 1802); Maass, Wiegand, Ch. F. Meyer, &c. —GERMAN LITERATURE received its first impulse from the fondness of the early Germans for celebrating in song the fabulous and heroic associations of their traditions and history. The legends immediately connected with Gothic, Frankish, and Burgundian warriors of the period of national migration have for the most part some historical foundation, and many of them were eventually embodied in the lay of the *Nibelungen*, which is the most celebrated product of German mediæval poetry. The spirit of the *Nibelungen* is, according to Goethe, essentially pagan and mythological. Another sphere of literary activity was opened on the introduction of Christianity, manifesting itself as early as the 4th century in the translation of almost the whole of the Bible by Bishop Ulfilas, which is cherished by the Germans as the earliest monument of their ecclesiastical literature, although it was composed in the Gothic language. The British missionaries established cloisters and brotherhoods in Germany between the 6th and 8th centuries, and laid the foundation for that system of instruction which in the 8th and 9th centuries was perfected by Charlemagne. Metrical translations of the Gospels appeared in the 9th century in the old high and low German dialects, the former (*Krist*, new ed., Berlin, 1831) in rhymes, and the latter (*Heliand*, first published in Munich, 1830-'40) preserving the ancient alliterations. A translation of the Psalms by Notker, which dates from about the same period, is regarded as one of the best specimens of old high German literature. The *Ludwigslied*, a psalm in honor of the victory of the Frankish king Louis III. over the Normans in 883, which Herder extols as one of the best specimens of early German poetry, was composed in the old high German dialect by a Frankish churchman. The preservation of the song of Hildebrand, which is associated with the legends of Theodoric and Attila, is also due to churchmen, who transmitted it partly in the old high German and partly in the low German dialect. Several Latin poems were also based upon Hunnish and Burgundian legends, but with these exceptions the priesthood were generally opposed to the national poetry on account of its pagan associations. Many eminent Latin chroniclers and poets abounded in this and the following period; also a Latin poetess, Roswitha, or Helena von Rossow, who wrote Latin religious plays. The learning which flourished under the Saxon emperors was superior to that of the times of Charlemagne. The study of mathematics was next in importance to that of theology and Latin. The Greek language, although but little cultivated, was not unknown. From the 10th to the 13th century Germany probably possessed a higher mental cultiva-

tion than any other country in Europe, but it was on the whole of a Latin and ecclesiastical cast, and the people had no share in it. In the course of the 12th century appeared a hymn in praise of Hanno, archbishop of Cologne, which Herder calls a truly Pindaric song. Among the last poems which appeared in this era from the pen of churchmen were the *Rolandlied* and the *Alexanderlied*.—In the 12th and 13th centuries poetry passed from the monasteries and ecclesiastical schools to the palaces of princes and the castles of nobles. Most of the poets who then came forward were nobles by birth, some of them princes. Heinrich von Veldeke was the first to introduce into his heroic poem *Eneit*, which he is said to have composed after a French version of Virgil, the spirit of devotion to woman, or *Minne* (an old German word for love, whence the name *Minnesänger*). Veldeke is regarded as the originator of the heroic minstrel song, although he is far surpassed in genius, elevation of thought, and depth of feeling by Wolfram von Eschenbach. The other masters of the heroic muse were Gottfried of Strasbourg, Hartmann von der Aue, and Konrad of Würzburg. Their longer heroic poems treat chiefly of the exploits of Charlemagne and of the story of Arthur and the round table. At the same time they composed many songs. Love was their principal theme, but from a sense of delicacy the name of the lady who was the special object of adoration was never mentioned. Respect for womanhood, which was reckoned among the virtues of the ancient Germans even in the days of the deepest barbarism, contributed to make the German love songs more reverential than those of the French troubadours. A species of song peculiar to the bards was called watch songs, consisting in a dialogue between a lover and the sentinel who guards his mistress. Walther von der Vogelweide was the most gifted of these lyrical poets. Next to him rank Heinrich von Ofterdingen, Reimar der Alte, Heinrich von Morungen, Gottfried von Neifen, and the Austrian bards Nithard and Tanhauser. Several hundred of these poets were engaged in wandering from palace to palace and from castle to castle. The minstrels constituted what is called the Swabian school of poetry; the songs were mostly in the Swabian dialect. The accession of the Swabian emperors of the house of Hohenstaufen to the throne of Germany was the signal for the rise of the bardic art (1138). Its golden age was shortly before the fall of that dynasty (1254). The crowning event of the minstrel era was the appearance of the lay of the *Nibelungen*. It was followed at a subsequent period by the "Book of Heroes" (*Heldenbuch*), consisting of a collection of fragmentary pieces treating of the same legends as the *Nibelungen*, but mixed up with traditions of the crusades.—Didactic poetry began to be cultivated with some success in the 13th century. The dawn of historical works is heralded by several local chronicles; that of writings on natural history in the so called *Meinauer Naturlehre*;

of popular religious literature in the sermons of David of Augsburg and Berthold of Winterthur; and of works on jurisprudence in compilations of Saxon and Swabian laws (*Sachsen-Spiegel* and *Schwabenspiegel*). Ulrich von Lichtenstein deploras, in 1275, in his famous poem on *Frauentdienst* (devotion to woman), the decline of chivalry, but his attempt to revive its spirit was hopeless. Poetry now passed from the abodes of princes and knights to the homes of burghers and the workshops of artisans; and instead of *Minnesänger* we hear of *Meister-Sänger*, as the plebeian songsters were called. The 14th century, the greater part of which was so rich in poetical productions, was one of the most unfruitful for the cause of learning. Leibnitz says that the 10th century in Germany was a golden age in that respect compared with the 18th.—In the 14th century Germany possessed several mystic theologians, followers of Meister Eckart, the principal of whom was Johann Tauler (1294–1361), whose sermons and writings contributed to pave the way for the reformation. An important event of this century, in its general influence upon the future development of German literature, was the establishment of the university of Prague in 1348, soon afterward followed by universities in almost all parts of Germany. The last echoes of the period of chivalric poetry were two allegorical romances, *Teuerdank* in verse, and *Weiskünig* in prose (first published at the beginning of the 16th century), of which the emperor Maximilian is the hero and probably the author, although Melchior Pfinszinger is supposed to have composed the former romance at the emperor's request. The only good poetry of the 14th and 15th centuries were the spirited songs of Halbsuter and Veit Weber, celebrating the victories of Switzerland over Austria and Burgundy.—The progress of classical culture was stimulated at the opening of the 15th century by the foundation of the college of Deventer by Gerhard Groot (1400), and the subsequent establishment of many schools in imitation of it in different parts of Germany and the Low Countries. Hegius, Langius, Dringeburg, Reuchlin, Agricola, and other eminent men, were among the scholars. Purbach was the first restorer of mathematical science, and his pupil Regiomontanus (Johann Müller) was the greatest mathematician of the 15th century; while Gutenberg was one of its heroes. His invention of the art of printing produced a steadily increasing literary activity, and the books printed in Germany between 1470 and 1500 amounted to several thousand editions.—The 16th century opens with the foundation of the university of Wittenberg (1502), and inaugurates along with the reformation a new era in literature by Luther's translation of the Bible, which he rendered into German so harmonious and beautiful that it is still considered even at the present day as a model of elegant expression. The high German, as used by Luther, is so pure, that all the antiquated and anomalous dialects which had

until then alternately predominated in German composition were from that time more or less banished from the language, and the idiom of the Bible, which is now known as the high German (*Hochdeutsch*), has since become the sole medium of cultivated conversation and of German literature. Hymns and psalms were now brought to perfection. That famous religious lyric, *Eine feste Burg ist unser Gott*, and others of Luther's finest hymns, have become classical, and have found hosts of imitators, the most distinguished of whom were Decius and Speratus, and, in the 17th century, Paul Gerhard. Michael Weiss translated the hymns of Huss into German. The writings of Luther, Zwingli, and Johann Arnd, Bugenhagen, Bullinger, a theological work by Sebastian Frank, one on German theology by the Roman Catholic bishop Berthold, and a remarkable anonymous treatise, *Das Büchlein von der Theologie*, edited by Luther himself, constitute, beside the works by Melancthon, Ulrich von Hutten, and other reformers and scholars, the principal theological literature immediately connected with the reformation. In historical works, the influence of the reformation manifested itself in the superior style and greater comprehensiveness of the universal histories of Sebastian Frank and Sebastian Münster; also in chronicles of Switzerland by Tschudi, and of Bavaria by Aventinus. Frank also published a collection of German proverbs; in which branch of literature, however, he was preceded and excelled by Johann Agricola's *Auslegung deutscher Sprüchwörter*. Albrecht Dürer's writings unfolded original views of the fine arts in their connection with mathematical science. The principal events in prose belles-lettres literature were the translations into German of Latin tales, in which Boccaccio, Pogio, and other Italian novelists and poets, were for the first time introduced to German readers. Translations of Tasso and Ariosto also appeared. Many of the ancient chivalric stories, which had been published in prose in the 15th century, were republished in the 16th; collections of them were made and called *Volksbücher* (books for the people), of which the "Book of Love" (*Buch der Liebe*) became the most popular. The period before and after the reformation was especially fruitful in satirical and allegorical works. One of the most remarkable of the former kind was the *Narrenschiff* ("Ship of Fools"), by Sebastian Brant of Strasburg (new ed. by Zarncke, Strasburg, 1854), a metrical satire on the follies of the century, which, in the opinion of Hallam, may possibly have suggested to Erasmus his *Encomium Moria*. Thomas Murner imitated this in his *Narren-Beschörung* ("Conjuration of Fools"), and published one of his bitterest satires on Luther under the title, *Von dem grossen Lutherischen Narren* ("Of the Great Lutheran Fool"). The fable of *Reinolds Fuchs* (afterward immortalized by Goethe's poem), the origin of which is identified by many authorities with the ancient epic or didactic poem of the *Thiersage*, and

which in different periods had appeared in a variety of forms, was revived in a low German edition (translated from the Dutch) in the latter part of the 15th century, and was looked upon in the 16th as a satire on the government and state of society of Germany. It was followed by a great number of poems of the same kind, of which one whose heroes are fleas (*Flohate*) is the most witty. Among the purely didactic fabulists were Alberus and Waldia, both also eminent as composers of hymns. Among the more comic of the *Volksbücher* was the story of *Till Eulenspiegel*, relating the freaks, pranks, drolleries, fortunes and misfortunes of a wandering mechanic (new ed. by Leppenberg, 1854). The most able satirical and didactic poet of the 16th century was Johann Fischart (died 1591), the author of more than 50 works, including the above-mentioned fable on fleas (*Flohate*) and a romantic poem (*Das glückhafte Schiff*) which was regarded as a model for romancers. He has been called the German Rabelais. The story of Faust, and the autobiography of Götz von Berlichingen, afterward celebrated by Goethe, were also among the popular works of this century. The *Volkslieder* or popular songs of this period were much admired by Herder, who was the first to collect them. The *Meistersänger*, upon whom the mantle of the minstrels had fallen since the 14th century, had established metrical schools in various German towns, in the same spirit in which they would have founded guilds of trade. Their highest ideal of poetry was conformity to the rules of versification which were adopted by their school committees. In the 16th century their corporation derived great prestige from the genius of Hans Sachs, the poet and cobbler of Nuremberg (then the headquarters of the *Meistersänger*), whom Herder calls the *Meister of Meistersänger*, and who excelled more than any poet before him in all styles of composition, from the most tragical touch of feeling to the most comic turn of thought. His song dedicated to Luther (*Wittenbergische Nachtigall*) was especially fine. Frauenlob and Michael Behaim were also poets, and Rosenblüt and Folz playwrights of some note, the former of whom was also one of the best tale writers of his time. Among the contributors to the drama who succeeded Hans Sachs, he was excelled in skilful arrangement of plots by Jakob Ayser (died 1606), and in grace and refinement of composition by Andreas Gryphius (1616-'64).—During the excitement occasioned by the reformation almost all branches of composition were cultivated, but in learned and scientific literature the 16th century was most prolific. Beside Melancthon, whose influence secured the preponderance of the Aristotelian philosophy in the Protestant schools of Germany for over a century, there were Luther, Camerarius (classics and philology), Cornelius Agrippa, Theophrastus Paracelsus (mystical philosophy and natural history), Copernicus (astronomy), Leonhard Fuchs (botany and medicine), Conrad Gesner (botany, zoology, and classics), and Agricola

(mineralogy). At the expiration of the 16th century few of the great scholars of Germany were left, and classical culture was declining in the early part of the 17th. The numerous universities and schools which had sprung up under the influence of the reformation were no longer animated by the zeal of the reformers, but engrossed by subtle polemical and scholastic strifes. The deliverance of the German intellect from the scholastic bonds of the middle ages, which was the cherished endeavor of Luther, was again retarded.—Poetry, in passing from the *Meistersänger* to scholars, lost in naturalness what it gained in elaboration. Most aspirants to poetical fame in the 17th century were graduates of universities, and learned societies were formed at the beginning of the century, with a view of improving the German language and literature. These societies became as notorious for their imitations of the Italian academies as the corporations of the *Meistersänger* had been for attempting to mimic the minstrels. After their dissolution they were replaced by many literary and scientific associations in Leipsic, Berlin, Hamburg, Königsberg, Halle, and in other of those principal central and university towns of Protestant Germany which had become the leaders of German culture. A new school of poetry was established, of which the forerunners were Friedrich von Spee (1592–1635) and Georg Rudolf Weckherlin (1584–1651), the first author of sonnets in German. Martin Opitz (1597–1639) became the leader of this school, which after his native country was called the first Silesian school. He wrote the language with a purity of idiom in which he was only excelled by Luther. He imparted more vigor to the versification, laid down the laws of metrical composition, composed for the first time an ode in German, and wrote many lyrical, mixed, and didactic poems. Although more scholastic than poetical, he exerted a great influence on literature, at a time when the 80 years' war and the growing taste for bad Italian and French modes of composition threatened to annihilate all vestiges of pure German poetry, and when the reforms introduced by Luther into the language still required to be steadily urged and followed up in order to become established. Paul Flemming (1609–'40) was the principal lyrical, and Simon Dach (1605–'59) a gifted sentimental poet of this school. Von Zesen (1619–'89) was the greatest purist of them all, strenuously opposing the admixture of French words, which was becoming more and more common in Germany. Halsdörfer was one of the principal poets of the pastoral Nuremberg branch of the school. Among the other eminent poets were Christian Weise, who excelled in popular songs and the drama, and afterward opposed the Silesian schools, and Friedrich von Logau (1604–'55), a witty epigrammatist. Andreas Gryphius did much to improve the German drama, and his poetry was as excessively passionate as that of Opitz was conventional and cold. This conven-

tionality gave rise to a formidable opposition, at the head of which stood Hofmannswaldau (1618–'79) and Lohenstein (1685–'83), who took the most inflated Italian and French writers as their models, and became proverbial for bombast and artificiality. They in their turn were opposed by Canitz, the Berlin statesman and poet (1654–'90), Besser (1654–1729), and König (1688–1794), most of whom were court poets, who endeavored to imitate the then fashionable verses of Boileau, but were unable to resist the success of Lohenstein's affected and extravagant effusions. Imitativeness was the bane of literature in Germany; only a few, as Brookes of Hamburg (1680–1747) and Günther (1695–1723), were free from it, while Neukirch (1665–1729), and especially Wernike of Hamburg (died about 1720), were almost the only poets who dared to protest against it.—The most successful authors of novels in this period were Buchholz, Von Zesen, Ziegler, Klipphausen, Lohenstein, and the duke Anton Ulrich of Brunswick. The most entertaining book of the century was a collection of tales of adventures (*Simplicissimus*), by Grimmelshausen, a style of composition in which he had been preceded by the satirist Moscherosch. The writings of the Roman Catholic preacher Abraham a Sancta Clara (1642–1709) are distinguished by a broad humor, especially his *Judas*. Among the prose writers of the 17th century were Pufendorf in political philosophy, Kepler (who wrote in Latin) in astronomy, and Gottfried Arnold in ecclesiastical history. Among writers on theology and ethics, Spener, the founder of Protestant pietism, takes a prominent position; next, his pupil Hermann Francke, founder of the Halle orphan asylum; Scriber, Schupp, Lassenius, also Butschky, and above all the celebrated Reimarus. In philosophy and learning Latin continued to be the sole medium of literature; and Jakob Boehm (1575–1624), the great mystic, stood for a long time almost alone in the use of the vernacular tongue, until the latter part of the century, when Leibnitz (1646–1716) and Christian von Wolf (1679–1754) appeared. Christian Thomasius (1655–1728), the able jurist and pietistic philosopher and writer, was the first (in 1688), in his lectures at Leipsic and afterward at Halle, to substitute the German for the Latin language as the medium of instruction. He was also among the very first to use the German language in his writings, and established the first German learned periodical in Leipsic (1688–'90). Leibnitz was the first to lay a scientific basis for the study of philosophy in Germany, but his works were chiefly written in Latin and French. Wolf, his disciple, shaped the views of Leibnitz into a comprehensive system, and published his works in the German language.—Under the impulse of the new philosophical ideas, Germany became in the 18th century excited on the subject of literature, as it had been on that of theology in the 16th. The century opened with the foundation of the Berlin academy by Leibnitz (1700). The general clamor was for reform in education, in literature, and soon for reform in all departments

of thought. Gottsched in Leipsic (1700-1766), laboring in the same direction as Thomastius, exerted himself to make the German language the sole medium of instruction, and published in it manuals and abridgments of philosophy and science. He advocated the classical rules of composition of Racine and Corneille, but aimed above all at correctness. His views brought him into conflict with Bodmer (1698-1788), and Breitinger of Zürich (1701-'76), who were admirers of Milton and rigidly orthodox in religion, while Gottsched was friendly to Voltaire. They carried on a paper war in their respective journals, until at length many who had rallied round Gottsched became disgusted with his pedantry, and separating themselves from him, established a periodical celebrated in German literature under the name of *Bremer Beiträge*, edited by Gärtner (1712-'91), in which they opposed their former friend; at the same time they formed a poetical union to which Hagedorn was friendly, although he did not join it, but which was eventually joined by Klopstock, who became its hero. Among the contributors to this journal were Rabener (1714-'71), a popular satirist, of a correct and easy style; Zachariae (1726-'77), a writer of poetry in imitation of Pope's "Rape of the Lock;" Gellert (1715-'69), a famous fabulist; Kästner, the poet and mathematician; Gieseke; Johann Elias Schlegel, dramatist, and Johan Adolph Schlegel (1721-'98), poet; Fuchs; Oramer; Ebert, translator of Young's "Night Thoughts," and several others. The journal was printed in Bremen, but the poets resided for some time at Leipsic, whence they adopted the name of the second Saxon school, while the followers of Bodmer of Zürich styled themselves the Swiss school. Related to the latter was the school of Halle, to which belonged Lange, Pyra, Uz, Götz, &c. The most distinguished of the poets of this school were Kleist (1715-'59), author of descriptive and picturesque poetry in the manner of Thomson and Pope, and Ramler (1725-'98), a composer of odes, and the first to introduce the language, versification, and manners of the ancients into Germany. Gleim, or Father Gleim (1719-1808), the celebrated fabulist and poet, at first a follower of Bodmer, gathered a nucleus of writers around him, and exercised for about 40 years a considerable influence on German poetry; but his fame was diminished by the criticism of Herder. Salomon Gessner of Zürich (1730-'87) gained in his time a high reputation as a writer of idylls, but Herder thinks that he was overrated by his contemporaries. Bodmer's prestige was also soon broken by the criticisms of Lessing. Of greater influence than any of the poets as yet named were Hagedorn of Hamburg (1708-'54), whose fables and songs have immortalized him in Germany; and Albert von Haller (1708-'77), the illustrious physiologist and savant, who was remarkable as a writer of descriptive and didactic poetry. They were followed by Klopstock (1734-1808), whose "Messiah" made a profound impression upon the religious world by its mystic, devout, and rapturous faith, while as a work

of art it was thought to rival Tasso's and Milton's epics. The fashionable and elegant portion of society was attracted by the semi-Grecian, semi-Parisian muse of Wieland (1733-1818). But it was reserved for Lessing (1729-'81) to give a new direction to German literature. He did for it what Luther had done for the German language. He established a new school of criticism, and struck a final blow at Gallic influence, at the same time that Frederic the Great was coquetting with the French graces. His tragedy *Emilia Galotti*, his comedy *Minna von Barnhelm*, and his philosophical drama *Nathan der Weise*, are models of dramatical composition. He exerted a powerful influence on the progress of the German drama by unfolding for the first time all the beauty, vigor, and originality of Shakespeare before the German mind, and by the profound and philosophical criticisms in his *Dramaturgie*. He pronounced a condemnatory judgment upon all foreign models except Shakespeare and the ancients, and demonstrated that the spirit of the age shrinks from the mediæval sentimentality of epical poetry, and desires literature to reflect its own stirring energies, as the drama alone can do. Most celebrated among the many literary publications which were identified with Lessing's critical labors, was a periodical (*Literaturbriefe*) which he founded in Berlin in 1759, in conjunction with Nicolai (1733-1811), the publisher and author. Lessing was the master spirit of this publication, and the principal contributor next to himself was his friend Moses Mendelssohn (1729-'86). Both Klopstock and Wieland were criticized in that periodical, and it was the first to discover the merit of Winckelmann the archæologist, of Hamann the mystic philosopher, and the philosophical genius of Kant, although at that time he had only written some short treatises. Shortly after the commencement of this journal, a new influence was infused into the literary world by Herder (1744-1803), who while at Königsberg became acquainted with Hamann and Kant, and who was known as a scholar as early as 1762. He brought to bear upon literature an almost universal knowledge, the study of the poets of all nations, an intimate acquaintance with Hebrew, Greek, and Latin writings, and above all a cosmopolitan humanitarian spirit, which, together with his poetical genius, manifested itself most suggestively in the crowning work of his life, *Ideen zur Philosophie der Geschichte der Menschheit*. He contributed powerfully to promote the study of oriental poetry, and was the first to call attention to the beauty of the ancient popular songs of different nations, and particularly of his own. The earnestness and dignity of his character exercised at the same time a strong influence upon the great poets of his time, and he succeeded in imbuing other minds with his poetical conceptions, both by his personal intercourse with them and by his varied contributions to literature. Another great impulse was given by

Winckelmann (1717-'68). His examinations of the remains of ancient art and his writings modified all the old theories of the beautiful; and by his efforts, combined with those of Lessing, whose celebrated work *Laocoon* was elicited by Winckelmann's suggestions, the spirit of art and poetry was brought back to the genuine and simple taste of the Greeks. Heyne, the accomplished critic and commentator, propounded the theories of Winckelmann at Göttingen, then the most brilliant university of Germany. The young men there became deeply impressed with the new theories, and, under the influence of the reforms which were then initiated in religion, philosophy, literature, art, and education—in almost all departments of thought and life—founded in 1770 the *Musenalmannach*, a literary journal, and not long afterward a poetical union known as the *Göttinger Dichterbund*, or *Hainbund*. Klopstock became the leader and model of these enthusiastic youths, whose aim was to give a new stimulus to poetic emulation, and to oppose to conventional theories a school of poetry founded upon the inspiration of genius and humanity. Among the members of the union were Bürger (1748-'94), the author of *Lenore*, and of other wild and picturesque ballads and songs; Voss (1751-1826), one of the most learned and eloquent philologists of his day, immortalized by his translation of Homer, and the author of one of the best German idyls (*Luise*); Hölty (1748-1776), whose songs became exceedingly popular; the two Stolbergs, who coöperated with Voss in familiarizing the Germans with the ancients, and who excelled in various kinds of metrical composition; Claudius, Miller, Hahn, Cramer, Gotter, Boje, &c. A genial poet of this period was Pfeffel (1786-1809), whom however it would be difficult to class with any particular school. Goethe (1749-1832), already known to fame, and acquainted with Herder and other poets, but keeping himself aloof from all unions and parties, came forward in 1778 with *Göts von Berlichingen*, which was greeted as the commencement of an entirely new period in German dramatic literature. In 1774 appeared *Werther's Leiden*. The reformatory period of literature was now over. The revolution had set in, or the *Sturm- und Drang-Periode*, as it was called after a drama of that name by Klinger (1753-1831), whose high-wrought tragedies and novels, as well as the writings of Schubart (1789-'91), Heinse (1746-1803), Lenz (1750-'92), and Müller (1750-1825), reflect most forcibly the excitement of this epoch. In the mean time Schiller (1759-1805) produced his *Räuber*, followed by *Fiesco* and *Cabale und Liebe*. These impassioned tragedies gave a new impetus to the literary excitement. His *Don Carlos*, however (1784), shows greater moderation, and opens a long series of tragedies, in which the highest aspirations for liberty and humanity are interwoven with historical associations, expressed in language of the most classical purity. But it was only

after Schiller's union with Goethe (1795) that by their combined labors German literature was brought to that classical perfection which, from a purely local, has since given to it a universal influence. Schiller, by his enthusiastic and sympathetic eloquence and tenderness, became the favorite of the people; and Goethe, with his many-sided intellect and boundless sensibilities, controlled by a strong will, enclosed in a body of exuberant health and disciplined by an all-embracing culture and knowledge, became the acknowledged sovereign of German literature.—While this golden era of letters was in a great measure accelerated by the philosophic spirit of the age which had prompted the labors of Lessing and the other reformers, that spirit itself gathered strength from the light which it diffused, and in rapid succession gave birth to Kant (1724-1804), Fichte (1762-1814), Hegel (1770-1831), and Schelling (1775-1854). Lessing, especially, by his comprehensive essay on the "Education of the Human Race," Herder, Moses Mendelssohn, and Hamann are all philosophical writers of great eminence. In a popular style wrote Engel, the author of *Lorenz Stark*, and the psychological novels of Jacobi are among the most suggestive of German prose writings. Among other prose writers are Reinhold and Barth; Alexander Gottlieb Baumgarten, the founder of the science of aesthetics (in Latin); Meier, the German interpreter of his theories; and Sulzer, who wrote on the same science. Abbt, Garve, Liscow the philosopher and elegant fabulist, Lavater the physiognomist, his friend Zimmermann, and his sarcastic and polished opponent Lichtenberg; the historians Dohm, Möser, Schröckh, Schlözer, and Beck; Spittler, the celebrated Göttingen historian; Johannes von Müller, the historian of Switzerland, and one of the classical historiographers of Germany (1752-1809); Georg Forster, the teacher and friend of Alexander von Humboldt, an admirable writer, who opened the path of scientific study in German literature; the publicist Friedrich Karl von Moser; the educator Basedow, and afterward Pestalozzi; Campa, the writer of books for children; Nicolai, the friend of Lessing and author of the satirical novel *Sebalduß Nothanker*; Adelung, the philological writer; Böttiger, the antiquary; Sturz, the biographer; Mosheim, the ecclesiastical historian; Jerusalem, Spalding, Michaelis, Rosenmüller, and Ernesti, in theology; Eichhorn in theology and universal and literary history; Blumenbach, Herschel, Euler, Vega, and many other eminent writers in various branches of learning and science, belong to this period.—A peculiar and powerful writer, who stood quite alone in his idiosyncrasies, was Jean Paul Friedrich Richter (1763-1825). He puzzles the reader by his inability to assort his thoughts, which he pours out with the reckless *naïveté* of a childlike soul; but the obscurity is lighted up by flashes of humor and brilliant gems of thought and feeling. The influence of this genial philosopher was great, especially upon the women of Germany.

Novalis (Von Hardenberg, 1772-1801) was another strangely constituted writer, who uttered himself in poetic sighs rather than in vigorous words; but amid his morbid sentiments are scattered thoughts of such wisdom and spiritual insight that his poems and prose writings, although few and fragmentary, were sufficient to assign him a place among the classical writers and poets of Germany. He is regarded as the head of the so called romantic school, which draws its inspiration from the fabulous, mediæval, and chivalric eras of literature and history. Among the most brilliant masters of this school was August Wilhelm von Schlegel (1767-1845), the author of an antique tragedy, *Ion*, and of romances and elegies, but chiefly distinguished for his admirable metrical translation of Shakespeare, his critical and æsthetic writings, his lectures on the drama and its literature, and his labors connected with Indian literature and the Sanscrit language. His brother Friedrich von Schlegel (1772-1829) was also engaged in the study of Hindoo literature; but his speciality was the history of ancient and modern literature and the philosophy of history. The most original representative of this school was Ludwig Tieck (1773-1853), whose poetical dramatization and collection of ancient fairy and popular tales reflect the romance of mediæval poesy with beauty and genius, but with a mystic feeling bordering almost on superstition. Shakespeare and Camoëns are the heroes of his most celebrated novels. The writings of Tieck's friend Wackenroder (1772-98) were the first to enlist the sympathies of the German artists for the æsthetic principles of the romantic school. La Motte Fouqué (1777-1843) stands alone in German literature by his remarkable power of giving Ariel-like delinations of the mysteries of fairy lore, instinct with grace, loveliness, and spirituality, as for instance in his tale of *Undine*. Chamisso (1781-1838), the author of *Peter Schlemihl* and of many fine lyrics; Tiedge (1752-1841), the author of *Urania*; the Aristophanic Platen (1796-1835), and the mystic religious poems of Werner, all belong to this romantic school; and with but few exceptions, as for instance the patriotic and spirited poet Seume (1763-1810), most writings of this period are tinged with a morbid passion for romantic and sentimental views of life. This epoch comprises the lyrical poets, Schenkendorf (1788-1817), Stagemann (1768-1840), Kosegarten (1758-1818), Baggesen the Dane (1764-1826), Matthiessen 1761-1831), Mahlmann (1771-1826), Salis (1762-1834), and Eichendorff (1788-1857), many of whom belong to the romantic school. Among novelists and tale writers are Achim von Arnim (1764-1831) and Clemens Brentano (1777-1842), the compilers of a series of celebrated popular songs (*Des Knaben Wunderhorn*), and Ernst Theodor Amadeus Hoffmann (1776-1822), the author of many wild, fantastic tales and legends (*Elixir des Teufels*, *Kater Murr*, &c.) which cap the climax of the supernaturalistic element of the romantic school.

Among favorite novelists of this period are S. T. Hermes (1738-1821); Hippel (1741-'96), the indiscreet friend and disciple of Kant; Musæus (1735-'87), the author of a collection of *Volks-Märchen* or popular fairy tales; Lafontaine (1759-1831), a type of the most sentimental novelists; Aloys Blumauer, Johan Gottwerth Müller, and Moritz August von Thümmel (1738-1817), the author of an excellent novel in imitation of Sterne's "Sentimental Journey;" Jung Stilling (1740-1817), the tailor in whose naïve and original autobiography Goethe, Schiller, and Herder took so much interest; Knigge (1752-'96), the author of the *Reise nach Braunschweig*; and Immermann (1795-1840), the author of the famous novel *Münchhausen*. Ghost stories were for a time made popular by Schiller's *Geisterseher*. Associated with the romantic school, in the earlier part of her literary career, was Bettina von Arnim (1785-1859), celebrated by her correspondence with Goethe. Rahel, the wife of Varnhagen von Ense (1771-1838), was another literary woman of great talent and originality of thought. Among other renowned authoresses are Auguste von Paalzow, Ida von Hahn-Hahn, Fanny Lewald, Amalie Schoppe, Johanna Schoppenhaner, Friederike Brun, and many others. Talvj (Mrs. Robinson) has contributed to diffuse a knowledge of Servian popular songs and of Slavic literature generally, and has won great distinction in this and other spheres of literature.—The efforts of Klopstock, Herder, and other authors to revive the popularity of the early German poetry, as well as the sentiment of nationality which was roused at the beginning of this century by the aggressive policy of Napoleon I., have contributed to give a powerful impulse to the researches into the ancient German literature, which was to some extent fostered by Jahn's spirited work on *Deutsches Volkthum*. Von der Hagen, by his edition of the *Nibelungen*, has done much to promote a love for the study of the old German dialects and the poetry connected with them. The brothers Wilhelm and Jakob Grimm are the more immediate founders of this new branch of philological and poetical investigation. Georg Friedrich Benecke, Karl Lachmann, and Simrock labor in the same direction, and more recently Moritz Haupt; also Franz Pfeiffer, Oskar Schade, Zarneke, Holzmann, Hoffmann von Fallersleben, Bartsch, &c.—The German war of independence against Napoleon I. produced some striking patriotic songs from Prof. Arndt of Bonn (born 1769), who in 1859 still sang against Napoleon III., and Theodor Körner (1791-1818), the gallant soldier-poet, and author of *Leier und Schwert* ("Lyre and Sword"). Some of the lyrical poets of the romantic school whom we have named also became distinguished for their patriotic effusions, especially Schenkendorf and Stagemann. Wilhelm Müller of Dessau (1794-1827), author of the admirable *Griechen-Lieder*, may be classed among patriotic poets. The maiden efforts of Fried-

rich Rückert (born 1789), one of the best lyrical and didactic poets of Germany, and celebrated as much for his imitations of troubadour songs as for his versions of oriental poetry, were also inspired by the war against the French. Another who came forward as a champion of national independence was Ludwig Uhland (born 1787), the veteran chieftain of the modern Swabian school, and one of the greatest living poets of Germany. Stuttgart, the seat of the great publishing house of Cotta and of the eminent critic Wolfgang Menzel, is the headquarters of this school. Johann Peter Hebel (1760-1826), whose *Alemannische Gedichte* were greatly admired by Goethe, belongs to it by the Swabian dialect and spirit of his songs, although he lived at an earlier period. One of the most eminent lyrical poets of this school is Justinus Kerner. Gustav Schwab, Gustav Pfizer, the critic and historian, Karl Mayer, Eduard Mörike, all belong more or less to the Swabian school. A new direction was given to literary activity by the political excitement immediately preceding and succeeding the French revolution of 1830. Ludwig Börne (1786-1837) and Heinrich Heine (1800-1856) are regarded as its heralds, the former by his pungent and comprehensive political satires, the latter by his penetration and philosophical insight and by his peculiar lyrical genius. Heine exercised a great general influence in the literary world. As a poet, he had a peculiar gift of uniting the tragic and comic in a felicitous and racy manner, which made him the idol of a new school of authors who style themselves "Young Germany," but who inherited much less of Heine's poetical gifts than of his political sympathies. Karl Gutzkow (born 1811) is the present head of this school. He is the author of *Die Ritter vom Geiste* (8d ed. 1854) and *Zauberer von Rom* (vol. 1, 1858, to be continued), and of many other political novels, and is one of the most active dramatists, *littérateurs*, and journalists of Germany; but he is more remarkable for talent and liberal aspirations than for genius. The other principal representatives of "Young Germany" are Heinrich Laube (born 1806), Gustav Kühne (1806), and Theodor Mundt (1808). An eminent author of this period is Baron Sternberg (1806), author of *Diane* and of *Paul*, and of many other works which hold up the mirror to the social and political condition of his country. Another famous writer and amateur liberal politician of this class is Prince Pückler-Muskau (1785), author of *Briefe eines Verstorbenen*, and of other piquant books. The taste for novels of a political and social tendency has been characteristic of German writers since the early part of this century. The novels of Gutzkow, Laube, and of many other contemporary German writers, all belong to this category, while Gustav Freytag has recently (1858) gained a high reputation by a social novel, *Soll und Haben* ("Debit and Credit"). The line of historical novelists was opened by Meissner (1758-1807); he was followed by Karoline von Pichler (1769-

1848), Von Tromlitz (Von Witzleben), 1773-1839), Van der Velde (1779-1824), Karl Spindler (born 1796), author of the *Jude*, the *Bastard*, and other novels, which enjoy a great popularity; Ludwig Rellstab, Ludwig Storch, Heribert Rau, and Heinrich Joseph König (born 1790), author of one of the best recent historical novels, *Die Clubbisten in Mainz* (1847). Berneck or Bernd von Guseck (1808), Theodor Mütge (1806), author of *Toussaint* and of other excellent novels, Gustav Kühne and Robert Heller (1818), are all contributors to this class of novels. A far higher merit must be awarded to Zachokke (1771-1848), one of the best German prose writers of recent times, and author of many excellent historical and romantic works, and of *Stunden der Andacht*, a religious work, which has passed through some 80 editions. Heinrich Steffens, the Norwegian philosopher and naturalist (1773-1848), wrote German novels based upon Scandinavian history, which are replete with interest. The historical novelist, however, who excels all his contemporaries in poetical wealth and in classical attainments, is Wilhelm Haring, known by the pseudonym of Willibald Alexis (born 1793), who imitated so skillfully the manner and style of Sir Walter Scott that several of his works were translated into foreign languages and passed for some time as the productions of the great English romancer. The most famous of the kind is "Walladmor." Hauff, a genial novelist; Clauren, a licentious writer, but whose novels have been read extensively; and Hackländer's *Soldatenbilder* and other sketches, may be mentioned here; also Berthold Auerbach (1812), who in his "Black Forest Village Stories" has pointed out a new direction in the delineation of the life of villagers. The Swiss author Bitzius (Jeremias Gotthelf) labors in the same direction, but his writings are didactical. Stifter and Komperdt are also popular novelists.—Among the poets who have expressed liberal political tendencies with most point, are Hoffmann von Fallersleben, the author of *Unpolitische Lieder*; Georg Herwegh, author of *Gedichte eines Lebendigen*; Franz Dingelstedt, author of *Lieder eines kosmopolitischen Nachtwehlers*; Reinhard Ernst Prutz (born 1810); Gottfried Kinkel (1815), author of fine epic-lyrical poems; and Freiligrath, author of highly original poems, descriptive of tropical scenery, and of many popular songs. Among other poets of the present time who have acquired some eminence are Grabbe, Gottschall, Emanuel Geibel, Redwitz (author of a romantic epic, *Amaranth*), Paul Heyse (author of a poetical tale, *Urika*), Wolfgang Müller, Max Waldan, Bodenstedt (especially distinguished for his versions of Persian poetry), A. Böttger, K. Simrock, Fr. Kugler, Keller, Scheffer, and Hammer, many of whom excel in ballads and songs after the style of the Swabian school. A circle of poets in Vienna cluster round Anastasius Grün (Count Auerperg), the author of *Spaziergänge eines Wiener Poeten*, Schütt, *Der letzte Ritter*, &c. Lenau and Karl

Beck were the principal and most gifted of his followers. Alfred Meißner and M. Hartmann belong to this school.—Dramatic literature has also fallen from the high estate which it had reached through Lessing, Goethe, and Schiller. Gerstenberg (1787–1823) was the author of the high-wrought tragedy *Ugolino*, noticeable only for its extravagance. Among his contemporaries were some excellent dramatists and poets, as Cronegk, Leisewitz, Ch. F. Weiss, &c. Iffland (1759–1814), in a long series of plays, has reflected the life of respectable people of the middle classes; they are eminently moral in their tone, but intolerably long and heavy. Werner (1768–1823) became the founder of the so called tragedy of fate (*Schicksalstragödie*) by his piece called *Der Vierundzwanzigste Februar*. The imitators of his extravagant style are Müllner (1774–1829) in his *Schuld*, Howald (1778–1845) in his *Bild*, and Grillparzer (1791) in his *Ahnfrau*. Kotzebue (1761–1819) was one of the German writers for the stage who succeeded in obtaining a higher popularity than all his contemporary playwrights. His forte was in comedy. He wrote more than 200 plays; some of them have been adapted to the English and French stage. Münch-Bellinghansen (*nom de plume*, Friedrich Halm) has written an excellent drama, *Der Sohn der Wildnis*, and a national tragedy, *Der Fächer von Ravenna*. Maltitz, Eichendorff, Julius Moser, Gutzkow, Laube, Hebbel, Griepkenr, Prutz, and Brachvogel, have all cultivated dramatic literature. Charlotte Birchpfeifer has dramatized a great number of stories. Karl Immermann (1796–1840) belongs to a higher class of dramatists. His trilogy *Alexis*, and his mythical play *Merlin*, and many of his tragedies and comedies, are excellent reading plays, but they are not well suited to the stage. M. Beer's *Struensee* is also a work of high poetical merit. Raupach (1784–1852) was one of the most fertile of German dramatists. Eduard Duller (1809–1853) has written several historical dramas. The comedies of Hackländer, and particularly of R. Benedix, display considerable ability; and among other writers of comedy are Feldmann, Töpfer, Albin, Gutzkow, Gustav Freytag, and above all, Bauernfeld.—Belles lettres, on the whole, have fallen into insignificance in Germany since the death of Goethe (1832). The most eminent minds of Germany no longer devote themselves to poetic and dramatic literature, but to the exploration of the spheres of science and learning. Alexander von Humboldt (1769–1859) gave a powerful impulse to almost all departments of knowledge by his "Cosmos," by his "Travels," by his "Views of Nature," and by the general suggestiveness of his labors. While he marks a new epoch in the pursuit of the natural sciences, another great movement was initiated in historical researches by Niebuhr (1776–1831), the illustrious historian of ancient Rome; Schlosser (born 1776), the vigorous and truthful exponent of universal history, and particularly of the history of the 18th century; Heeren (1760

–1842), the investigator of history in connection with political and commercial relations; Ranmer (born 1781), the historian of the Hohenstauffen; Leopold Ranke (1795), the historian of the popes; Dahlmann (1785), the German Guizot, author of "Sources of German History," and the historian of Denmark and of the English and French revolutions; Gervinus (1805), the historian of German literature, and author of the history of the 19th century; and Rotteck (1775), whose excellent universal history has been very popular on account of its liberal political views. While Niebuhr introduced a profounder method in the study of early Roman history, Bunsen, Lepsius, and others, made discoveries in Egyptian and oriental history, and a third impulse proceeded from the active researches in the field of classical archaeology and philology. These combined influences are more or less manifest in the labors in ancient history of Böckh, Karl Otfried Müller, Düncker, Droysen, Mommsen, Kortüm, Adolph Schmidt, Plass, Wachsmuth, Tittmann, Flathe, Manso, Abeken, &c. The history of the middle ages has been treated by Rüh, Rehm, Wilken, &c., and more especially by Leo, Hammer, Fallermaier, Aschbach, Lappenberg, Dahlmann, Schäfer, Röpell, &c. Oriental history and literature have been actively explored by Joseph von Hammer-Purgstall (1774–1856), author of *Geschichte des Osmanischen Reichs*, *Geschichte der Osmanischen Dichtkunst*, *Literaturgeschichte der Araber* (1850–'57,) &c. Lappenberg's History of England (3 vols., 1834–'37) has been continued by Dr. Reinhard Pauli. The 5th vol. appeared in 1858. This work is highly esteemed, as is Karl Friedrich Neumann's history of the English empire in Asia (Leipzig, 1858). Among writers on modern history are Dohm, Saalfeld, Bülow, Münnich, &c. The humanitarian and cosmopolitan direction given to historical studies by the writers and philosophers of the 18th and 19th centuries, and especially by Herder and Kant, is manifest in the comprehensiveness of views which Rotteck, and especially Schlosser, bring to bear upon their labors, as well as in many works on particular sections and occupations of the people. This has culminated in what may be designated as a new science, which the Germans call *Culturgeschichte*, i. e., a history which treats of the moral, intellectual, social, and politico-economical, as well as political development of the people. Among the principal laborers in this new sphere of investigation are Ernst Wilhelm Gottlieb Wachsmuth (born 1784), author of *Europäische Sittengeschichte* (1831–'9), and of *Allgemeine Culturgeschichte* (1850–'52); Johannes Scherr, author of *Geschichte deutscher Cultur und Sitte* (1852–'3, 2d ed. 1859); and Friedrich Gustav Klemm (born 1802), author of *Allgemeine Culturgeschichte der Menschheit* (1842–'52), and of *Allgemeine Culturoissenschaft* (1st and 2d vols., 1854). The same tendency to dwell upon the practical realities of life extends over many other departments of literature in Germany, and

is most strongly expressed in many recent biographies and autobiographies, especially in that of Perthes. A more physiological method in these branches of investigation has been adopted by Riehl in his *Naturgeschichte des Volks als Grundlage einer deutschen Socialpolitik* (3 vols., 1853-'5). A periodical for *Deutsche Culturgeschichte* was established in 1856 by Müller and Franke in Nuremberg, and a union for the promotion of this science in Weimar in 1857. Nuremberg has also been since 1857 the seat of a new national institution (*Germanisches Museum*) founded in 1853 for the promotion of researches in ancient German history and archæology, which are likewise calculated to throw more light upon the *Culturgeschichte* of the people.—The literature of travels was greatly stimulated by Johann Georg Adam Forster, commonly called Georg Forster (1754-'94), who accompanied Cook on his 2d voyage round the world, and who, in Alexander von Humboldt's opinion, inaugurated a new era of scientific voyages. A still more powerful impulse was given by Humboldt himself (1768-1859), by his travels in central Asia, &c., and by his famous journey to the equinoctial regions of America, in which Aimé Bonpland (1773-1858) was his companion. The travels of Lichtenstein (1780-1857) in southern Africa are of great scientific importance. The travels of Prince Maximilian of Wied (born 1782) have furnished valuable additions to the knowledge of the natural history and ethnology of Brazil and the United States. The explorations of Martius (born 1794) in Brazil are important for the studies of botany, ethnology, geography, and statistics. Pöppig (1797) has visited Chili, Peru, and the river Amazon. Among the other explorers of South America are Hermann Burmeister (1807), the historian of the creation, who travelled more particularly in Brazil, and Johann Jakob von Tschudi (1818), a relative of Friedrich von Tschudi, author of *Das Thierleben in der Alpenwelt*, and an active traveller, especially in Peru. Sir Robert Hermann Schomburgk (1804), a German by birth, but employed in the service of the British government, has travelled in British Guiana, Barbados, Hayti, &c. His works were published in German by his brother, Otto Schomburgk (1810-1857). Another brother, Moritz Richard Schomburgk, travelled in British Guiana at the expense of the king of Prussia, and is now in Australia in company with a 4th brother, Julius Schomburgk. The East has been visited by Gotthilf Heinrich von Schubert (1780), especially Egypt, Palestine, and Greece, and by Ulrich Jasper Seetzen (1767 to about 1815), whose *Reisen durch Syrien, Palästina, die Trans-Jordan-Länder, Arabia Peträa, und Unterägypten*, were edited by F. Kruse and published in Berlin, 1854-'9. The learned baron Heinrich Menu of Minutoli (1772-1846) wrote on his travels to Upper Egypt. Rüppell (born 1794) has explored Nubia, Kordofan, Arabia Peträa, and is best known by his travels in Abyssinia. The most eminent

writers on Egypt are Lepsius and Brugsch. Raumer (1781), the great historian, has given graphic descriptions of his travels in Venice, England, Italy, and the United States; and Joseph Russegger (1802) has written comprehensively on his travels in Europe, Asia, and Africa. Jakob Venedey (1805) has given accounts of England, Ireland, and southern France. Moritz Wagner (1818) has published his travels in Algeria, the Caucasus, Colchis, Persia, and Kurdistan, and, in conjunction with his companion Scherzer, on North America and Costa Rica. An English translation of the travels of Julius Froebel (1806) appeared in 1859 under the title of "Seven Years' Travel in Central America, Northern Mexico, and the Far West of the United States." Hettner (1821) has written sketches of his travels in Greece. Friedrich Gerstäcker (1816) is the author of many entertaining and humorous descriptions of travels, especially in the new world. Another pleasing narrator of his journeys is Theodor Mundt (1808). The most voluminous writer of travels is the tourist Johann Georg Kohl (1808). Ida Pfeiffer (1797-1868) was the most intrepid and indefatigable tourist of this or any century. Germany has also given birth to some of the most celebrated recent explorers of remote parts of the world, as Gützlaff in China, Siebold in Japan, Barth and Vogel in Africa, the brothers Schlagintweit in central Asia, and Leichhardt in Australia.—We conclude with a list of eminent men in the principal departments of learning in Germany, which includes many names already mentioned. In the natural sciences: Burmeister, Ule, Johannes Müller, Cuvier, Rossmässler, Dove, Giebel, Masius, Valentin, Moleschott, Büchner, Vogt, Oken, Burdach, Schleiden, Bernhard Cotta, Nees von Esenbeck, Leopold von Buch, Endlicher, Martius, Naumann, Bischoff, Liebig, Kopp, Poggenдорff, Rose, Erdmann, Gmelin, Wöhler, Wackenroder, Gehler, Vogel, Mitscherlich, Schödlér, &c. In medicine: Johannes Müller (1801-'58), the great physiologist and comparative anatomist, Burdach, Wagner, Ehrenberg, Hecker, Cuvier, Blasius, Froriep, Schönlein, Skoda, Dieffenbach, Gräfe, &c. In astronomy and mathematics: Bessel, Encke, Struve, Mädler, Gauss, Lejeune-Dirichlet, &c. In geography, ethnology, statistics, and travels: Karl Ritter, Scherzer, Berghaus, Petermann, Möller, Stein, Streit, Barth, Fallmerayer, Handtke, Löher, Tschudi, Raumer, Dieterich, Hübner, Sydow, &c. In history and biography: Wachsmuth, Heeren, Niebuhr, Wachler, Gfrörer, Pöhlitz, Schlosser, Rotteck, Leo, Duncker, Karl Adolf Menzel, Lappenberg, Raumer, Ranke, Dahlmann, Gervinus, Preuss, Weber, Mommsen, Prutz, Droysen, Varnhagen von Ense, Pertz, K. W. Böttiger, Zimmermann, Von Rochau, &c. In the history of literature, philosophy, and aesthetics: Gervinus, Vilmar, Wackernagel, Julian Schmidt, Solger, Bouterwek, Viascher, Schwegler, Ruge, Ferdinand Wolf (Spanish and Portuguese literature), &c. Kuno Fischer (born in Silesia in 1824), since 1856 professor of phi-

osophy at Jena, the author of *Geschichte der neuern Philosophie* (1852-'55), &c., has already acquired a high reputation as a philosophical critic and historian. In the history of the fine arts: Kugler, Schnaase, Lütke, Nagler, Stieglitz, Weigel, Waagen, Passavant, &c. In historical and German philology: Lachmann, Wachsmuth, K. O. Müller, F. A. Wolff, Schaaf, Maurer, Böckh, the brothers Grimm, Heinsius, Heyse, K. F. Becker, Maassmann, Moritz Haupt, &c. In classical archaeology and philology: Wilhelm von Humboldt, Zumpt, F. A. Wolf, G. Hermann, K. O. Müller, Niebuhr, Bernhardt, Creuzer, Wachler, Con. Schneider, Ernesti, Curtius, Matthias, Thiersch, Jacobs, Buttman, Rost, Passow, Kühner, Ramshorn, Döderlein, Freund, Gerhard, &c. In oriental and Jewish branches: Gesenius, Bopp, Freytag, Jahn, Hitzig, Hupfeld, Ewald, A. F. Hoffmann, Lassen, Von Hammer-Purgstall, Zunn, Jost, Sachs, Frankel, Geiger, Philippon, Hirsch, Grätz, Steinschneider, &c. In political sciences and jurisprudence: Savigny, Stahl, Karl Friedrich Eichhorn, Gans, Hüllmann, Welcker, Schubert, Stein, Bülow, Mohl, Gentz, &c. Jakob Joseph von Görres (1776-1848), author of many important historical, mythological, political, and polemical works, was a celebrated German publicist, and one of the most erudite men of the century. The most eminent of German bibliographers and cyclopædists was Johann Samuel Ersch. Prominent among the many-sided men of the age, and particularly distinguished for his Egyptological and historico-philosophical researches, is Chevalier Bunsen.—The principal learned periodicals are the *Göttingische gelehrte Anzeigen*; *Heidelberger Jahrbücher der Literatur*; *Gelehrte Anzeigen* and other academical journals of Munich and Vienna; *Anzeiger für Bibliographie und Bibliotheks-Wissenschaft* (Dresden, edited by Dr. Julius Petzholdt); *Serapion, Zeitschrift für Bibliotheks-Wissenschaft, Handschriftenkunde und ältere Literatur* (Leipzig, edited by Dr. Robert Naumann); *Zeitschrift für allgemeine Erdkunde*; Petermann's *Mittheilungen*; Poggendorff's *Annalen der Physik und Chemie*, and *Zeitschrift für Physiologie und vergleichende Anatomie* (founded under the auspices of Johannes Müller, edited since his death in 1858 by Prof. Peters); *Jahresbericht über die Fortschritte der reinen, pharmaceutischen und technischen Chemie, Physik, Mineralogie und Geologie* (Giessen, edited by Liebig and Kopp, with the coöperation of H. Buff, F. Knapp, H. Will, and F. Zammerlin), &c. Among the principal literary periodicals are the *Leipziger Repertorium der deutschen und ausländischen Literatur* (Leipzig, Dr. Gersdort); *Magasin für die Literatur des Auslandes* (Leipzig, Jos. Lehmann); *Minerva* (edited by Bran); *Grenzboten* (edited by Julian Schmidt and Gustav Freytag); *Deutsches Museum* (by Prutz); Cotta's *Vierteljahrsschrift und Ausland*; Westermann's *Monatshefte*, &c.—See Wackernagel, *Geschichte der deutschen Literatur* (Basel, 1851); Gervinus, *Geschichte der poetischen Nationalliteratur der Deutschen* (Leipzig,

5th ed. 1852); Eichendorff, *Geschichte der poetischen Literatur Deutschlands* (Paderborn, 1856); Julian Schmidt, *Geschichte der deutschen Nationalliteratur im 19 Jahrhundert* (3d ed., Leipzig, 1856); Vilmar, *Geschichte der deutschen Nationalliteratur* (Marburg, 7th ed. 1857); Kurz, *Geschichte der deutschen Literatur bis auf die neueste Zeit* (3 vols., 1859, not yet complete).—For German philosophy, see PHILOSOPHY; for German art, see MUSIC, PAINTING, and SCULPTURE. (See also GERMAN THEOLOGY.)

GERONA, a maritime province of Spain, in Catalonia, bounded N. by the Pyrénées, E. and S. E. by the Mediterranean, S. and W. by Barcelona; area, about 3,000 sq. m.; pop. 262,600. The surface is chiefly covered with the ramifications of the Pyrénées, but fertile valleys frequently intervene. The inhabitants of the interior are mostly engaged in agriculture and cattle-rearing; those of the coast in ship-building, fishing, and navigation. The principal rivers are the Ter, Flavia, and the Llobregat.—GERONA (anc. *Gerunda*), a fortified city of Spain, and capital of the above province, stands at the confluence of the Ter and Ona, 52 m. N. E. of Barcelona; pop. 15,000. The chief manufactures are linen and woollen fabrics, soap, earthenware, and hardware. It was captured by Charlemagne, regained by the Moors, and is famous for the sieges it has sustained, among which that by the French under Augereau, in 1809, is remarkable for the immense losses of the besiegers.

GERRY, ELBRIDGE, one of the signers of the declaration of independence, and 5th vice-president of the United States, born in Marblehead, Mass., July 17, 1744, died in Washington, Nov. 18, 1814. He was graduated at Harvard college in 1762, engaged for several years in commerce, and was elected in 1772 representative from Marblehead to the general court or legislature of the state. He at once became a political leader, an associate of Samuel Adams, Hancock, and Warren, and continued from this time almost without intermission in public life. He was placed on the two most important committees, those of safety and supplies, which sat at Cambridge, on the day preceding the battle of Lexington; and as he remained through the night, he narrowly escaped capture by the British troops. The night before the battle of Bunker hill he spent with General Warren. He was soon after appointed judge of the court of admiralty, but declined the office. In Jan. 1776, he was elected a delegate to the continental congress, then in session in Philadelphia, where he was placed on the most important committees, and was generally chairman of the committee of the treasury till the organization of the treasury board in 1780, of which he became presiding officer. He retired from congress in that year, but resumed his seat in 1788, and on his reelection in the following year was said to have been longer a member of that assembly than any other man. As delegate to the convention which met in Philadelphia in 1787 to revise the articles of confederation, he

refused to sign the constitution proposed, but lent it his support as member of congress after it had received the sanction of the people. He served 4 successive years in congress, and in 1795 retired to private life, residing in Cambridge, till in 1797 he was appointed to accompany Pinckney and Marshall on a special mission to France, to avert, if possible, a rupture between the two countries. He was invited to remain in Paris, though his associates were soon ordered to quit the territories of France, and obtained the evidence and assurances upon which the subsequent commission acted. On his return he was unsuccessfully supported by the democratic party of Massachusetts for the office of governor in 1798, and again in 1801, but was elected after a violent canvass in 1810, and was reelected in 1811. In 1812 he was elected vice-president of the United States, but died suddenly in the second year of his term.

GERSE, a department of France, bounded N. by the department of Lot-et-Garonne, N. E. by that of Tarn-et-Garonne, E. and S. E. by Haute-Garonne, S. by Hautes-Pyrénées, and W. by Basses-Pyrénées and Landes; greatest length, 73 m.; greatest breadth, 58 m.; area, 2,425 sq. m.; pop. in 1856, 804,497. This department was formed from parts of the old provinces of Gascony and Guienne. The surface is in general hilly. Among its mountains is Mont d'Astarac, 1,180 feet above the level of the sea. It is watered by the Gers, Save, Adour, and several other rivers. The most important vegetable products are wheat, maize, oats, rye, peas, beans, onions, and fruit. Large quantities of wine and brandy are annually made. The minerals are marble, gypsum, potters' clay, marl, building stone, and a fusible spar used in making glass and porcelain. The only manufactures are coarse woollens, leather, bricks, glass, and earthenware. The number of wind and water mills is said to exceed 1,000. Capital, Auch.

GERSON, a rabbi of France, distinguished by the appellations *Rabbenu* (our master), *Hassaken* (the old man), and *Moor Haggolah* (light of the exiled), flourished in the 11th century, wrote a commentary on the Talmud, and is celebrated for the introduction of various substantial reforms among the European Jews, including the abolition of polygamy and repudiation, known under the name of "institutions (*gezeroth*) of Rabbenu Gerson."

GERSON, JEAN (CHARLIER), a French theologian, born at Gerson, near Rheims, Dec. 14, 1868, died in Lyons, in a convent of the Celestines, July 12, 1429. He was the eldest of 12 children. At the age of 14 he went to Paris to study the humanities and theology, and in 1887 he was selected by the university to be one of its deputation to Pope Clement VII. at Avignon upon the controversy concerning the immaculate conception. In 1895 he was made chancellor of the university of Paris. Charles VI. had just fallen into insanity, and while divisions menaced the state, the church was rent by a schism which produced 2 and afterward 3 pretenders

to the pontifical throne. Gerson exerted himself for the reform of morals and the banishment of scholasticism from the university, combated astrology, and resisted the invasion of the pantheistic doctrines which then had their seat in Brabant. When the duke of Orleans was assassinated by the duke of Burgundy in 1408, Gerson, at the peril of his fortune and life, denounced the murderer and delivered the funeral oration of his victim. Pursued by John the Fearless, he saw his house pillaged, and was obliged to conceal himself for a long time in the vaults of Notre Dame. He took the lead both as theologian and orator at the council of Constance, assembled in 1414 for the pacification of the church. He there maintained the superiority of general councils to the popes, and urged the deposition of both John XXIII. and Benedict XIII., and the election of a new pontiff. The schism was at length ended, but his efforts to check the abuses which reigned in the church were ineffectual; and as civil dissensions did not permit his return to France, he retired in a pilgrim's habit to the mountains of Bavaria, where he wrote his "Consolation of Theology." He returned to his country after a voluntary exile of 2 years, and found an asylum in a convent. Though one of the most active men of his age, he was also the most mystical of its thinkers. The restless chief of the university of Paris, he yet professed a religious philosophy which makes the ideal of human wisdom consist in silent prayer. He was the first who sought to give to the reveries of mysticism the character of a science. He recognized in the soul two classes of faculties—the cognitive or intellectual, whose highest act is simple intuition of divine things; and the affective faculties, whose highest act is ecstatic delight in God. Faith and penitence are the two wings on which the soul approaches the Infinite Being. To substitute this mystical philosophy for scholasticism was the aim of his writings. As many manuscripts of the "Imitation of Jesus Christ" bear the name of Gerson, that work is often ascribed to Gerson. The author of the "Imitation" expressed the hope that his name should be known to God alone, and men have in vain sought for certainty concerning it. The college of the Sorbonne and the larger number of German critics have ascribed it to Thomas à Kempis; some Italian ecclesiastics and the order of the Benedictines, to a certain Gersen of the 18th century; and many French scholars, including Mabillon and Bellarmine, have pronounced for Gerson.

GERSTÄCKER, FRIEDRICH, a German novelist and traveller, born in Hamburg, May 16, 1816. He was apprenticed to a merchant at Cassel, but soon conceived the plan of emigrating to America. He devoted himself in 1835-'6 to the study of agricultural economy, and in 1837 left Bremen for New York. After his arrival, he began a wandering and adventurous life, traversing the United States in all directions, now working his passage on steamboats, now hunting in the backwoods, and

finally settled in 1843 as hotel keeper at Point Coupée, La. In Louisiana he published parts of a journal he had written for his mother, of which extracts also appeared in Heller's *Rosen* in Germany. He returned to Germany in 1843, devoted himself to literary pursuits, and published successively his *Streif und Jagdsüge durch die Vereinigten Staaten Nordamerikas* (2 vols., Dresden, 1844); *Die Regulatoren in Arkansas* (3 vols., Leipsic, 1846); *Mississippi-Bilder, Licht- und Schattenseiten transatlantischen Lebens* (3 vols., Dresden, 1847); *Amerikanische Wald- und Strom-Bilder* (2 vols., Leipsic, 1849); and several minor works. He set out in March, 1849, for new travels, and at the expense of the bookseller Cotta and the ministry of the so-called vicar of the German empire, proceeded from Rio Janeiro, via Buenos Ayres and Valparaiso, to California, thence to the Sandwich and Society islands, and to Australia, and finally returned in 1852, via Batavia, to Germany. He has since resided near Leipsic. Of his recent travels he has given accounts in the *Ausland*, and the supplement of the Augsburg *Allgemeine Zeitung*, which were collected under the title of *Reisen* (Stuttgart and Tübingen, 1853-5), and have also been translated into English. Among his other books are many popular guide books for American emigrants and translations from the English. A French translation of several of his works appeared in 1858.

GERUND, in Latin grammar, a verbal neuter noun, having only the 4 oblique cases of the singular number, which serve as cases of the present infinitive active verb used substantively, and govern the case of their verb.

GERVINUS, GEORG GOTTFRIED, a German historian and politician, born in Darmstadt, May 20, 1805. He entered a mercantile house, but determined to abandon business for study, and repaired in 1826 to the university of Heidelberg. After completing his studies, during which the lectures of Schlosser had inspired him specially with a love of history, he taught in an institution at Frankfort-on-the-Main, but soon returned to Heidelberg. He then studied several years in Italy, collecting notes and materials for historical works, and on his return to Heidelberg in 1835 was appointed extraordinary professor. He had already published a *Geschichte der Angelsachsen im Überblick* (Frankfort, 1830), and *Historische Schriften* (Frankfort, 1833), and in 1836 he was appointed ordinary professor of history and literature at Göttingen. He had now begun his important work *Die Geschichte der poetischen Nationalliteratur der Deutschen* (3 vols., Leipsic, 1835-8; 8d ed., 1846-8), the complement of which is the *Neuere Geschichte der poetischen Nationalliteratur der Deutschen* (3 vols., Leipsic, 1840-42; 8d ed., 1852). In these productions he traces the development of poetry in its relations to the progress of civilization and of society. He lost his chair at Göttingen in 1837 by being associated with Dahlmann, the brothers Grimm, Ewald, and other professors, in signing the protest

against the abolition of the Hanoverian constitution. In 1838 he made another journey to Italy, renewed his historical researches at Rome, and returned to Heidelberg, where he became honorary professor in 1844. He now took part in the political affairs of Germany, advocating liberal ideas, and published pamphlets which exerted an influence throughout the country. The Heidelberg address on the Schleswig-Holstein difficulty in 1846 was written by him. In 1847 he was one of the founders of the *Deutsche Zeitung*, the organ of the constitutional party, and as its editor-in-chief he had a prominent part in forming the constitution of 1848. A member of the diet and of the national assembly, he was more influential as a journalist than as an orator, though he engaged in the stormy debates on the constitution in Dec. 1848. In 1850 he went to England, where he made unsuccessful efforts in behalf of the duchies of Schleswig and Holstein, and on his return to Heidelberg resumed his historical writings. Among his later works is a study of Shakespeare (4 vols., Leipsic, 1849-50; 2d ed., 1850); a *Geschichte der Deutschen Dichtung* (5 vols., Leipsic, 1853); and a *Geschichte des neunzehnten Jahrhunderts* (Leipsic, 8d vol., 1858; English translation, 1859). The introduction to the last work (1858), in which he declared his republican doctrines, caused him to be arraigned before the tribunal of Baden, but the prosecution was abandoned.

GESENIUS, FRIEDRICH HEINRICH WILHELM, a German orientalist and biblical critic, born in Nordhausen, Feb. 3, 1786, died in Halle, Oct. 23, 1842. He studied at the universities of Helmstädt and Göttingen, taught at the pedagogical institute of Helmstädt, and was appointed in 1806 *magister legendi* at Göttingen, in 1809 professor of ancient literature in the gymnasium of Heiligenstadt, in 1810 subordinate, and in 1811 ordinary professor of theology in the university of Halle, where he remained to the end of his life, leaving his favorite university only for a scientific journey with Thilo to Paris and Oxford in 1820, or for short excursions through Germany. Making the study of the Semitic languages, and particularly of the Hebrew, the task of his life, Gesenius, by his numerous works, which evinced a most extensive and profound erudition, as well as by his lectures, which attracted a continually increasing number of students, succeeded in reviving an interest for this species of learning, comparatively neglected since the time of the Buxtorfs, and in founding a new school of biblical exegesis, chiefly based on an accurate, rational, and historico-critical study of philology. His works are: "Hebrew and Chaldee Lexicon for the use of the Old Testament" (2 vols., Leipsic, 1810-12; 4th German ed., 1834; 2d Latin ed., 1846; translated into English by J. W. Gibbs, Andover, 1824, and by Edward Robinson, Boston, 1850); "Elementary Course of the Hebrew Language" (2 vols.), comprising a "Hebrew Grammar" (Halle, 1818, 16th edition by Rödiger, Leipsic, 1851; trans-

lated into English by M. Stuart, Andover, 1826, and by T. J. Conant, Boston, 1839); a "Hebrew Reader" (Halle, 1814; 7th ed. by De Wette, Leipsic, 1844; 8th ed. by Heiligstedt, 1851); "Critical History of the Hebrew Language" (Leipsic, 1815; 2d ed., 1827); *De Pentateuchi Samaritani Origine, Indole, et Auctoritate* (Halle, 1815); "Grammatico-critical System of the Hebrew Language" (3 vols., Leipsic, 1827); "Translation of the Prophet Isaiah, with a Philologico-critical-historical Comment" (8 vols., Leipsic, 1820-'21); *Thesaurus Philologico-Criticus Linguae Hebraicae et Chaldaicae Veteris Testamenti* (vol. i.-iii. Fasc. 1, 2d ed., Leipsic, 1829-'42). His contributions to the cyclopædia of Ersch and Gruber, and his notes to Burckhardt's travels, are valuable.

GESNER, KONRAD VON, a Swiss naturalist, called the German Pliny, born in Zürich, March 26, 1516, died there, Dec. 18, 1565. He studied under the best masters at Zürich, Strasbourg, Paris, Basel, and Montpellier, and was successively master of a school at Basel, teacher of Greek at Lausanne, and practising physician and professor of ethics and physics at Zürich. His first important work was a *Bibliotheca Universalis* (Zürich, 1545-'9), a vast collection, containing the titles of all the books then known in Hebrew, Greek, and Latin, with criticisms, summaries, and specimens. This is among the earliest works on bibliography, and has served as a model to many that have succeeded it. In 1555 appeared his *Mithridates de Differentiis Linguarum*, having accounts of 180 ancient and modern languages. His most important work, the *Historia Animalium*, with woodcuts, was published between 1551 and 1556, and is a summary of all that was then known of zoology, of the nomenclature, description, anatomy, habits, and uses of quadrupeds and aquatic animals. He then devoted himself to botany, and in his *Opera Botanica* gave particular attention to the flower and the fruit, and suggested the possibility of a classification by means of the organs of fructification.

GESNER, SALOMON, a Swiss painter and poet, born at Zürich, April 1, 1780, died in the same city, March 2, 1788. He showed little inclination for study in boyhood, but by reading the German poets, especially Klopstock, his mind was awakened. His father attempted in vain to engage him in his own business of book-selling, and allowed him to follow his inclination for poetry and landscape painting. He resided successively at Berlin, Hamburg, and Zürich, first becoming known by his poem on "Night," which was followed by "Daphnis," a pastoral in 8 cantos, by "Idyll," the "Death of Abel," in prose, a "Picture of the Deluge," some moral tales and dramas, and lectures on landscaping. Some of the engravings with which he illustrated his poems are worthy of the first masters.

GETA, P. SEPTIMIUS. See CARACALLA.

GETÆ, an ancient people mentioned by Herodotus and Thucydides as living S. of the Ister

(Danube), and by later writers among the tribes that lived N. of that river. Some critics regard them as identical with the Dacians, others with the Goths. Rawlinson, in his notes on Herodotus (iv. 98 and elsewhere), adopts the latter opinion as almost certain, and points to the "striking analogy of the compounds, Massageta, Thyssa-getæ, and Tyri-getæ, to the later names of Visi-goths and Ostrogoths."

GETHSEMANE, a retired place, containing about half an acre of land, on the W. side of Mt. Olivet, within a stone's throw of the brook Kedron, and commanding a full view of Jerusalem. The name, from two Hebrew words (*gath* and *shemen*) signifying oil-press, indicates the fertility of the spot, especially in olives. Though called a garden, it was probably a grove, laid out with walks, and affording shade and seclusion to those who resorted thither from the city. The Saviour often retired there for devotion. There he was in his agony in prayer, immediately after the last supper; and there he was sought and found by Judas, when he betrayed him. The place contains 8 large and venerable looking olive trees, the trunks of which show their great antiquity, and of which the traditions of the region would have us believe that they are the same under which Christ walked and prayed. The spot is now sandy and barren, and appears like a forsaken place. It is surrounded by a low broken wall, and is in the keeping of a fraternity of monks. The locality intended in the Scripture narrative is in some doubt, but the one above described corresponds with the required conditions.

GETTYSBURG, a post borough and the capital of Adams co., Penn., built on elevated ground in a rich farming country, at the intersection of several important roads with the turnpike from Philadelphia to Pittsburg, 114 m. W. of the former city, and 36 m. S. W. of Harrisburg; pop. in 1853, about 3,000. It is extensively engaged in the manufacture of carriages, is mostly well built, is supplied with good water conveyed in iron pipes from a neighboring spring, and contained in 1850 a brick court house, gaol, public offices, an academy, a bank, 7 churches, and 8 printing establishments issuing 8 weekly newspapers and 1 quarterly publication. It is the seat of a Lutheran theological seminary, founded in 1825, having 2 professors, about 20 students, and 7,000 vols. in its libraries, and of Pennsylvania college, founded in 1832, and having a president and 7 professors, 60 students, a library of 9,000 vols., and a medical department in Philadelphia. The college occupies a handsome Doric building, 4 stories high and 150 feet long. Several copper mines were opened near the town in 1851. The Wrightsville, York, and Gettysburg railroad affords communication with the Susquehanna river and with the N. central railroad of Pennsylvania.

GEULINOX, ARNOLD, a Belgian philosopher, born in Antwerp in 1625, died in Leyden in 1669. He studied and taught the classics and the Cartesian philosophy at Louvain for many

years, and at Leyden abjured Catholicism and gave private lessons in philosophy. His friends obtained for him the chair of philosophy in the university of Louvain, where he taught till his death the doctrines of Descartes, of whom he was the most remarkable disciple prior to Spinoza and Malebranche. In his writings are contained the germs of some of the doctrines of these philosophers, as the confusion of will with love, the vision in God, the hypothesis of occasional causes, and the absolute unity of substance.

GEYER, HENRY SHEFFIE, an American jurist, born in Fredericktown, Md., Dec. 9, 1790, died in St. Louis, March 5, 1859. In 1811 he began the practice of the law in his native town. He was an officer in the U. S. army in the war of 1812, at the close of which he removed to St. Louis, then a frontier village, where the remainder of his life was passed. He was a member of the territorial legislature of Missouri in 1818; was 5 times elected to the legislature of the state; and was speaker of the house of representatives in the first three general assemblies after the adoption of the state constitution. As one of the revisers of the statutes in 1825, he contributed more, perhaps, than any other individual to the adoption of a system of laws in Missouri superior to that of any other western state at that time. In 1850 the post of secretary of war was tendered to him by President Fillmore, but he declined it. In 1851 he was elected U. S. senator from Missouri, to succeed Thomas H. Benton. He was at the time of his death the oldest member of the St. Louis bar, both in years and in professional standing.

GEYSERS (Icelandic, *geysa*, to burst forth violently), intermittent hot springs found in various parts of Iceland. The principal locality is in the S. W. division of the island, about 85 m. N. W. from Hecla, and 70 from Reikiavik, the chief town. Here, in a circuit of about 2 miles, it is said over 100 springs may be counted which send forth hot water, 50 or more in the space of a few acres. These are on the lower slope of a small hill of trappean rock, and above them in the steeper part of the hill under the cliffs of this rock are banks formed by the incrustations of ancient and now nearly extinct geysers. The springs are of various dimensions, and exhibit various degrees of activity; some are uniformly full and quiet, others are constantly boiling, and others only at intervals, with explosive discharges of water and steam. The vapors arising from them fill the atmosphere around, forming clouds that are seen from among the mountains miles away. They are accompanied with sulphurous odors; and the geysers of other localities upon the island are found to deposit sulphur derived from the decomposition of iron pyrites contained in the days through which the hot waters penetrate. The chief spouting springs of the group are distinguished by the names of the Great Geyser and the Little Strokr. The Great Geyser when quiet presents the appearance of a circular mound made up of silicious incrusta-

tions, enclosing a pool, the sides of which slope inward at an average angle of 18° , and outward at a mean inclination of 8° . The height of the mound on the lower side is about 20 feet, but only half as much on the upper side. Its diameter varies from 50 to 60 feet. In the centre is a well 10 feet in diameter, its mouth about 5 feet below the level of the surface of the water when the pool is filled. The total depth obtained by sounding is 78 feet below this surface. The pool is filled with water, except for 6 or 7 hours after a great eruption, by which it is emptied even to the depth of 4 or 5 feet in the well. At other times the water is constantly flowing out, at a mean temperature of 185° F. At intervals of about an hour and a half a rumbling noise is heard underground, and the water heaves up in the centre, throwing an increased quantity over the margin. The great eruptions take place at irregular intervals, sometimes exceeding 80 hours. At these times loud explosions are heard beneath the surface, the water is thrown into violent agitation, it boils furiously, and at last is suddenly sent forth in a succession of jets, which increase in force till they become an immense fountain, that is lost to view in the clouds of steam in which it is enveloped. The heights reached by these jets have been variously estimated by different travellers. The lowest estimate is 60 or 70 feet; that of Von Troil in 1772 is 92 feet; of Sir John Stanley in 1789, 96 feet; of Lieut. Ohlsen, a Danish officer, in 1804, determined by a quadrant, 212 feet; of Sir George Mackenzie in 1810, 90 feet; and of Henderson, in 1815, 150 feet. The discharge continues only about 5 minutes, when the geyser subsides to a state of tranquillity.—The Great Strokr, so named either from the Icelandic word meaning churn, or from *stroka*, to agitate, is only from 800 to 400 feet distant from the Great Geyser, from which it differs in appearance in being an irregularly formed well, incrustated with silicious deposits, but having little of the basin shape at its mouth. Its orifice is about 8 feet in diameter, diminishing to about 10 inches at the depth of 27 feet; the whole depth is a little over 44 feet. The water for the greater part of the time is 10 or 12 feet below the surface, but at intervals of half a day or thereabout it breaks forth in a great eruption like those of the Great Geyser; as observed by Henderson, this continued for $\frac{1}{4}$ of an hour, during which an eruption of the Great Geyser also took place that lasted only 5 minutes. By throwing stones into the well of the Strokr, Henderson found he could bring on an eruption in a few minutes. The Little Strokr exhibits the same phenomena upon a smaller scale. There are in the same vicinity two large and quiet wells remarkable for their beautifully blue water. These were once active, and one of them was described by an English traveller as the Roaring Geyser. It became tranquil immediately after an earthquake in 1789, when the Great Strokr first broke forth. The deposits of silica which accumulate around

the geysers are derived from the small amount of this material which is taken up in solution by the hot water. By the analysis of Dr. Black, made upon 10,000 grains (about $\frac{1}{4}$ of a gallon), it would appear that the whole amount of solid matter remaining dissolved in the cold water is only a little more than $\frac{1}{1000}$ of the whole, the quantity examined yielding as follows: soda, 0.95, alumina 0.48, silica 5.40, muriate of soda 2.46, dry sulphate of soda 1.46; in all 10.75. As the water evaporates and is chilled, the excess of silica is added to the surface around, filling the interstices of the mosses and grass, and making of these silicious petrifications, while the living plants still thrive and shoot above the strong substance that binds together their roots and stems. Where the waters are found at a temperature of 98°C . (208.4°F .), M. Descloiseaux observed that the confervæ still flourished. From the experiments of this savant and of M. Bunsen made in 1846, it appears that the temperature of the waters varies at different depths, as also at different periods between two eruptions, the changes always taking place in the same manner and with considerable regularity. Immediately before the eruptions there is a maximum temperature at the bottom of the well estimated at 260.6°F ., and a minimum immediately after of 253.4°F . The temperature of boiling water at the depth reached by the thermometer should be about 276°F . The water therefore is not thrown into ebullition at this point, but must be at some other, nearer the source of the heat, with which the geyser is supposed to be connected by a long and sinuous channel. Upon this are no doubt cavities in the upper portions of which steam collects. When an eruption has taken place, the temperature of the lower portions of the liquid column is reduced, the steam in the reservoirs has less tension than is required to counterbalance the weight of the column in the well and of the superincumbent atmosphere, and the water consequently subsides. As new steam is generated, it is for a time condensed in the water, which is below its boiling temperature, and to which it imparts its latent heat. This at last is thrown into ebullition, and the steam is accumulated in sufficient quantity to raise by its tension the column of water and project it into the air. The different sets of eruptions may be owing to the existence beneath the surface of reservoirs of different capacities and at different elevations. It has also been proposed to explain the phenomenon on the principle that water when long boiled, by the loss of the air it contains, requires a great accession of heat to throw it into ebullition, and that this is then apt to take place with a sudden production of vapor accompanied with violent explosion. It is a singular fact in the history of Iceland that no mention is made of the geysers until they are spoken of by Svenson, bishop of Skalpolt, in the 17th century; and this is the more remarkable, as Ari Frode, who wrote of the geography and history of the island in the 11th cen-

tury, spent his youth in their immediate vicinity. They bear unmistakable evidences of having been in operation in this district, if not in the exact spots where they are now found, from remote periods.—There are also geysers in California, in Napa co. about 60 m. N. of Napa City. They are formed by a number of hot sulphur springs, the water of which is continually boiling, and in several places is thrown up to the height of 10 or 15 feet.—The geysers of Iceland are treated of in the works named below: "Letters on Iceland," by Von Troil (1773); "Travels in Iceland," by Sir George Mackenzie (1810); "Journal of a Residence in Iceland during the years 1814 and 1815," by Ebenezer Henderson; "Visit to Iceland in the Summer of 1834," by John Barrow, jr.; "A Visit to Iceland," by the Hon. A. Dillon (1840); observations of M. Descloiseaux in *Annales de chimie et de physique* (April, 1847), and "Philosophical Magazine" (vol. xxx. p. 397); "Tracings of Iceland and the Farøe Islands," by R. Chambers (1856); "A Yacht Voyage," by Lord Dufferin (London, 1858).

GFRÖRER, AUGUST FRIEDRICH, a German historian, born March 5, 1803, in Calw, Wurtemberg. He studied theology at Tübingen from 1821 to 1825, was appointed in 1828 tutor (*Repetent*) in the theological seminary of Tübingen, in 1830 librarian at Stuttgart, and in 1846 professor of history in the university of Freiburg. He was also elected in 1848 a member of the parliament of Frankfort. His first work, on Philo and the Alexandrine theosophy (Stuttgart, 1835), was written from the critical standpoint of the Tübingen school; but while preparing his "History of Primitive Christianity" (3 vols., Stuttgart, 1835-'6), he changed his views on Christ and Christianity, and arrived at length, during the publication of his "History of the Christian Church" (4 vols., Stuttgart, 1841-'6), at the opinion that the Roman Catholic church is the true church of Christ; but he did not join that communion till 1853. Beside the works already mentioned, he has written a "History of Gustavus Adolphus" (Stuttgart, 8d ed., 1853); a "History of the Carlovingians of Eastern and Western Franconia from 840 to 918" (2 vols., Stuttgart, 1848); a "Primitive History of the Human Race" (3 vols., 1855); and began in 1858 a "History of Pope Gregory VII.," which is intended to be in 5 vols.

GHARA, GHARRA, or GAERRA. I. A small river of Sind, Hindostan, flowing through a low, level country, and emptying into a long creek which conveys its waters to the Indian ocean, 10 m. E. of Kurrachee. The village of Ghara in the Kurrachee district is on its bank. II. A name given to the Sutlej in the Punjab, from its union with the Beas at Endreesa to its confluence with the Obenuh, 800 m. lower down, after which it receives the name of Punjnad. Its course, though tortuous at intervals, is in general remarkably straight, its direction being nearly S. W. At Hureekes, a short distance below the mouth of the Beas, it is 600 or

700 feet wide, and about 12 feet deep, and runs with a velocity of $2\frac{1}{2}$ m. an hour. In the S. part of its course, however, it becomes sluggish and muddy, with low alluvial banks which are frequently overflowed. Its waters are of a light color, while those of the Chenaub are reddish, and for several miles below their confluence the opposite sides of the united rivers preserve the difference of hue.

GHAUTS (literally mountain pass; whence, through the Teutonic languages, the English word *gate*), the name of two ranges of mountains in S. Hindostan. The principal of these is the western, which extends N. from Cape Comorin, the southern extremity of this country, in an almost unbroken chain of remarkably uniform topography, to the river Taptee, at the mouth of which is Surat, 800 m. N. of Cape Comorin. The general direction of the chain is parallel with the coast of the Indian ocean, which it approaches in one place within 6 m.; but being for the most part at a distance of 40 to 70 m., its summits are hardly discerned from the shores. On its western side it presents a front which rises boldly from the hilly country between the ranges and the coast; but on the east it gradually slopes away, or spreads in table-land, having an average elevation of about 3,000 feet above the sea, or is continued in long spurs, which stretch out through this central region, known as the Deccan. The country on the west, called the Malabar coast, is comparatively low, its average elevation being roughly estimated at 200 feet above tide. It is hilly, but also penetrated by creeks and bays making back from the sea; and it is traversed by extensive ravines, which are shaded with forest and jungle. But few gaps break the continuity of the chain, and only one of these is deep enough to drain the waters on the E. slopes into the Indian ocean. This point is in the S. part of the range against the Coimbatore country, from which the river Ponany flows through a break 16 m. wide. Opposite this break it is thought that ships navigating the Indian ocean experience the N. E. monsoons in greater fury than elsewhere. The average height of the western Ghauts is estimated at 4,000 feet, but some of the peaks rise much higher. Bonassoon is said to be 7,000 feet high, and Dodabetta in the Neilgherries 8,760 feet. The range, though often steep and stony, is not remarkably rough nor rocky. A deep rich soil covers the surface, and even upon the summits supports stately forests, such as are found only in the tropics. The bamboo attains an unusual height, rivalling that of the lofty palms which are scattered here and there among its detached clumps. The teak forms forests upon the mountain sides, and on the lower hills in the southern district of Travancore are magnificent forests producing pepper, cassia, frankincense, and other aromatic gums. In the most elevated regions no undergrowth or jungle is encountered, but the open woods afford unobstructed passage in every

direction. Roads, however, are maintained only at great cost, owing to the violence of the torrents of water during the rainy season; hence the passes across the range are few and difficult. These are occupied by military fortresses, which, with the unhealthiness of the climate and the dangers from lurking tigers, suggest considerations little in harmony with the natural beauties of these scenes. There are, however, points among the mountains noted for their salubrity, and on this account resorted to by Europeans, as some of the Neilgherries, and the village in the Mahableshwur hills, 80 m. S. E. of Bombay, made a convalescent station in 1828 by Sir J. Malcolm. The elevation of this point is 4,500 feet above the sea.—The Neilgherries, among which are some of the most elevated peaks of the range, occupy a tract of some 700 sq. m. on the E. of the main chain N. of Coimbatore. Here the eastern Ghauts are usually regarded as diverging from the western; but some trace them further S. through the Carnatic in the range of hills which meet the western Ghauts about 20 miles from Cape Comorin. Each range extends across to the Coromandel coast, and coming together in lat. $18^{\circ} 20'$ N. the chain continues with the coast, some say even to Balasore, which is within 125 m. of Calcutta; but it is commonly regarded as running out before reaching the river Kistnah, thus limiting the eastern Ghauts to about 500 m. in length. Its hills are naked and rocky, and seldom attain the altitude of 3,000 feet. A glance at the map of southern Hindostan exhibits the chief peculiarity in the topography of the country included between the two ranges of the Ghauts and bounded on the N. by the Vindhya mountains. The drainage of this region is all toward the bay of Bengal. The greater elevation of the western Ghauts and the gradual slope of the country toward the E. and S. E. is betrayed, and the fact also that this country must be a very elevated region, as the mountains on the Coromandel coast are crossed by all these rivers far below their sources. A striking resemblance is perceived between the western Ghauts, ranging in front of the Indian ocean, and the Andes which look out upon the Pacific from the western verge of the South American continent. The long rivers commencing on their eastern slopes suggest the drifting of water-charged clouds across the range, which shed their moisture, as those driven by the trade winds discharge theirs upon the Andes. Such clouds are in fact brought alternately from either sea, as the monsoons, after setting all the summer months from the S. W., turn when the sun ceases to parch the desert plains of central Asia, and, in the regular N. E. trades, blow from the sea of Bengal upon the E. coast. The S. W. monsoons commence in May and June, with terrific storms of thunder and rain, which vent their greatest fury upon the western Ghauts. The clouds, but half discharged, are swept on over the hills of the Deccan, watering them with less copious showers. This contin-

ues until October. During this time that part of the Coromandel coast under the lee of the eastern Ghauts receives no rain; but about the mouth of the Godavery the clouds arrive still charged with it; and further to the N. they are not wholly deprived of it, until they reach the snowy regions of the Himalaya. In October these winds fail, and the regular N. E. trades or monsoons set in with terrible thunder and lightning and hurricanes on the bay of Bengal, producing while they last, which is to about the close of the year, the rainy season on the Coromandel coast and the eastern Ghauts. But under the lee of the western range this is the dry season, a season of fair weather with occasional southern gales. The quantity of rain precipitated upon the western Ghauts during the summer is unprecedented in any other part of the world in the same length of time. At the station of Mahableshwur, already referred to, it has been found equal to 289 inches. The mean annual fall upon the American continent is 89 inches. Such deluges of water pouring down the steep western slope of the range may well produce the extensive ravines which traverse the Malabar country.—In their geological structure both ranges of the Ghauts appear to agree with other great N. and S. mountain chains of the world. Their rocks are the metamorphic schists, which contain rich metals and valuable ores. Gold is found pretty generally diffused along their course, and is especially abundant in the Neilgherries. Copper ores are worked in the eastern Ghauts near the sources of the Pennar river, about 40 m. N. E. from Cuddapah. In the same region of the Carnatic, only 7 m. N. E. from Cuddapah, diamonds have been found for centuries past; and 2° further N., in the province of Hyderabad, is Golconda, celebrated of old as the depot of precious gems found in the regions watered by the Pennar and Kistnah rivers. From the table-lands of Mysore, which border the eastern Ghauts on the N. W., are brought the precious ruby, topaz, chrysolite, cats-eye, garnet, beryl, &c. The region of the carnelian is in the province of Guzerat, which is beyond the N. extremity of the western Ghauts, the outlet of which is Cambay. (See CAMBAY STONES, and CAENELIAN.) The famous diamond region of Pannah in Bundelcund, supposed to be the Panassa of Ptolemy, is also beyond the limits of the Ghauts, in the Vindhya mountains, which, stretching across central Hindostan, connect the N. terminations of the E. and W. chains. Iron ores of the richest qualities are found in abundance along the Ghauts on both sides of the peninsula of Hindostan. They are successfully worked in the rude forges of the natives in Malabar, Mysore, and Bejapoor, both into wrought iron and steel; and the bar iron of the district of Orissa, shipped from Balasora, is a merchantable article in the market of Calcutta. At Porto Novo, S. of Madras, are the extensive iron works of the East India iron company, which also has an-

other establishment at Beypoor on the opposite side of the peninsula of Malabar.

GHAZIPOOR, or **GHAZKEPORE**, a district of British India, under the Lieut. gov. of the N. W. provinces; area, 2,187 sq. m.; pop. 1,596,824, of whom 1,438,085 are Hindoos. It is bounded N. and E. by the Goggra, S. by the Gangea, and W. by the Juanpoor. It is a low, level country, diversified by many shallow lakes and well irrigated by nature and by art. The climate is healthy, except in the latter part of autumn, when fevers of a mild type prevail. The thermometer ranges from 58° to 98°. Its best known productions are rose water and attar of roses, for which many hundreds of acres of the flowers are cultivated, and its chief agricultural crops are maize, wheat, pulse, barley, oats, rice, indigo, oil seeds, gram, tobacco, opium, and sugar. Cotton is grown to some extent. Ghazipoor was anciently subject to the sovereigns of Ayodha (Oude), and after passing through the hands of those of the Kanouj, Patan, and Mogul dynasties, was seized by Surajah Dowlah, vizier of Oude, about 1761. The Mogul Shah Alum granted it in 1764 to the East India company, by whom it was relinquished to the vizier of Oude in 1765; the latter ceded it again to the British by the treaty of 1775.—**GHAZIPOOR**, the chief town of the above district, is situated on the left bank of the Gangea, 46 m. N. E. from Benares, and 431 m. N. W. from Calcutta; pop. 38,573. It stands on high ground, enclosed by beautiful groves of banyan and pipal, and is noted for its healthy climate. At its E. end is the palace of Meer Cossim Ali, nabob of Bengal.

GHEE, a kind of butter used in many parts of India, prepared generally from the milk of buffaloes. The milk is successively boiled, cooled, and mixed with a little curdled milk. The process is completed by churning the curdled mass, to which some hot water is once added. It is an article of commerce in India, but unpalatable to Europeans from its strong smell and flavor. It may be kept from rancidity by boiling till all the water is evaporated, and then adding curdled milk and salt, and preserving it in close jars.

GHEEL, a town and commune of Belgium, in the province and 26 m. S. E. of Antwerp; pop. 10,720. It has several churches and some manufactures. The commune has from time immemorial been a sort of asylum for insane persons, who are lodged and boarded in the houses of the peasantry.

GHEGA, **CARLO DE**, an Italian engineer, born in Venice in 1808, studied at Pavia, officiated as engineer in the construction of public works and railways in various parts of Italy and the Tyrol, visited the United States in 1842, and afterward wrote on the system of railways and bridges employed in the mountainous regions of the United States. As inspector in chief of the Austrian government railways, he superintended the railway through the Alps, and projected the celebrated passage over the Semmering.

GHENT (Flem. *Gend*; Fr. *Gand*; Ger. *Gent*), the capital of the Belgian province of East Flanders; pop. in 1857, 108,925. It is situated at the junction of the Scheldt and the Lys, 45½ m. by rail from Brussels, and intersected by a great number of navigable canals which communicate with those rivers, and form 26 islands connected with each other by about 80 bridges. The streets are spacious, and the fantastic variety of gable ends, rising stepwise or ornamented with scroll work and carving, imparts great picturesqueness to the stately houses. It has about 300 streets, 28 public squares, fine promenades, and a great number of churches. The sumptuous cathedral of St. Bavo contains the masterpieces of Jan and Hubert van Eyck. The city hall, with its Moorish front, the famous belfry, and the *Vrydagse markt*, or Friday square, where Jacques van Artevelde kindled the flames of civil war, and where the duke of Alva lighted the fires of the inquisition, are celebrated for their historical associations. The city is rich in charitable, industrial, artistic, literary, and scientific institutions, and possesses a university attended by about 300 students, with an extensive library and a botanical garden. There are 21 public hospitals, of which that called Bylogue can accommodate 600 persons. The *palais de justice*, the central prison, and the Béguinage, the principal establishment in Belgium of the Beguin nuns, are worthy of special mention. The cotton manufacture employs about \$9,000,000 of capital and upward of 20,000 persons, and produces annually 1,000,000 pieces of plain and printed calicoes. Sugar refining is also extensively carried on. The principal articles of trade are corn, oil, seeds, wine, and Flemish linens, of which about 20,000 pieces are exposed for sale every Friday.—Ghent is first mentioned as a town in the 7th century. It acquired importance during the middle ages, when the citizens established a form of municipal government, joined the association of the Hanse towns, and obtained the free navigation of the Rhine and other privileges. Toward the end of the 12th century it became the capital of Flanders, and by the end of the 13th it had so much increased in wealth and power that it was thought to eclipse Paris; and at a subsequent period Charles V. used sportively to say that he could put Paris into his *Gant* (glove). This emperor was born in Ghent, as was also John of Gaunt, "time-honored Lancaster," who derived from it his appellation. As early as the 14th century, the age of the Artevelde, Froissart estimated the number of fighting men whom Ghent could bring into the field at 80,000, no doubt an exaggeration. At the end of the 15th century there was, according to Erasmus, no town in all Christendom to be compared to it for size, power, political constitution, or the culture of its inhabitants. By its jurisdiction over many large but subordinate towns, Ghent controlled more than its own immediate population, which has been estimated as high as 200,000, although it possibly did not much exceed 150,000. The

constitution of the city was very liberal, and in all but theory it was a republic. All this prosperity was destroyed by the insurrection that broke out in the early part of the 16th century, which originated in the resistance of the citizens against onerous taxes. The emperor punished this resistance by depriving the city of all its privileges and immunities (April 29, 1540). The revenues belonging to it were confiscated; its ancient form of government was abolished; the right to appoint the city magistrates was vested in the crown; a new system of laws and political administration was established, and orders were given for erecting a strong citadel in order to bridle the revolutionary spirit of the population. A large fine for defraying its expenses was imposed upon the unfortunate citizens, as well as an annual contribution for the support of the garrison. At the same time 26 of the principal citizens were put to death, and a greater number sent into banishment. A congress assembled in Ghent in 1576 to form a confederacy for the expulsion of the Spaniards from the Netherlands. The massacre of Antwerp and the eloquence of the prince of Orange produced a quickening effect upon its deliberations, which had proceeded with decorum while the citadel was being cannonaded. The latter fell on the same day (Nov. 8, 1576) which saw the conclusion of the treaty known under the name of "Pacification of Ghent." But in the stormy period which followed, and in which the revolt against the Spanish authority was varied by intestine dissensions, the city became a prey to riot and anarchy. Early in the spring of 1584 a formal resolution was passed by the government of Ghent to open negotiations with Spain, and within 8 months after the murder of William of Orange, whose policy and self-sacrifice had saved the city on many occasions, it fell into the hands of the duke of Parma, the Spanish viceroy (Sept. 17, 1584). The citadel was rebuilt, and about a third of the population left the city. Before the expiration of the century, however (1596), Ghent, along with the other cities and provinces of the Netherlands, was severed from the crown of Spain in favor of Isabella, daughter of Philip II., who married Albert, son of the emperor of Germany. Louis XIV. took it in 1678, but soon after restored it to Spain in the peace of Nimeguen. During the war of Spanish succession, at the end of which it was given by the treaty of Rastadt to Austria, Ghent was alternately in the hands of both contending parties. It was also taken by the French in the war of the Austrian succession, and twice in the campaigns of the revolution, when it became the capital of the French department of the Scheldt. After the downfall of Napoleon in 1814 it was attached to the kingdom of the Netherlands. During the Hundred Days Louis XVIII. took refuge in Ghent. The famous *Moniteur de Gand* was issued there under the editorship of Baron Eekstein and M. Guizot and other friends of the Bourbons who gathered round Louis XVIII. The revolution

of 1880 made Ghent, with Flanders, a part of the new kingdom of Belgium.—Ghent is associated with American history by the treaty concluded there, Dec. 24, 1814, which terminated the war between Great Britain and the United States. The British commissioners for negotiating it, Lord Gambier, Messrs. Henry Gouldburn and William Adams, arrived in Ghent in Aug. 1814, where they found the American commissioners, Messrs. Adams, Gallatin, Bayard, Clay, and Russell, already assembled. The treaty, as signed, provided for the mutual restoration of all conquered territory, and for the mutual appointment of commissioners to examine and report to their respective governments on certain disputed boundary questions. Hostilities on land were to terminate with the ratification of the treaty, and on the ocean in certain specified periods, according to distance, of which the longest was 4 months.

GHERARDI DEL TESTA, TOMMASO, count, an Italian dramatist, born near Pisa in 1818, was graduated in 1826 as a doctor in law at the university of Pisa, and began to practise his profession in 1831. Subsequently he devoted himself to literature; and his first comedy, *Una folla ambiziosa*, was favorably received in Florence in 1845. He has since produced over 40 plays, the most celebrated of which are *Le scimmie* and *Le due sorelle*. Among his most recent plays is *Gustavo III.*, performed in Turin in the latter part of 1855. He has also written poems, the best of which is *Il Creatore ed il suo mondo*. He fought for the liberty of his country in 1848, fell into the hands of the Austrians (May 24), and was held in prison in Bohemia until the capitulation of Milan (Aug. 6).

GHERIAH, or **VIZIADROOG**, a town and fort of the Bombay presidency, British India, in the collectorate of Rutnagherry, S. Concan, 170 m. S. of Bombay. It has a safe harbor at the mouth of the river Kunvee, unobstructed by a bar and with a depth of 8 or 4 fathoms. The fort, built by the Mahratta chief Sevajee in 1622, stands on a bold promontory on the coast of the Indian ocean. It received the name of Gheriah from the Mohammedans, while by the Mahrattas it was commonly known as Viziadroog. During the maritime contests of the latter people with the Mogul emperors in the 17th century, one of their chieftains named Conajee Angria, who from a low station had risen to be admiral of the fleet and governor of the fortress of Severndroog, revolted against the Mahrattas with part of the fleet, and made himself master of the coast from Tanna to Rajapoor. Under this adventurer and his successors, who all bore the family name of Angria, Gheriah became the centre of a vast system of piracy, which swept the adjacent seas for upward of 50 years. Several attempts were made to disperse the corsairs. The Portuguese and English attacked them in 1722; the Dutch made a fruitless demonstration against Gheriah in 1724. In March, 1755, a British fleet under Commodore James, followed by

some Mahratta vessels, attacked Angria's fleet at Severndroog. The pirates escaped by fast sailing, but the town was bombarded and partly burned, the Mahrattas, who were only anxious for plunder, keeping beyond cannon shot till all was over. Toward the end of the same year reinforcements arrived from England, and the reduction of Gheriah was at once determined upon. On Feb. 11, 1756, Admiral Watson with 8 ships, a grab, and 5 bomb ketches, having on board 800 Europeans and 1,000 sepoys commanded by Col. Olive, arrived off the promontory, while a Mahratta army approached on the land side. The pirate fleet was soon burned; a furious bombardment silenced the guns from the fort; the troops were landed, and on the 18th, after a feeble resistance, the place was taken. It was given up to the peishwa under a treaty concluded with the Mahrattas the same year, and passed into the hands of the East India company in 1818.

Ghibellines. See **GUELPHS** AND **Ghibellines**.

GHIRBERTI, **LORENZO**, an Italian sculptor and painter, born in Florence in 1378, died there about 1455. The son of a goldsmith, he early learned to imitate ancient medals, and began to exercise himself in painting. The seignory and merchants of Florence determined in 1401 to procure for the baptistery of San Giovanni a bronze folding door to correspond with that already made by Andrea Pisano. A competition was opened, and 7 illustrious sculptors, of whom Ghiberti was one, contended for the prize, each of them to execute as a specimen of his talent a base-relief of the "Sacrifice of Isaac." Ghiberti was proclaimed victor, even by his most eminent rivals, Donatello and Brunelleschi. Intrusted, therefore, with this immense labor, he devoted 21 years to its accomplishment, dividing each half of the door into 10 panels, each of which contains a base-relief representing a subject taken from the New Testament. In 1424 this door was placed in one of the side entrances of the baptistery, and its success led to his being commissioned to execute another. This was commenced in 1428, was divided into 10 panels filled with subjects from the Old Testament, occupied him nearly as long as the other, and was superior to it, being declared by Michel Angelo worthy to be the gate of paradise. During the 40 years that he was engaged upon these doors he executed other works in bronze, among which was a statue of Saint John the Baptist, 2 base-reliefs for the cathedral of Sienna, a "Saint Matthew" and "Saint Stephen," and the reliquary of Saint Zanolius surmounted by 6 angels. The last, with the "Saint Matthew," and the second door of San Giovanni, are the masterpieces of modelling in the 15th century, and the door is perhaps still unrivalled. As an architect, Ghiberti was associated with Brunelleschi in constructing the cupola of Santa Maria del Fiore. He excelled in painting upon glass, and in the goldsmith's art. He also left a treatise

on sculpture, a part of which has been published by Cicognara; a treatise on proportions, yet unpublished; and a treatise on Italian art, first published in 1841.

GHKA, HELENA, princess, a Wallachian authoress, better known under the *nom de plume* of Dora d'Istria, born in Bucharest, Jan. 22, 1829. She received a brilliant education, travelled extensively in Europe, translated the *Iliad* into German at the age of 15, and married the Russian prince Koltzoff-Massalski, whom she accompanied to the court of St. Petersburg. She has written largely for a liberal Turin journal, *Il diritto*, and for an Athenian journal, *Le spectateur d'Orient*. Her principal works are: *La vie monastique dans l'église orientale* (Paris and Geneva, 1855; 2d and enlarged ed., Paris, 1858); *La Suisse Allemande et l'ascension du Mont* (4 vols., 1856; translated, 2 vols., Lond., 1858); *La nationalité Roumaine* (*Revue des deux mondes*, 1858 and 1859). Her latest work is *La Suisse Italienne*. She has also published in Italian *Gli eroi della Rumania* and *I Rumeni ed il papato*.

GHILAN, or JEKLAN, a province of Persia, bounded N. by Russia, N. E. by the Caspian sea, E. by the province of Mazanderan, S. by Irak-Ajemi, and W. by Azerbaijan; pop. estimated at about 300,000 prior to the plague in 1881, by which more than half the inhabitants are said to have perished. It is 170 m. in length, and 50 m. in breadth. The country near the Caspian is for the most part level and swampy, but the interior has lofty mountains crowned with magnificent forests. The climate is moist and unhealthy. The principal productions are silk, rice, and corn. The annual value of silk produce is about \$3,000,000; the fisheries of sturgeon and other fish are extensive, the former in the hands of the Russians. There are few towns, the inhabitants mostly dwelling in single houses, or small hamlets. Capital, Reshad.

GHIRLANDAIO (otherwise called CORRADI, or BICHONDI, DOMENICO DEL, an Italian painter, the master of Michel Angelo, born in Florence in 1451, died there in 1495. His father was a goldsmith, called Ghirlandaio from the silver ornaments in the shape of garlands which he manufactured; and the son, who was brought up to the same calling, inherited the name. Domenico early manifested an extraordinary aptitude for portraiture, and after studying under Alessio Baldovinetti, went to Rome to assist in the decoration of the Sistine chapel. Of the pictures executed by him there but one now exists, the "Calling of St. Peter and St. Andrew." Upon returning to Florence he painted a chapel of the Vespucci family in the church of Ognissanti, in one of the compartments of which he introduced a portrait of the navigator, Amerigo Vespucci. Of greater excellence was his series of frescoes in the Sassetti chapel in S. Trinita representing the life of St. Francis. The picture of the death of the saint is particularly impressive. In these works, as in the frescoes in the choir of Sta. Maria Novella

depicting the lives of John the Baptist and the Virgin, he gratified his love of portrait painting by introducing likenesses of many eminent Florentines of the period; "the portrait," according to Kugler, "in the largest signification of the word, being the prominent characteristic in his productions." He painted many easel pictures in oil and distemper; but his frescoes, in the coloring of which, as well as in the mechanical and technical parts of his art, he excelled all previous painters, are incomparably his finest works. He is said to have created aerial perspective, and to have perfected the art of mosaic. Two brothers and a son of Ghirlandaio were also painters of some distinction.

GHIZEH, GIZKE, GHEZEK, GEEZEK, or JIZEH, a town of Egypt, capital of a province of the same name, on the W. bank of the Nile, 8 m. S. W. of Cairo. It was once a great and handsome city, but is now a petty village surrounded by heaps of ruins. About 5 m. from the village stand the 3 great pyramids called those of Cheops, Cephren, and Mycerinus. At Ghizeh are egg-ovens, in which eggs have been hatched by artificial means ever since the days of the Pharaohs. (See PYRAMIDS.)

GHUZNEE, or GHIZNEE, also GHAZNA, a fortified city of Afghanistan, on the river Ghuznee, 80 m. S. W. of Cabool; pop. estimated at from 3,000 to 10,000. It is a commercial entrepot between the Punjab and Cabool. In ancient times it was a magnificent city, filled with palaces, mosques, fountains, reservoirs, and baths. Two lofty minarets, the smaller of which is more than 100 feet high, several tombs, and a quantity of ruins scattered over a wide area 3 m. N. E. of the modern town, are the only relics of its former grandeur. In 976 Abustakeen, governor of Khorasan under the king of Bokhara, revolted against his sultan and established at Ghuznee the seat of an independent empire, including Cabool and Candahar. It was under Mahmoud, the 8d prince of this new dynasty, that Ghuznee acquired historical importance as the centre of the first permanent Mussulman conquests in India. Mahmoud extended his victories from the Tigris to the Ganges, from the Indian ocean to the Oxus. He made no fewer than 12 great military expeditions, breaking idols, plundering temples, and rendering his capital one of the richest cities of Asia. He built a mosque of granite and marble, and lavished upon it ornaments of such magnificence that throughout the East it was known as the "celestial bride." He founded and endowed a university; he patronized literature, and filled his court with poets and philosophers. After his death Ghuznee declined. In 1152 it was taken by the prince of Ghore. In 1889 it was stormed by the British under Sir J. Keane. In 1842 it surrendered to the Afghans, but was retaken by Gen. Sir William Nott, who brought back to India the famous gates of Somnauth, which Mahmoud carried off from Guzerat.

GIANNONE, PIETRO, an Italian historian, born in Ischitella, March 7, 1676, died in Turin,

March 7, 1748. He conceived the idea of writing the history of Naples while listening to the distinguished Neapolitans who frequented the house of the juriconsult, Argento. This work was completed in 1723, and treats not only of political events, but also of laws and manners. It was received with great favor by the public, and procured him an office and a pension; but its attacks upon the temporal power of the papacy and its censures of the court of Rome drew upon him the hostility of ecclesiastics. Excommunicated and banished, he retired to Vienna, and thence successively to several of the cities in N. Italy, and lived for a time in Geneva. Being treacherously invited to Turin, he was arrested in 1736, by order of the king of Sardinia, and passed the remainder of his life in prison. His posthumous works were first published at Geneva in 1760.

GIANT (Gr. γίγας, probably from γη and γαω, earth-born), a person of extraordinary size. In Greek mythology, a race of giants dwelt, according to Homer, in the distant west, and were destroyed by the gods for their presumption. Hesiod considered giants divine beings, who sprang from the blood of Uranus as it fell on the earth; and by later poets they were represented as enemies of Jupiter, and as vainly attempting to take Olympus by storm. They were usually placed in volcanic districts, and the legends of their contests with the gods may have originated from volcanic convulsions. The wars waged by the giants and by the Titans, though originally distinct, are often confounded.—In Scandinavian mythology the giants or jotuna are scarcely distinguished from the trolls, though originally the trolls were supposed to be more systematically malignant than the giants, who were rather dull than wicked. They all dwelt in wild pine forests, in caves and clefts of rock, amid heaps of gold and silver and all the treasures of the mineral world. They strode through the dark forest by day, whither no rays of the sun could penetrate, and returned at nightfall to feast and sleep. The sight of the sun was fatal to them, and if they once saw it they burst or were transformed to stone. It is probable that the giants living amid the woods and rocks may be a reminiscence of the gradual suppression and extinction of some hostile race, who, retiring into the natural fastnesses of the land, wandered from forest to forest and from fell to fell, till at last they became mythical. A more ancient tradition was that of the frost giants, personifications of natural powers, who dwelt in Utgard beyond the sea which flowed round the earth in a ring, and who had been dispossessed by Odin and the Asen divinities. There was perpetual feud between the gods of Asgard and the giants of frost and snow, similar to that between the race of men and the trolls.—Giants abound in German legends, and figure with dwarfs, fairies, and magicians in the mediæval romances of chivalry. After the discovery of America stories of gigantic races in the new world were not uncommon,

and the Patagonians especially were said to be 8 and even 12 feet in stature. It is now known that most of the men are 6 feet in height. The women also are unusually tall. Buffon admits 15 authenticated cases of gigantic men. One of these is Hans Bar, 11 feet high, whose likeness, drawn in 1550 of full size, remained in the imperial castle at Innspruck. A Hungarian foot soldier of the archduke Ferdinand is mentioned, who attained the same stature, and his likeness remains in the Ambrosian cabinet at Vienna. Of later giants, one of the best known is Bernhard Gili, who was exhibited in France and Germany in 1764, and whose height, which was stated to be 10 feet, was certainly more than 8 feet. Another example of extraordinary stature was Patrick O'Brien (1761–1806), called the Irish giant, who attained the height of 8 feet 7 inches, and for many years exhibited himself in Great Britain, chiefly in London and at the Bartholomew fairs at Smithfield. His hand, from the commencement of the palm to the extremity of the middle finger, measured 13 inches, and his shoe was 17 inches long. Daniel Lambert (1770–1809) was only 5 feet 11 inches high, but so corpulent that at his death he weighed 789 lbs. Miles Darden of Tennessee (1798–1857) was 7 feet 6 inches high, and weighed at his death over 1,000 lbs. In the anatomical room of Trinity college, Dublin, is preserved the skeleton of a youth named Magrath, born near Cloyne in Ireland. He was 7 feet high in his 16th year, but soon after became imbecile, and died as if of old age in his 20th year. The inhabitants of Potsdam, many of whom are descended from the famous regiment of tall grenadiers formed by Frederic William I., are said to be still remarkable for their superior height.

GIANTS' CAUSEWAY, a series of basaltic rocks in the co. of Antrim, on the N. E. coast of Ireland. For the extent of 8 m., between the promontories of Bengore and Fairhead, the land abuts upon the sea in cliffs of basalt, many of which are made up in great part of rude vertical columns which alternate with layers of amorphous beds of the same class of rock. Ranges of these piled upon each other sometimes reach the height of 400 feet, or at Fairhead even 550 feet. As seen from the sea in front of them, the uniformity of the arrangement of vertical columns and horizontal beds suggests rude resemblances to architectural forms. At the base of the cliffs is a talus of ruins that have fallen from the structures above and slope down to the water. But though the name of Giants' Causeway is often applied to all this coast range, it is properly applicable to but a small portion of it—to a locality quite unpretending in its extent or in the grandeur of its features. It is a platform of basalt, composed of closely arranged columns, the greatest height of which is only about 20 feet. This platform extends from a steep cliff down into the sea, till it is lost below low water mark. Its length exposed at low water is differently given, but probably is less than 600 feet. It is

divided across its breadth into 3 portions, which are called the Little Causeway, the Middle, and the Large or Grand Causeway; the first being the first encountered in approaching from the sea. These are separated from each other by dikes of amorphous basalt. The Great Causeway, which is the principal object of interest, is only from 20 to 30 feet wide, though detached outliers of the same columnar structure standing up on the shore near by might be added to increase the width. They no doubt connect with the same group below the surface. The columns are for the most part hexagonal prisms; but they are found also of 5, 7, 8, and 9 sides, and in one instance at least of 8 sides. They are all jointed into short irregular lengths from a few inches to a few feet each, the articulations being perfectly fitted by a convex end entering the concavity of the adjoining piece, so that the blocks form a true column. There is no uniformity in the arrangement of the convexities and concavities, a block sometimes presenting one or the other, or one of each at each end. The diameter is variable, but ranges generally from 15 to 20 inches. The columns fit together with the utmost precision, the corresponding faces of adjacent prisms being always equal, and so continuing from the top of the platform till the lines of separation are lost beneath the ground. It is said that water even cannot penetrate between adjoining columns. The name causeway is given to the group from the circumstance of the columns terminating at a uniform height, and thus presenting a tolerably smooth area gently inclining to the water. This portion is about 100 yards in length, extending from high water mark to within 20 feet of the cliff. The other portions are more uneven, and the columns in them are not uniformly vertical, but slope outward along the sides. The columns of basalt do not retain their articulated character throughout the cliffs. At Fairhead they rise in single pieces, and, as measured by the officers of the ordnance trigonometrical survey of Ireland, some are found to stand 317 feet in height with sides occasionally of 5 feet in breadth. These are flat at their extremities. The formation is intersected by narrow dikes of columnar basalt, in which the prisms are piled horizontally, ranging across the line of the dikes. (For further facts relating to this formation, see BASALT.) In this region it appears to have been protruded after the period of the deposition of the lias and chalk, the strata of these formations being penetrated by its dikes and overlaid by its horizontal beds. The district affords an excellent opportunity for the study of the changes induced upon the sedimentary rocks by contact with those of igneous origin, of which Buckland and Conybeare availed themselves at an early period. Their observations, containing much new and instructive matter, were published in vol. iv. of the "Geological Transactions."

GIAOUR, a term of insult applied by the Turks to all unbelievers in Mohammedanism, and especially to Christians. The sultan Mah-

moud II. forbade his subjects to apply it to any European Christian. It is equivalent to the English words "heathen," "pagan," or "infidel."

GIBBES, ROBERT WILSON, an American physician and author, born in Charleston, S. C., July 8, 1809. He was graduated at South Carolina college, and having become a physician, removed from Charleston to Columbia, of which city he has twice been mayor. He is now president of the medical association of South Carolina. Among his numerous contributions to medical and scientific publications are articles on "Physio and Physicians" and the "Geology of South Carolina" in the "Southern Quarterly Review," monographs on fossil species in the "Journal of the Academy of Natural Science," and various zoological and palaeontological discussions in the collections of the Smithsonian institution and in the "Proceedings" of the American association for the advancement of science. In his paper on "Typhoid Pneumonia" in the "American Journal of Medical Sciences" (1842), he was the first to advocate the use of stimulants instead of the lancet in the treatment of that malady. He has prepared a "Documentary History of the American Revolution, consisting of Letters and Papers Relating to the Contest for Liberty, chiefly in South Carolina" (3 vols., Columbia and New York, 1853 *et seq.*).

GIBBON, EDWARD, an English historian, born in Putney, Surrey, April 27, 1737, died in London, Jan. 16, 1794. He was the eldest of 7 children, all the rest of whom died in their infancy, and he was so feeble in his youth that many times he seemed likely to share their fate. His aunt, Catharine Porten, took charge of him and watched over him with unceasing care. At the age of seven a domestic tutor, John Kirkby, taught him the elements of Latin. In his 9th year, during "a lucid interval of health," he was sent to the grammar school of Kingston-upon-Thames, where he remained 2 years. His mother having died in 1747, he removed with his father and aunt to Buriton, Hampshire, where he began to read voluminously. In Jan. 1749, Mrs. Porten opened a boarding house for Westminster scholars, and Gibbon enjoyed her care while he attended the school, but, owing to delicate health, learned little. In his 16th year his health improved, a sudden change took place in his constitution, and his mind seemed at the same period to have gained new activity. He now read assiduously, chiefly upon historical subjects; as yet he knew very little Latin or Greek, and preferred translations to the difficult originals. In 1753 he went to Oxford, and arrived "with a stock of erudition which might have puzzled a doctor, and a degree of ignorance of which a school boy might have been ashamed." Neglected by his tutor, he gave himself to general reading. He was then fond of oriental research, and bought the *Bibliothèque orientale* of D'Herbelot with his spare money. He began his history of the "Age of Sesostris," which he at first hoped to print, but finally burned. He was also busy with religious controversy, and having read

Bossuet's "Variations of Protestantism" and "Exposition of Catholic Doctrine," as well as other controversial writings, became a Roman Catholic, and resolved to proclaim his conversion openly. He went from Oxford to London, and there, before a Catholic priest, abjured Protestantism, and was reconciled to the church. Next he wrote a long controversial letter to his father, informing him of his conversion. The father revealed the secret, and Gibbon was expelled from Oxford, after a residence there of 14 months. He was now consigned to Switzerland in a kind of exile, and placed under the care of M. Pavillard, a Calvinistic minister at Lausanne, who it was hoped would reconvert him. He lived in a plain manner in M. Pavillard's house, and at first lamented the loss of English luxury. But soon his passion for study revived; he read systematically the Latin, Greek, and French classics, Crousz, Locke, and Grotius, and was especially delighted with the "Provincial Letters" of Pascal, from which he learned "to manage the weapon of grave and temperate irony, even on subjects of ecclesiastical solemnity." During the 5 years of his exile he made the French language more familiar to him than the English. He returned to Protestantism on Christmas, 1754, 18 months after his conversion to Catholicism, and from that time he cared little for theological distinctions. At Lausanne he formed an attachment for an accomplished Swiss young lady, Mlle. Susanne Curchod. His father, however, disapproved of the connection, and Gibbon philosophically resigned the object of his love, who afterward became the wife of the banker Necker. "I sighed," he says, "as a lover, but obeyed as a son." It is not a little remarkable that they remained ever after friends. In the summer of 1758 his father permitted him to return to England. He was received by his stepmother with a kindness which he was glad to return, and passed 2 years chiefly in study at the family seat, Buriton, and accomplished a course of classical reading equalled by few of his contemporaries. On a visit of several months to London he passed most of his time as a literary recluse, but became intimate with David Mallet, by whose counsel he made an assiduous study of the most esteemed English authors, as Addison, Swift, Robertson, and Hume. He next joined with his father the Hampshire militia, and for 2½ years studied practically the military art. Even in the camp he found time for books, and meditated a number of great literary projects, among which was a history of the crusade of Richard Cœur de Lion, of the wars of the barons, of the expedition of Charles VIII. into Italy, and lives of Edward the Black Prince, Sir Philip Sidney, and Sir Walter Raleigh. In 1761 he published a brief work, his *Essai sur l'étude de la littérature*, which he had commenced at Lausanne, designed to defend classical studies against the attacks of the French philosophers. The essay was written in French, and was commended by foreign critics, though scarcely no-

ticed in England. He travelled in 1763, and on his way to Lausanne spent 8 months at Paris. His essay had given him some renown, and he frequently met D'Alembert, Diderot, Baron d'Holbach, and the other philosophers, with whose society he was so much pleased that he says: "Had I been rich and independent I should have prolonged, and perhaps have fixed my abode at Paris." After remaining at Lausanne nearly a year, he passed in 1764 into Italy. As he approached Rome, he occupied his mind with its antiquities and topography. He read Nardini, Donati, Cluverius; he filled his commonplace books with copious extracts, and stored his memory with abundant learning before he ventured to cross the forum or ascend the Capitoline hill. With emotions almost uncontrollable he entered the sacred city, and a sleepless night preceded his first walks to survey its relics of classical antiquity. In them he found a theme worthy of his literary ambition and historic genius. "It was at Rome," he writes, "on the 15th of Oct. 1764, as I sat musing amid the ruins of the capitol, while barefooted friars were singing vespers in the temple of Jupiter, that the idea of writing the decline and fall of the city first started to my mind. But my original plan was circumscribed to the decay of the city, rather than of the empire; and though my reading and reflections began to point toward that object, some years elapsed, and several avocations intervened, before I was seriously engaged in the execution of that laborious task." He went south to Naples, returned to Paris, and reached his father's house in June, 1765. At Lausanne in his earlier visits he had formed an intimacy with M. Deyverdun, a young Swiss of fine scholarship, who now visited him yearly at Buriton. With his aid Gibbon began writing a history of the liberty of the Swiss. After two years of study and preparation, he submitted the first book, which was written in French, to a literary club of foreigners in London, by whom it was at once condemned, and the work went no further. He next, in connection with Deyverdun, started the *Mémoires littéraires de la Grande Bretagne*. It was designed to be annual, but 2 volumes only were printed (1767-'8), when Deyverdun went abroad. His next work was an anonymous and acrimonious attack on that portion of Warburton's "Divine Legation of Moses," in which he supposes the 6th book of the *Æneid* to contain an allegorical account of the initiation of *Æneas* in the character of a lawgiver into the Eleusinian mysteries. Though Warburton was the ruling critic of the time, Gibbon's "Critical Observations" (1770) were admitted to have overthrown his hypothesis. The subject was one that could have little general interest, but the unknown author was mentioned by Heyne of Göttingen as a *doctus et elegantissimus Britannus*. His father having died in Nov. 1770, Gibbon settled in London, and with a considerable, though somewhat embarrassed estate, lived in studious ease, and began to

labor more directly upon his "Decline and Fall," which he had been wont to "contemplate at awful distance." His library was extensive, and had been selected with care; his materials were around him, and he wrote with method. With pen in hand he plunged into "the ocean of the Augustan history," pored over all the remains, Greek and Latin, between Trajan and the last of the western Cæsars, studied medals and inscriptions, the Theodosian code, the Christian apologists, the collections of Tillemont, the annals and antiquities of Muratori, and brooded long over his chaos of materials before he was able to determine the limits, divisions, or even the title of his work. He practised on his style, cultivated his ear for harmony, and finally by labor acquired his elevated and sonorous mannerism. The 1st chapter of the history he rewrote 8 times before he was satisfied with it, and the 2d and 3d chapters twice, after which he proceeded with facility. In 1774 he entered the house of commons as member for the borough of Liskeard, in which he sat for 8 years a silent supporter of the measures of Lord North. Such was his timidity that he was never able to address the house; more than once he prepared himself to speak, but when the moment for action came his courage wholly deserted him. Near the close of 1775 the first volume of his history was completed. It was refused by the bookseller Elmsly, but accepted by Cadell and Strahan. It appeared in Feb. 1776; its success was immediate, and, for a quarto and grave historical production, unprecedented. The 1st edition was exhausted in a few days; a 2d and 3d were soon called for. Hume and Robertson, to whom he sent copies, wrote him congratulatory letters. His splendid theme and imposing style fired the attention of the public, while his malevolent views of Christianity in the last two chapters called forth a host of replies. Watson, Taylor, Milner, Lord Hales, Davies of Oxford, and Dr. Priestley were the most noted of his assailants; but to Mr. Davies alone would the historian consent to reply, because this critic had questioned not his faith, but his historical fidelity. His "Vindication" soon appeared, in which he freed himself from the charge of misquotation. Meantime he studied chemistry and anatomy for recreation. He wrote a political pamphlet in French, in defence of the ministry, and was rewarded with a sinecure place in the board of trade worth £800 a year. He was a member of the literary club, and a noted conversationalist. The 2d and 3d volumes of his history were published in 1781, and were received with avidity, though less clamorously than the 1st. On the fall of Lord North's ministry and the loss of his salary by the abolition of the board of trade, Gibbon thought himself too poor to live in England, and determined to fix his abode at Lausanne, whither he repaired in 1783 to reside with his friend Deyverdun. His 4th volume, embracing the reign of Justinian and the chapter on the Institutes, was already finished, but on the borders of the lake of Geneva he allowed

nearly a year to pass before he vigorously resumed his work. He was fond of society, and became highly popular among the Swiss; he gave balls and suppers, frequented assemblies, and even after he was fairly sequestered at his task mingled gayety with constant study. Eminent visitors, as Prince Henry of Prussia, M. and Mme. Necker, Mr. Fox, and the duchess of Devonshire, discovered and enlivened his Swiss retreat. He wrote steadily and rapidly till he completed his work. "It was on the day, or rather night, of the 27th of June, 1787, between the hours of 11 and 12, that I wrote the last lines of the last page in a summer house in my garden. . . . The air was temperate, the sky was serene, the silver orb of the moon was reflected from the waters, and all nature was silent. I will not dissemble the first emotions of joy on the recovery of my freedom, and perhaps the establishment of my fame. But my pride was soon humbled, and a sober melancholy was spread over my mind by the idea that I had taken an everlasting leave of an old and agreeable companion; and that whatsoever might be the future date of my history, the life of the historian must be short and precarious." He went over to England bearing the manuscript of the last 3 volumes with him, and on his 51st birthday, the period selected by himself, they were issued. The work was already established in fame; it was translated into German, French, and Italian. His profit from all the volumes is stated to have been £6,000, and that of the booksellers £80,000; but on this subject nothing is known. The latter volumes were reproached for indecencies, veiled for the most part in the learned languages in the notes. Gibbon returned to Lausanne in July, 1788, to find his friend Deyverdun dying. He hired the house which they had occupied together, and invited the family of the Severys to live with him, consisting of a father, mother, son, and daughter. They presided over his house and amused his leisure. At this time he wrote his own "Memoirs," which were published posthumously. The French revolution disturbed his repose. Lausanne was filled with French emigrants; the Neckers with their daughter, afterward Mme. De Staël, were his neighbors at Coppet. Lady Sheffield, the wife of his intimate friend Lord Sheffield, died about this time, and Gibbon, partly in the hope of consoling his friend, partly in fear of the revolution, set out for England in the spring of 1798. He had long suffered from hydrocele, which he had studiously concealed, and he died calmly after undergoing 8 painful operations in vain. He was buried in Lord Sheffield's family burial place at Fletching, in Sussex, and his epitaph was written by Dr. Parr.—In appearance Gibbon was heavy and dull, his countenance showed no trace of intellect, and his features were unattractive. He was fond of fine dress, and his manners were well bred but pompous. He conversed with fluency in sounding language and well ordered periods. Few generous or elevated acts are told of him. His

"Decline and Fall of the Roman Empire" is admitted to be the greatest historical work in the English language, and one of the greatest creations of any single intellect. It is hardly less than the history of the world for nearly 18 centuries, for it comprises an account of all the nations who influenced the destinies of the Roman empire both in the West and East. Its vast design, including the decay and ruin of an ancient civilization and the birth and formation of a new order of things; its lucid arrangement, subordinating an infinite variety of subjects to one main and predominant idea, tracing the progress of hostile religions, the influx of successive hosts of barbarians from remote and opposite quarters, the development of the Roman law, the details of ecclesiastical history, and the gradual rise of modern states, according to the impressions which they made on the tottering fabric of Roman greatness; its singular condensation of matter, general accuracy, and monotonously splendid, imposing, and picturesque style, are among the qualities which secure its eminence in historical literature. "Christianity alone," says Milman, "receives no embellishment from the magic of Gibbon's language; his imagination is dead to its moral dignity; it is kept down by a general tone of jealous disparagement, or neutralized by a painfully elaborate exposition of its darker and degenerate periods."—The best editions are those edited by the Rev. H. H. Milman, with notes, (12 vols., London, 1838-'9; 2d ed., 6 vols., 1846; New York and Boston, 1856), and by an English churchman, with variorum notes, in Bohn's "British Classics" (7 vols., London, 1858-'5); also, best of all, that in Murray's "British Classics," with additional notes by Dr. William Smith (8 vols., London, 1854-'5). Gibbon's memoirs and miscellaneous writings were published under the care of Lord Sheffield (2 vols., London, 1796, to which a 3d volume was added in 1815).

GIBBS, GEORGE, an American mineralogist, born in Newport, R. I., Jan. 8, 1782, died in Newtown, N. Y., Aug. 5, 1838. Early becoming interested in the study of mineralogy, he collected during his travels in Europe, chiefly by purchase, a very extensive and valuable cabinet of minerals, in some respects the richest ever brought together in the United States. This collection he brought home in 1807, and set it up in the public rooms of Yale college, where it remained without charge from 1811 to 1825. In the latter year it was purchased for the college for \$20,000.

GIBBS, JOSEPH WILLARD, an American philologist, born in Salem, Mass., April 30, 1790, was graduated at Yale college in 1809, and was tutor in that institution from 1811 to 1815. In 1824 he was appointed professor of sacred literature in the theological department of Yale college, and he still continues in this station. In 1853 the degree of LL.D. was conferred on him by the college of New Jersey. In his special department, and in philological and gram-

matical studies generally, he is well known as a scholar of uncommon thoroughness and accuracy. His principal publications are, a translation of Storr's "Essay on the Historical Sense of the New Testament" (12mo., Boston, 1817); translation of Gesenius's "Hebrew Lexicon of the Old Testament" (8vo., Andover, 1824); "Manual Hebrew and English Lexicon," abridged from Gesenius (8vo., Andover, 1828; 2d ed., New Haven, 1832); "Philological Studies" (12mo., New Haven, 1837); "Latin Analyst" (New Haven, 1858). He is the author of several sections of Prof. W. O. Fowler's work on the English language, and has contributed to the periodical works of his time numerous important papers on topics of philology and criticism.

GIBEON, one of the principal cities of Palestine, about 5 m. N. W. from Jerusalem. Before the conquest of Canaan by Joshua, it was inhabited by Hivites, who by stratagem secured their own safety and protection from Israel; though when the deception was discovered the Gibeonites were degraded to the condition of hereditary "hewers of wood and drawers of water unto all the congregation." It is not mentioned as one of the royal cities of the Canaanites, though described as "a great city, and as one of the royal cities." When the 5 kings of the Amorites besieged Gibeon because of its having made peace with Israel, Joshua marched against them, and at his command "the sun stood still, and the moon stayed, until the people had avenged themselves upon their enemies" (Josh. x. 1-14). The Gibeonites were persecuted and nearly exterminated by Saul. On the division of Canaan, Gibeon fell to the tribe of Benjamin; afterward it was given to the Levites; toward the close of David's and in the beginning of Solomon's reign, the sanctuary was there, and there dwelt the high priest. Near to it was a pool, probably the "great waters" referred to by Jeremiah, where Abner was defeated by Joab, and also a great stone, or monumental pillar. It is identified with the modern El Jib, an irregular village, seated on the summit of a hill, and containing massive ruins.

GIBRALTAR (anc. *Mons Calpe*), a fortified promontory of Andalusia, Spain, belonging to Great Britain, and giving name to a town and bay on its W. side, and to the strait connecting the Atlantic and Mediterranean; lat. of Europa point, its S. extremity, 36° 2' 30" N., long. 5° 15' 12" W. This promontory and Ceuta (anc. *Mons Abyla*), on the opposite coast of Africa, constitute the ancient pillars of Hercules, long regarded as the western boundary of the world. It consists of rock, principally a gray compact marble, 8 m. long from N. to S. and but 7 m. in circumference, about 1,600 feet above the level of the sea at its highest point, and connected with the mainland by a narrow sandy isthmus, called the neutral ground, about 1½ m. long. The N., E., and S. sides are so steep and precipitous as to be almost wholly inaccessible; the W. side, toward the bay, slopes down to

the water, and here are situated the town and the principal fortifications. The rock is perforated by a number of remarkable caverns, in which many bones of animals and of men have been found. There is little soil, but acacia, fig, and orange trees, and a variety of plants, grow in some sheltered glens. Among the few native animals are the only wild monkeys found in Europe, a peculiar tailless species, which are protected from destruction by public sentiment, being regarded as almost sacred. Immense sums have been expended upon the fortification of this rock, which nature and art combined would appear to have rendered literally impregnable. The most remarkable works are the galleries—two passages cut through the solid rock, between 2 and 8 m. long, wide enough to admit a carriage, and pierced with port holes at every 12 yards in such a manner as to command the bay and the neutral ground. About 1,000 guns altogether are mounted upon the rock. In 711 a body of Moors took possession of this promontory, and named it from their leader Gebel el Tarik (Tarik's mountain), whence the present name. Of the fortifications erected by them, a tower still remains. They held it till 1809, and again from 1833 to 1463, when they were finally expelled by the Spaniards. The latter greatly strengthened it, and regarded it as impregnable; but it was taken by a combined English and Dutch fleet in 1704, and was confirmed to Great Britain by the treaty of Utrecht in 1718. In Feb. 1727, the Spaniards attacked it with a large force, but raised the siege on the signing of preliminaries of a peace with Great Britain in May of the same year. In 1779 the attempt was renewed with the aid of a French squadron. By June 21 all communication between the rock and the mainland was cut off, and in July the fortress was completely blockaded. The cannonading began in September on the part of the besieged, but the Spaniards did not open their fire until Jan. 1780. The attack and defence which now followed fixed the attention of the whole of Europe for the next 3 years. On the part of the besiegers all the resources of war were brought to bear both by land and sea. The best engineers of France and Spain directed the approaches; a powerful fleet anchored in the bay, and for 3 weeks an incessant bombardment was kept up from 80 mortars and 200 pieces of battering cannon. The garrison, commanded by Gen. Eliott (afterward Lord Heathfield), and numbering 7,000 men, made a heroic resistance. On Nov. 27, 1781, they destroyed the enemies' works in a sortie, but the allies at once reconstructed them, and soon brought 1,000 pieces of artillery to play against the fortress, while 47 ships of the line and innumerable smaller vessels menaced it by sea, and an army of 40,000 men conducted the operations on land. The whole enterprise was directed by the duke de Crillon. Meanwhile Admiral Rodney, having defeated the fleet of Count de Grasse, succeeded in throwing relief

into the fort, and the British were still further encouraged by the effect of the red-hot shot which they discharged against the batteries and shipping. In Sept. 1782, the allies attempted to silence the British fire by means of 10 enormous floating batteries constructed under the chevalier d'Arcon in such a manner as to be deemed invulnerable. Each was manned by a picked crew and mounted from 10 to 18 guns. On the 18th they were put in motion, and at about 10 in the morning one of the most dreadful cannonadings known in history was opened on both sides. It continued for several hours with little advantage to either party, but late in the afternoon the effect of the red-hot shot from the garrison became apparent, and soon after midnight 9 of the batteries were on fire. Of their crews about 400 men were saved by the exertions of the British; the rest perished by the flames, explosions, or drowning. The besieged had 16 killed and 68 wounded. Several attempts to storm the rock by land proved equally disastrous; the British received fresh reinforcements, and in Feb. 1783, the siege was raised on the announcement of the general peace. —The town of Gibraltar is built near the foot of the N. W. side of the hill, with paved and lighted streets and houses in the English style; pop. in 1854, 15,823. Its principal edifices are the residences of the governor and lieutenant-governor, the admiralty, barracks, storehouses, cathedral, Spanish church, synagogue, naval hospital, lunatic asylum, and almshouses. It contains a public library with 15,000 volumes, a medical library, and one founded by the merchants. Great pains are taken to prevent the increase of new residents, and foreigners are allowed to remain only during specified periods and on giving security for good behavior. The trade has declined since the commencement of the 19th century. The exports to Great Britain comprise wool, tobacco, wine, silk, and senna, and the imports consist chiefly of wine, spirits, tobacco, spices, tea, and cotton. Vessels entered in 1854, 3,678, tonnage 589,560; vessels cleared, 3,598, tonnage 581,463. The revenue in 1855 amounted to £30,899, and the expenditures to £29,830. —The bay of Gibraltar, or Algeciras bay, lying between Cabarita and Europa points, is 5 m. in greatest width from E. to W. and 8 m. long, deep, convenient, and well sheltered. It has 2 moles respectively 700 and 1,100 feet long. —The strait, anciently called the straits of Hercules, or of Gades (*Fretum Gaditanum*), extends about 86 m. nearly E. and W., its width at the E. extremity, between Europa point in Spain and Ceuta point in Africa, being about 15 m., and at the W., between Capes Trafalgar on the Spanish and Spartel on the African coast, 24 m. Its narrowest point is about the middle, where the opposite coasts are but 9 m. apart. There is a constant current through this channel from the Atlantic into the Mediterranean, and two counter-currents, of inferior breadth and rapidity, flow westward, one along each coast.

GIBSON. L. A. W. co. of Tenn.; area, 520 sq.

m.; pop. in 1850, 19,548, of whom 4,194 were slaves. The surface is generally even and the soil fertile. The productions in 1850 were 1,107,780 bushels of Indian corn, 93,734 of oats, 4,918 bales of cotton, and 466,390 lbs. of tobacco. There were 17 corn and flour mills, 10 saw mills, 5 tanneries, 1 newspaper office, 43 churches, and 1,150 pupils attending public schools. The Mobile and Ohio railroad, and the projected route of the Memphis and Ohio railroad, pass through the county. Capital, Trenton. IL A S. W. co. of Ind., bordering on Illinois; area, 449 sq. m.; pop. in 1850, 10,771. It has an undulating surface and a rich soil, watered by the Wabash and Patoka rivers, the former of which forms the W. boundary of the county. The productions in 1850 were 947,590 bushels of Indian corn, 43,888 of wheat, 77,686 of oats, and 1,693 tons of hay. There were 15 corn and flour mills, 4 saw mills, 8 tanneries, 2 newspaper offices, 19 churches, and 2,060 pupils attending public schools. Live stock and coal are among the most valuable exports. The Wabash and Erie canal and the Evansville and Crawfordsville railroad intersect the county. Capital, Princeton.

GIBSON, JOHN, an English sculptor, born at Conway, North Wales, in 1791. His father soon after removed to Liverpool, and young Gibson, after endeavoring to prevail on his parents to allow him to study painting, for which he had shown a predilection, was articulated at the age of 14 as a cabinet maker, and soon after to a wood carver. In this employment he remained until a visit to the marble yard of the Messrs. Francis filled him with the desire of becoming a sculptor. These gentlemen, upon hearing of the circumstance, purchased his indentures and took him into their employment. As his talent began to develop itself he attracted the notice, among others, of William Roscoe, who invited him to his house, lent him prints and models, and encouraged him to pursue the career of a sculptor. A fund was soon raised in Liverpool to enable him to prosecute his studies in Italy, and in 1817 he departed for Rome, where he has since resided. Lord Brougham and others had given him letters to Canova, and that eminent sculptor, after examining Gibson's sketches, not only received him into his studio, but offered him pecuniary assistance, and recommended him to some of the wealthiest patrons of art. On the death of Canova he placed himself under Thorwaldsen, thus enjoying within the space of a few years the society and tuition of the two most famous sculptors of the century, whose distinctive qualities he has very happily united in his own works. It was not until 1827 that Gibson sent his first contribution to the exhibition of the royal academy, "Psyche borne by the Zephyrs," executed for Sir George Beaumont. Several other works followed, and in 1836 he was elected a full member of the academy, having for some years previous been an associate. The works which have left Gibson's studio

during his long career are principally portrait statues, and ideal pieces founded on classic models. Of the former, the best known are his statues of Queen Victoria in Buckingham palace, Osborne, and the new palace at Westminster, the 3 of Huskisson in Liverpool, and those of Sir Robert Peel and George Stephenson. They are all works of an impressive character, and would be nearly perfect if the artist had not adhered to the now nearly obsolete practice of habiting his figures in classic costume, whereby it has been said his British statesmen look like Roman senators with English faces. His ideal figures and bass-reliefs are imbued with the spirit of Greek art, for which the sculptor has always professed the profoundest reverence. Refinement of feeling, high poetical imagination, exceeding gracefulness of form and expression, and an almost unrivalled delicacy of execution, characterize this class of his sculptures, of which the "Mars and Cupid" and "Hero and Leander," in the possession of the duke of Devonshire, the "Aurora," "Sappho," "Hebe," "Proserpine," "Sleeping Shepherd," and the "Venus," for St. George's hall in Liverpool, are favorable examples. Gibson is the first of modern sculptors who has had the daring to introduce color into his works. In some of the subordinate details the statue of the queen and the "Aurora" were slightly tinted, but the Venus above mentioned showed the innovation carried to its furthest limit. This statue, which was exhibited in 1854, in a room prepared for the special purpose, is entirely colored of a flesh tint, and the eyes, hair, and parts of the drapery counterfeit the resemblance to actual life as nearly as color can do it. The practice has encountered much hostile criticism, but the sculptor defends it by a reference to Greek precedents. Gibson has seldom visited England, and only for brief periods, the first time being after an absence of 28 years. At Rome, he is a kind and genial adviser of young art students, and beloved by all classes. Among his most recent pupils was Miss Hosmer, the American sculptress.

GIBSON, JOHN BANNISTER, LL.D., an American jurist, born in Shearman's Valley, Penn., Nov. 8, 1780, died in Philadelphia, May 3, 1853. He was a son of Lieut-Col. George Gibson, an officer of the revolutionary army, who fell in St. Clair's expedition against the Indians on the Miami in 1791. He studied at Dickinson college, and previously at the grammar school of that institution, read law under Thomas Duncan, Esq., afterward judge of the supreme court of Pennsylvania, was admitted to the bar of Cumberland co. in 1803, practised successively in Carlisle and Beaver, Penn., and in Hagerstown, Md., returned to Carlisle, was elected by the republican party in 1810 and again in 1811 to the state legislature, in which he filled a prominent station, and in July, 1813, was appointed presiding judge of the 11th judicial district of Pennsylvania. In 1816 he was made associate justice of the supreme court of the

state, and on the death of Judge Tilghman in 1827 he became chief justice. He resigned this position in 1833, but was immediately reappointed to it by the governor. By a change in the constitution, making the judiciary elective, his seat became vacant in 1851, but he was elected associate justice in the same year, being the only one of the former incumbents who received the nomination of the democratic party. He continued to discharge the functions of this office until attacked by his last illness.

GIBSON, THOMAS MILNER, an English statesman, born in 1807. He is the son of Major Gibson, was graduated at Cambridge in 1830, and was a member of parliament for Ipswich and a follower of Sir Robert Peel from 1837 to 1839, when he engaged in the agitation against the corn laws. He thereupon resigned his seat, and remained out of parliament until 1841, when after a violent contest he was elected member for Manchester, and after the passage of the free trade measures in 1846 he became a member of the privy council and vice-president of the board of trade, but resigned that office in 1848. The act to amend the laws relating to the stamp duties on newspapers was passed chiefly through his exertions (June 15, 1855), and he was one of the principal supporters of the law admitting Jews into parliament, which was eventually passed July 23, 1858. He is also a zealous champion of a national system of education. As a member of the peace party he opposed, in concert with his colleague and friend John Bright, the Russian war, which cost him his seat for Manchester at the general election of 1857. In May, 1859, he was reelected as a member for Ashton; and the presidency of the board of trade having been offered to Mr. Richard Cobden by Lord Palmerston, but declined by that gentleman, Mr. Gibson accepted that office.

GIDDINGS, JOSHUA REED, an American statesman, born at Athens, Bradford co., Penn., Oct. 6, 1795. In his infancy his parents removed to Canandaigua, N. Y., where they remained till he was 10 years old, when they emigrated to Ashtabula co., Ohio, among the first settlers in that part of the Western Reserve. In Ohio he had only such facilities for study as he could command in the family circle, in the intervals of hard labor upon his father's farm. In 1812, when less than 17 years old, he enlisted as a soldier for active service, being accepted as a substitute for an older brother. He was one of the expedition sent to the peninsula north of Sandusky bay, where, in two battles on one day with a superior force of Indians, it lost nearly $\frac{1}{2}$ of its number in killed and wounded. At the close of his short term of service as a soldier he commenced school teaching. In 1817 he commenced the study of the law with the Hon. Elisha Whittlesey, and was admitted to the bar in 1820. In 1826 he was chosen a representative to the state legislature, and after serving one term, declined a reelection, and devoted himself to his profession till 1838,

when he was elected to congress as the successor of Mr. Whittlesey. Having been for some years an active abolitionist, and entering congress at a time of great excitement on the subject of slavery, he not only took his stand by the side of John Quincy Adams as a supporter of the right of petition, but became at once a prominent champion of the abolition of slavery and the slave trade in the district of Columbia and the territories under the jurisdiction of the national government. Attentive to all the ordinary duties of legislation, and a frequent participator in discussions respecting the tariff and other current political topics, he yet became distinguished chiefly by the zeal and pertinacity of his opposition to slavery. His first attempt to speak against the slave trade in the district of Columbia was made Feb. 11, 1839, when he was silenced by the enforcement of a rule enacted for the purpose of preventing the discussion of that and kindred topics. On Feb. 9, 1841, he delivered his first anti-slavery speech, upon the Indian war in Florida, which he contended was begun and carried on in the interest of slavery. In the autumn of 1841 the Creole, an American vessel, sailed from Virginia for New Orleans, with a cargo of 136 slaves. The slaves rose upon the master and crew, and, after a brief struggle, in which they killed one man, took possession of the vessel and entered the British port of Nassau, where their right to freedom was recognized and protected. This event created an intense excitement in the United States, and Mr. Webster, then secretary of state, in a letter addressed to Mr. Edward Everett, U. S. minister at London, avowed the intention of the government, in the interest of the owners, to demand indemnification for the slaves. On March 21, 1842, Mr. Giddings brought the subject before congress in a series of resolutions, in which it was declared that, as slavery was an abridgment of natural right, it could have no force beyond the territorial jurisdiction that created it; that when a ship left the waters of any state, the persons on board ceased to be subject to the slave laws of such state, and thenceforth came under the jurisdiction of the United States, which had no constitutional authority to hold slaves; that the persons on board the Creole, in resuming their natural rights of personal liberty, violated no law of the United States, incurred no legal penalty, and were justly liable to no punishment; and that any attempt to reenslave them was unauthorized by the constitution and incompatible with the national honor. These resolutions created an excitement so intense that Mr. Giddings, yielding to the importunities of some of his party friends, who thought the time unfavorable for their consideration, withdrew them, declaring his intention to present them on a future occasion. Mr. Botts of Virginia thereupon introduced a resolution, declaring the conduct of Mr. Giddings, in offering the resolutions, to be "altogether unwarranted and unwarrantable, and deserving the severe condemnation of the

people of this country, and of this body in particular." The previous question being moved, Mr. Giddings was denied the right of self-defense, and the resolution was adopted by 125 yeas to 69 nays. Mr. Giddings instantly resigned his seat and called upon his constituents to pronounce their judgment in the case, which they did in reflecting him by a large majority. He resumed his seat on May 5, after an absence of 6 weeks, and held the post by successive re-elections till March 4, 1859—making his whole period of service 21 years. He was one of the 19 members of congress who, in 1843, united with Mr. Adams in an address to the people of the United States, warning them against the annexation of Texas, and declaring that its consummation "by any act or proceeding of the federal government, or any of its departments, would be identical with dissolution." In 1844 he united with Mr. Adams in submitting a report (upon a memorial from the legislature of Massachusetts), in which it was distinctly declared that the liberties of the people had their primary foundation in the truths of Christianity. In 1849 he made an elaborate speech, in which he maintained that man could not be property, and that to treat him as such is a crime. In the same year, the senate having amended an appropriation bill by inserting a provision extending the laws of the coasting trade to California, with the intention, as was believed, to legalize the trade in slaves between the Atlantic and Pacific coasts, Mr. Giddings, on the last night of the session, called attention to the matter, and succeeded in getting the provision removed. In the Oregon controversy, he maintained the right of the United States to the whole territory, declaring that that right would be sacrificed by the administration for fear that a war with Great Britain would lead to the abolition of slavery. In the celebrated case of the *Amistad*, he maintained the right of the negroes to take their freedom, and zealously opposed the effort to induce congress to indemnify the Spanish claimants. In 1847 he refused to vote for the Hon. Robert O. Winthrop, the whig candidate for speaker, deeming him unsound on the slavery question. He acted generally with the whig party till 1848, giving his hearty support to Gen. Harrison and Henry Clay, but refused, on anti-slavery grounds, to support Gen. Taylor. In the election of 1848 he acted with the free soil party. In 1849 he united with 8 other members of the house in refusing to vote for any candidate who would not pledge himself to such a construction of the standing committees as would secure a respectful consideration of petitions relating to slavery; in consequence of which the whig candidate for speaker, the Hon. Robert O. Winthrop, after a struggle of 3 weeks, failed of his election, the Hon. Howell Cobb, the democratic candidate, being chosen by a plurality of votes. In 1850 he took a prominent part in opposing the enactment of the "compromise measures," so called, especially the fugitive slave law. He was conspicuous also in the de-

bates upon the repeal of the Missouri compromise, and in those upon the subsequent troubles in Kansas. In July, 1850, Mr. Giddings was distinctly charged with abstracting important papers from the general post office. He brought the matter before the house, and demanded an investigation. A committee, composed chiefly of his political opponents, after a rigid examination, exonerated him entirely, it being conclusively shown that the charge was the result of a conspiracy against him. On May 8, 1856, while addressing the house, he suddenly fell to the floor in a state of unconsciousness, from which, however, he soon revived, though in a condition of great weakness. On Jan. 17, 1858, he fell again in the same way, and for some minutes was supposed to be dead. He slowly returned to consciousness, but was compelled for a time to be absent from his post. His disease was an affection of the nervous system operating upon the heart. In 1843 Mr. Giddings wrote a series of political essays, signed "Pacifious," which attracted considerable attention. A volume of his speeches in congress has been published (12mo., Boston, 1858); and in 1858 appeared "The Exiles of Florida," compiled by him and published at Columbus, O.

GIDDINGS, SALMON, a pioneer missionary in Missouri and Illinois, born in Hartland, Conn., March 2, 1782, died in St. Louis, Mo., Feb. 1, 1828. He was graduated at Williams college in 1811, pursued his theological studies at Andover, was ordained to the ministry in 1814, and after being for one year tutor in Williams college and preaching for a short time as an itinerant, determined to go as a missionary to the "western country." He set out on horseback in Dec. 1815, under the direction of the Connecticut missionary society, preached often on his journey, reached St. Louis April 6, 1816, and spent a year and a half in itinerating through the country, visiting most of the towns and settlements on both sides of the Mississippi. On Aug. 2, 1816, he organized the first Presbyterian church in that region, at Bellevue settlement, 80 m. S. W. of St. Louis; and in Nov. 1817, the first in the latter place. Within 10 years he had organized 11 churches, 5 in Missouri and 6 in Illinois. In 1822 he made a long tour among the Indian tribes within the present territories of Kansas and Nebraska, visiting the Osages, Kansas, Omahas, Pawnees, and Ottos, holding councils with their chiefs and principal men, and selecting sites for mission stations and schools. He preached half of the time to the St. Louis church during the first 4 years after its organization, and then more regularly, till in 1826 he was installed its pastor by the presbytery of Missouri, which then included also Illinois. Its first church edifice was erected in 1823-'4. He was remarkable for steadiness of character, soundness of judgment, and fidelity in all offices of kindness and mercy; and the trustees of his church, as a token of their affectionate respect, had his remains deposited in a

vault beneath the pulpit. Only one of his sermons was published; it is entitled "The Gospel the Power of God unto Salvation," was printed at St. Louis, and was the first sermon ever printed west of the Mississippi.

GIDEON, surnamed **JERUBBAAL**, the 5th judge in Israel, was the son of Joash, of the tribe of Manasseh, and dwelt at Ophra. His history is narrated in Judges, vi. to ix. Israel had been for 7 years humbled by the Midianites and Amalekites, when the Lord by a double miracle called Gideon to be their deliverer. Having fulfilled his mission, the Israelites solicited him to become their king, but he declined the position.

GIESLER, **JOHANN KARL LUDWIG**, a German church historian, born in Petershagen, March 3, 1792, died in Göttingen, July 8, 1854. He interrupted his studies in the university of Halle to serve as a volunteer in the campaign of 1813. In 1815 he resumed his studies, which he combined with teaching, and in 1819 was appointed professor of theology in the university of Bonn, which he exchanged in 1831 for the corresponding professorship at Göttingen. His principal work is a history of the church. The 5 volumes published during his lifetime brought the history down only to the peace of Westphalia in 1648; but from the notes and manuscripts which he left, it was continued to the present century by his pupil Redepenning. An American edition of the entire work was published in 1857-'8 under the editorial care of Prof. Henry B. Smith, from the English translation of Davidson. A translation into English was previously made in this country by Francis Cunningham (Philadelphia, 1842).

GIESSEN, capital of the German province of Upper Hesse, and of a circle of its own name in the grand duchy of Hesse-Darmstadt, situated at the confluence of the Wieseck with the Lahn, 41½ m. by rail from Frankfort, and 88½ m. from Cassel; pop. about 9,000. It is well though irregularly built, and contains an old castle, a hospital, arsenal, university, and 2 churches. The university, which was founded in 1607, had in 1858, 45 teachers and 380 students, a library of 34,000 volumes, an observatory, botanical garden, and museum. Its school of organic chemistry under Liebig has recently been especially distinguished. It had a larger number of professors and students prior to the withdrawal of the Roman Catholic faculty to Mentz in 1851.

GIFFORD, **WILLIAM**, an English author, born in Ashburton, Devonshire, in April, 1756, died in London, Dec. 31, 1826. He was left an orphan in early childhood, and apprenticed to a shoemaker. His master refused to allow him to lighten the drudgery of his occupation by reading, but he nevertheless contrived by stealth to acquire a considerable knowledge of mathematics, and occasionally wrote verses. Some of the latter came into the hands of Mr. Oookesley, a surgeon, who raised a subscription to purchase his freedom. He was immediately put under the charge of a teacher, and although, with the exception of mathematics, his attainments were

then almost nothing, in 2 years he was fitted for the university, and entered Exeter college, Oxford, where he was appointed Bible reader. Having accidentally fallen under the notice of Lord Grosvenor, he was invited by that nobleman to live with him, and subsequently spent many years on the continent as the travelling tutor of his son. After his return to England, he published in 1791 his "Baviad," a paraphrase on the first satire of Persius, in which the popular Della Cruscan poetry of the day was happily ridiculed and effectually put down; and in 1795 the "Mæviad," an imitation of Horace, directed against the corruptions of the drama. His "Epistle to Peter Pindar," published in 1800, is one of the bitterest attacks ever directed against an opponent. Being now known as a keen political writer, he wrote with George Ellis and Frere for the "Anti-Jacobin" upon its commencement by Canning, and from this connection received two offices under government, which he held for life. In 1802 he published a spirited translation of Juvenal, with his own autobiography. He also translated Persius, and edited the dramatic works of Massinger, Ben Jonson, Ford, and Shirley. Upon the establishment of the "Quarterly Review" in 1809 he became its editor, a position which he retained until about 2 years before his death.

GIFT, a voluntary transfer of property of any kind. The word "give" is generally employed among the words of transfer in deeds of land; but by gifts, in law, are usually meant transfers of chattels or presents which are wholly without any pecuniary consideration, or any other consideration which the law recognizes as valid. They are usually divided into gifts *inter vivos* and gifts *causa mortis*. The latter are called in English gifts in prospect of death; and the former phrase, or gifts between the living, is not accurate, as describing but one class of gifts, because it applies to all, as only the living can give, and they can give only to the living. But gifts *causa mortis* may be defined as gifts made by one believing himself, on reasonable grounds, to be very near his death, and made in view of and because of this apprehension; and gifts *inter vivos* are all those which are not gifts *causa mortis*.—First, as to gifts *inter vivos*. Any person competent to transact ordinary business may give whatever he or she owns to any other person. The usual disabilities for legal action would apply here. Thus, a gift by an infant (i. e. a minor), a married woman, an insane person, or person under guardianship, would be wholly void, or would be voidable by the giver or one having authority to represent the giver, in much the same way that a transfer for consideration would be. Gifts, by persons competent to give, of property which they have a right to give, to persons competent to receive, and which are completed and effectual, are regarded by the law as executed contracts, founded upon mutual consent. It is absolutely essential to the validity of a gift that it should go into effect at once and completely. If it be

not a thing of the present, now done and finished, then it is no longer an act, but a promise. And as it must be, if a promise, wholly without consideration, because otherwise it is not a gift, it comes under the rule of law which makes promises without consideration of no legal validity, and incapable of legal enforcement. Hence, the very first rule in the law of gifts is, that delivery is essential to a gift. And this delivery must be to the donee; even if the giver deliver the money to a third person with orders to give it to the donee, and will therefore be bound if this third person give it to the donee before revocation, the giver may, at any time before the delivery to the donee, annul his directions to the party holding the money, and revoke and reclaim the gift. Generally, a court having equity powers will not interfere to enforce or complete a gift which is merely intended and promised. Nor will the transfer, if without delivery, be any the more effectual for being made in writing. As there must be actual delivery, so there must be actual acceptance; in other words, the thing given must pass out of the present power and possession of the giver, and into that of the donee. It is nevertheless true that a thing may be given, of which the present and immediate manual delivery is impossible. The delivery may, in such a case, be constructive, or symbolic, or any such delivery as the nature and actual position of the thing at the time may permit and require; as a delivery of a key which commands access to the thing, or a delivery of a part for the whole, where the whole is too bulky to be delivered otherwise. So also the delivery may be by an order upon a warehouseman or other person having the thing in his custody; but in this case the gift is not complete and effectual until the order be presented and completed or performed by the party on whom it is drawn. From the same necessity of completing the gift by delivery and acceptance, and from the same rules which make a mere promise without consideration voidable, it follows that if a gift be made by a note, or any instrument not under seal (for a seal is the equivalent of a consideration), it may be revoked by the donor. So if it be made by a check, draft, bill, or order, the giver may revoke it at any time before it is paid or executed, or accepted in such a way as to bind the drawee. And on the other hand, if any thing of consideration comes in, so as to make the gift while still lying in promise irrevocable, it changes the whole nature of the transaction, which is no longer a gift, but becomes a sale or barter, or an executory and enforceable contract, according to circumstances. A gift by a competent party, made perfect by delivery and acceptance, is then irrevocable so far as the donor himself is concerned; that is, he cannot revoke it and resume his property in the thing given merely at his own pleasure. But it may still be revoked or annulled, and the property resumed, by the creditors of the giver, if it was fraudulent as to them, either in fact or by construction of law.

If the giver knew at the time of the delivery that he could not then pay his debts, the gift was fraudulent in fact; if he were then insolvent, and did not know it, and so innocently by the gift diminished the fund to which his creditors were entitled, it was fraudulent in law. But it is thus void only in reference to existing creditors, and not as to persons becoming creditors subsequently, unless made when the insolvency was actual or immediately expected, or with actually fraudulent purpose as to future creditors. All voluntary transfers, as settlements of every kind and the like, if made in fraud of creditors, are considered as gifts in the law, and are void. In most of the United States the statutes respecting insolvency provide especially for all cases of this kind.—Gifts *causa mortis* can be made only when the donor has reason to believe that death is impending. The law watches over gifts *causa mortis* with great jealousy, and restrains them by rigorous principles and wise precautions, for the same reasons which induce it to lay down such precise and rigid rules in relation to wills and all testamentary dispositions. This reason is not any unwillingness that the wishes of the dead or of the dying should have their full effect, but from the extreme difficulty of giving them this effect, and yet closing the door effectually against, on the one hand, false and supposititious expressions of his will, or, on the other hand, undue and injurious influence exerted upon him as to the disposition of his property. Both of these reasons apply as strongly and directly to gifts made in prospect of death as to wills, or perhaps more so. Indeed, as these gifts are not unfrequently made in substitution of wills, and to avoid the special requirements made by the law in respect to wills, this is another reason why the law regards them with the suspicion felt toward acts which are evasions of law. Much that was said of gifts *inter vivos* is equally or indeed much more strongly applicable to gifts *causa mortis*. Thus, there must be not only delivery and acceptance, but this must be strictly actual, if that be possible without extreme inconvenience; and if impossible, in that case it must be something that is as near actual delivery as may be possible. It has even been said that no mere possession, although previous and continuous, is sufficient without delivery; as if the giver should say: "You may have and keep as your own the watch I have permitted you to wear for a year, and which is now in your pocket," this would not pass the property in the watch unless the giver took it into his own hands and gave it back to the donee; but we doubt whether the rule would be applied with so much severity. We have no doubt that the giver, if physically incapable, or perhaps if only unwilling to make the effort, might, without doing any thing himself, as well and effectually direct another in his presence to take such a thing and give it to such a donee, to be kept by him as his own. After some fluctuation it seems now to be settled that the donor's own note, or his

own check, draft, or bill, not paid or accepted before his death, is not a valid gift *causa mortis*; that is, the executor or administrator of the deceased may refuse to pay his note, and may revoke his bill or draft, and order the drawer not to pay it. But bank notes certainly, and probably all notes of other parties payable to bearer, or endorsed in blank, and perhaps all notes, bonds, and other written contracts of other parties, may be the subjects of a valid gift *causa mortis*, although the law on this subject cannot be regarded as entirely settled. One rule is perfectly certain: one who makes a gift in prospect of death may revoke his gift at any time during his life, although it be completed and executed by delivery and acceptance. Any such distribution of his property is, in the language of the law, ambulatory, or changeable at his own pleasure, so long as he remains alive; and it is sometimes said that his recovery does of itself revoke and annul such a gift made in prospect of death, because the cause and ground of it have ceased to exist. We should say, however, that if the giver, with full means of actual revocation, did not choose to revoke his gift, it became changed by his recovery from a gift *causa mortis* to a gift *inter vivos*. Within these rules and restrictions there seems to be no limit in law to the possible amount of a gift *causa mortis*. It should be added, that gifts in prospect of death are equally void as against existing creditors with gifts *inter vivos*.

GIGNOUX, FRANÇOISQUE RÉGIS, a French painter, born in Lyons in 1816. His art education was acquired chiefly in Paris, where he was under the instruction of Delaroche, Vernet, and other eminent masters. In 1840 he settled in New York, and soon after began to devote himself exclusively to landscape painting. His pictures embrace American scenery under many aspects and at all seasons of the year, winter scenes being favorite subjects with him. Among his best works are the "Dismal Swamp in Autumn," painted for the earl of Ellesmere; "Niagara Falls by Moonlight," in the Belmont collection, New York; and a large picture representing the same scene at sunrise in winter.

GIL Y ZARATE, ANTONIO, a Spanish dramatist, born Dec. 1, 1798. His first successful play, *Un año después de la boda* ("A Year after Marriage"), was performed in Madrid in 1825. His most celebrated works are his tragedy *Gusman el bueno*, and *Carlos II. el hechizado*, a romantic tragedy. He has also written a *Manual de literatura*, of which a 2d edition appeared in Madrid in 1851. A collection of his dramatic works was published in Paris in 1850. In 1832-'3 he was editor of the newspaper *Boletín de comercio*, and is at present chief of a bureau in the ministry of the interior, and professor of literary history in the lyceum of Madrid.

GILA, a river of New Mexico and Arizona, and the principal tributary of the Colorado of the gulf of California. Its sources are in the Mogollon and White mountains (Sierra Blanca), in about lat. 34° N. It flows first S., and then

W. to its junction with the Colorado. For more than one-half its entire length, which is about 450 m., it passes through mountains, and in some places is unapproachable, being buried between walls of perpendicular rock nearly 1,000 feet in height. It emerges from the mountains in long. 111° 25' W., about 25 m. from the villages of the Pimo Indians, after which its course is through an open and comparatively level country to its termination. Its width is scarcely less than 100 feet for half its length, and in many places it expands to from 200 to 800 feet. It has a depth of from 2 to 8 feet, and might be navigated with flat boats as far as the mouth of the Salinas, about 180 m. from the Colorado. There is but little arable land in the valley of the Gila; the best and largest portion is that occupied by the Coco-maricopa and Pimo Indians, which is about 15 m. in length and from 2 to 4 in width. This valley, although occupied by the villages of these semi-civilized tribes, and intersected by the irrigating canals dug by them, is capable of sustaining 5 times their number, if sufficient water could be procured. At times the whole of the water of the Gila is exhausted by these Indians for the purposes of irrigation. Further E., among the mountains, are many luxuriant valleys where formerly existed a considerable population, as is evident from the traces of cultivation and the ruins which remain. Much of the valley or basin of the river below the Pimo villages is filled with sand and incapable of being cultivated. A few m. W. of the Pimo villages the river Salinas discharges itself. This is a clear stream, and more than double the capacity of the Gila. The bottom lands where it joins the Gila are several miles wide, and are well adapted to agriculture. From this valley to the Colorado there is little arable land. Here there is a considerable delta formed by the two rivers, from 8 to 4 m. wide, and thickly covered with wood. The tributaries of the Gila are, on the N., the San Francisco, Benita, and Salinas rivers; on the S., the Suanca or Sanz and the San Pedro; all are small streams except the Salinas. The Santa Cruz river, after a course of nearly 100 m., is lost in the sands of the desert, and seldom discharges its waters into the Gila. The valley of the Gila is in many places covered with the mezquite and cottonwood, and on its margin with the willow. Several varieties of the cactus, including the pitahaya (*cereus giganteus*), grow on the table-land near the river, but never in the alluvial lands in its valley. The ruined edifices, broken pottery, and traces of irrigating canals found along this river, show that its former population was much larger than at present. One of these structures, 12 m. E. of the Pimo villages, is 8 stories high and in good preservation. The others are in a ruined state, and present little more than dilapidated walls, tumuli, mounds, &c., of crumbling adobe, of which the buildings were constructed.

GILBERT, SIR HUMPHREY, an English navigator, half-brother of Sir Walter Raleigh, born in

Dartmouth in 1589, lost at sea in 1584. He was educated at Eton and Oxford, followed the military profession, and was knighted in 1570 for his services in Ireland. Being interested in geographical discovery, both from love of fame and of adventure, he sailed in 1588 with 5 vessels and 260 men prepared to take possession of the northern parts of America, and founded a colony in Newfoundland, which, however, did not prove permanent. On the return his vessel, of only 10 tons burden, foundered in a storm, and all on board perished. He published a book in 1576, entitled "A Discourse of a Discovery for a new Passage to Cathay," to prove the possibility of a N. W. passage to India. He has been called the "father of western colonization."

GILBERT, WILLIAM, an English physician, born in Colchester in 1540, died Nov. 80, 1603. He was educated at Cambridge and Oxford, and was physician in ordinary to Queen Elizabeth. He is chiefly remarkable as the author of a work on magnetism (London, 1600), which, according to Prof. Whewell, "contains all the fundamental facts of the science so fully examined that even at this day we have little to add to them."

GILBERT ISLANDS, or KINGSMILL GROUP, a cluster of 15 coral islands belonging to the Mulgrave archipelago in the Pacific, between lat. 1° S. and 2° 30' N., long. 172° and 174° 30' E.; pop. estimated at 60,000. The largest are Taputeonea or Drummond's, and Taraway or Knox's islands, the former 80 m long by about $\frac{1}{2}$ or $\frac{2}{3}$ of a mile wide, and the latter 20 m. long. Almost the only cultivated products are the cocoanut and pandanus, which form the staples of food, and a species of taro (*arum cordifolium*), highly prized by the natives. The breadfruit is found on the northern, though not on the southern islands. The climate is equable, and though warm is not very oppressive. The inhabitants resemble the Malays. They are well made, slender, of middle size, somewhat darker than the Tahitians, with noses slightly aquiline, large mouths, full lips, small teeth, prominent cheek bones, and fine glossy black hair and beards. The women are much smaller in proportion than the men, and have slight figures, delicate features, and some marks of beauty. The people are divided into 3 classes, chiefs, landholders, and slaves. There is no general authority recognized throughout the group, but there are several kings, one of whom rules over 3 of the islands, while others are scarcely respected in any. In some places the government is administered by public assemblies. The islanders are sullen, passionate, cruel, treacherous, and dishonest. They are fond of war, and are much given to suicide, but they are kind to their children, generous, hospitable, and more considerate of women than is usual among savages. They are said to eat human flesh occasionally, but are not habitual cannibals. Their clothing is made of the leaves of the pandanus; their houses and canoes, though constructed of rude materials, are superior in size, strength, and ele-

gance to any others in the Pacific. The islands have several good harbors, but are seldom visited by vessels.

GILDAS, surnamed "the Wise," the most ancient native historian of Britain, born, according to some authorities, in 493, according to others, in 511, died in 570 or 590. He was the son of Oaw, a British prince who emigrated to Wales to avoid subjection to the Anglo-Saxons, and the Welsh bard Aneurin is supposed to have been either the same person or his brother. His only complete work extant is a short Latin composition on British history, entitled *De Calamitate, Excidio, et Conquestu Britannia*, in which he mourns over the ruin of his country, and inveighs against the British kings and clergy. It was first published by Polydore Virgil in 1525; later editions are by Gale (London, 1684-7), and by Stevenson, under the care of the English historical society (London, 1838), which is much the best. Translations have been published by Habington (London, 1688), and by Dr. Giles in "Bohn's Antiquarian Library" (1848). It is said by Wright that there is no independent authority for the personal existence of Gildas, or for the historical truth of the work attributed to him, which he regards as a forgery of the 7th century.

GILDING, covering the surfaces of bodies with a thin coating of gold, thus giving to them a highly ornamental exterior, that is not liable to tarnish. This method of economizing the precious metal, and imparting to solid bodies the appearance of being wholly composed of it, was practised at very remote periods. The sacred books allude to it; in Exod. xvi. 29 there is a command to overlay boards and bars with gold. That the early Egyptians understood it well is evident from the gilding on the coffins of Theban mummies, in which the gold leaves resemble those now prepared. Homer makes mention of it, and the later Greeks thus decorated the exterior sculpture of their temples and statues. The Romans after the destruction of Carthage applied the process to ornamenting the ceilings of their public buildings, and at last of their private houses also. The thickness of the leaf is spoken of by Martial as like a vapor, and by Lucretius the substance is compared to a spider's web. From Pliny's account an ounce of gold was made into 750 leaves, each 4 fingers square. This is about 3 times the thickness of the leaf now in common use; but some qualities are so thin that 290,000 sheets make a pile only one inch in height; and specimens have been made only $\frac{1}{1000}$ of an inch thick, which is 1,900 times thinner than ordinary printing paper. In modern times the use of gilding in architecture is carried to the greatest extent by the nations of Ohin-India or Further India. It is practised by them with great skill and in the most profuse manner.—Beside the method of gilding by covering with gold leaf, there are processes of modern invention, distinguished as chemical gilding, in which the gold is incorporated with

the substance of the article it covers, and the same quantity is thus made not merely to spread over a much larger surface, but to be permanently attached to metallic bodies, so as to withstand the action of heat and of atmospheric agents without injury—an art incompatible with the attainments of the ancients in chemistry.—Gilding with gold leaf is distinguished as the mechanical branch of the art; and of this there are two distinct processes, one of which is called burnish gilding or gilding in distemper, and the other oil gilding. In the former the article to be ornamented, as the moulding of a picture frame, is received from the joiner before it is made up. A priming of hot size and whiting, carefully prepared of the best materials, and called thin white, is first applied. When dry, all irregularities in the moulding are filled in with the same composition, made of the consistency of putty. Four or five coats of the priming are afterward applied, made thicker than at first, and called thick white, each being allowed to dry before the next is laid on. In these intervals the fine work of the moulding is kept open by the use of suitable scooping tools for this purpose; or the mouldings may be coated at once with two thick whites laid on one upon the other without waiting for the first to dry, and worked into the intricate portions by the aid of hard stones of suitable shape and by the opening tools. The priming, which is now $\frac{1}{4}$ to $\frac{1}{2}$ of an inch thick, is carefully trimmed around the edges and smoothed with pumice stone, and finally with shave grass or glass paper. This is the foundation for the so called gold size—the bed upon which the gold leaf is to be laid—a composition of clay, red chalk, plumbago, suet, and bullock's blood; or, as used by the French, of a pound of Armenian bole to two ounces of red hematite (bloodstone) and as much galena, each ground by itself in water, then mixed and ground with a spoonful of olive oil, and at last tempered with a clear white glue carefully prepared from sheep skins. The former mixture is sold to the gilders. It is of thinner consistency than butter, and when used is first melted with thin size, and then while warm is laid on with a brush. The work is now ready for the gold leaf. The gilder, with a leathern cushion attached to the left hand, on which the leaves are to be spread, and, between the fingers of the same, a knife, camel's hair pencil, and a sort of brush called a tip, by which the gold leaves are to be taken up, opens the book which contains the leaves, and by his breath blows them one by one upon the cushion. With the knife, assisted by the breath, he arranges one leaf, and cuts it into the size he requires for fitting any part of the moulding. He then raises it by touching to it the hairs of the tip, and transfers the slip to the part of the work which has been moistened to receive it, the hollow parts receiving the first applications. If the gold does not adhere to the tip, this is rubbed across the cheek or the palm, when the hairs acquire their proper action. Strip after

strip is laid on with great nicety, each overlapping the preceding one about $\frac{1}{4}$ of an inch, and each carefully pressed down with a camel's hair brush. When the whole is covered and dried, the work is burnished with smooth agates or flints set in handles for this use. The yielding nature of the bed upon which the gold leaf is laid prevents this from being injured in the process. Portions of the work not intended to be polished are passed over without burnishing, and are afterward washed with thin clear size, and when dry are wiped with cotton wool. Any defects in the work are now repaired with more gold leaf, and the article is ready to be returned to the maker to be made up, after which it may again come into the gilder's hands to be retouched in places.—Oil gilding is practised by several different methods; for large objects, especially those exposed to the weather and of metallic composition, the priming used in Paris is white lead mixed with linseed oil and a little oil of turpentine. For equipages and indoor work a varnish polish is much used over the gold. For elaborately designed frames oil gilding and burnish gilding are often employed upon the same piece, care being taken that the applications for the former do not touch the spots intended to be burnished, which are treated in the manner already described. The frames intended for this process are furnished to the gilder made up. They are then thoroughly washed, and afterward receive 2 or 3 coatings of thin white, and more upon the parts to be burnished. A strong size called clear cole is then laid in several coats over those parts only intended for oil gilding, and upon this the oil gold size, a mixture of boiled linseed oil and ochre. By standing over night this becomes ready for the gilding, which is effected without using water. The gold leaf is pressed with cotton wool into all the depressed portions, and when all is laid the work is smoothed over with a brush, by which its irregularities are removed, and the gold is uniformly distributed. Old work is regilded by washing off the old gold and a portion of the gold size, and renewing this as in new work. But oil gilding which cannot be thus removed is well scoured, when it is ready for renewal.—Book covers are ornamented with gilt letters and figures in the following manner. If of cloth, the leaf is laid on over the parts to be ornamented, and the cover is then placed in a press, in which a heated metallic block, having the intended designs cut upon its face, is powerfully pressed against the cover as in printing. The heat of the block causes the glue on the back side of the cloth to melt and come through, and thus fasten the figure to the fabric. Leather covers receive an application of gelatine or of the white of egg dissolved in water, upon which when dry an almost imperceptible application of oil is made with a rag, and the gold leaf is then laid to be pressed as in the case of the cloth. The edges of the leaves are gilded in the bookbinder's press, the same gelatine solution and oil being applied, upon

which the gold leaf is laid and afterward burnished. Chemical gilding is particularly applicable to metallic surfaces, but other surfaces, as of wood, leather, or paper, may be coated with some preparation by which they are rendered fit for it.—Wash or water gilding is the branch of this art in which the gold is applied by means of an amalgam of gold and mercury. In other processes it is deposited from its solution. Copper, or an alloy of copper with a little zinc, or zinc and nickel, or brass, is well suited for the amalgamation process; the nearer the color is to that of gold the better. The surface to be gilded must first be thoroughly cleaned and brightened and freed from oil; and it is then advisable to wash it over with a solution made of 100 parts by weight of mercury in 110 of nitric acid, of specific gravity 1.33, diluted with 25 times the weight of the whole of pure water. This application leaves a coating of mercury upon the metal, which is more ready to take the amalgam than is the metal itself. Both the mercurial solution and amalgam are sometimes applied together by means of the gilder's scratch brush, which is dipped into the former and immediately rubbed over the latter, and then applied to the metal—the process being repeated as often as necessary. After the application the article is washed in water and exposed to glowing charcoal to expel the mercury. The amalgam is prepared by heating small particles of gold to redness and throwing them into a quantity of mercury heated so as to emit fumes, and stirring with an iron rod till the gold is dissolved. There should be about 8 times as much mercury as gold, and the excess of the former is removed by squeezing the amalgam when cold through buckskin. The composition then contains about 57 parts of mercury to 33 of gold. In driving off the mercury, too high or too sudden an application of heat is to be guarded against, and care should be taken to turn the article frequently, that all parts may be exposed alike. While the process goes on the amalgam may be reapplied with a long-haired brush wherever it is needed, the article being taken from the fire for the purpose and immediately returned. The gold thus deposited is of a dull yellow, and still retains some mercury, even though the heat to which the article was exposed caused a drop of water to hiss upon its surface. This excess is removed after washing and scrubbing the article with a scratch brush acidulated with vinegar, by applying the so called gilding wax, and again heating. The wax is a mixture of beeswax with some of the following substances, viz.: red ochre, verdigris, copper scales, alum, vitriol, borax. When the wax is burned off, the color of the gilding is found to be improved, and this is still further heightened by burnishing. The color is also improved by covering the gilt surface with a composition of common salt, nitre, and alum, ground together and made into a paste with water, or dissolved in the water of crystallization of the alum. The metal is then exposed

to heat sufficient to thoroughly melt this composition, which runs over its surface. The piece is then taken from the fire and suddenly plunged into cold water, which causes the saline crust to fall off. It is finally washed with dilute nitric acid, and then with water, and dried. The amalgamation process is not well adapted for gilding articles of iron and steel, an oxide of iron being produced by the acid applications, which prevents the adhesion of the amalgam. For these the best method is to cover them with gold leaf. Copper may be treated in the same way. The metal is heated till it begins to assume a blue color; a sheet of gold leaf is then laid on and gently pressed with a burnisher, and the article is again heated. Other sheets are laid over the first to the desired thickness and heated, and the last is burnished down cold. The surface of iron, whether wrought or cast, or of steel, is sometimes covered with a coat of copper; but the following method of preparing such surfaces for fire gilding is given in Poggen-dorf's *Annalen* for 1846, by R. Boettger. The iron or steel is introduced into a mixture of 13 parts of mercury, 1 part of zinc, 2 of sulphate of iron, 12 of water, and 1½ of hydrochloric acid of specific gravity 1.2, which is then heated to ebullition. The object is soon coated with a film of mercury, upon which the amalgam of gold may be applied in the usual way. By a strong heat the mercury is driven off, together with any zinc that may have attached itself to the iron.—To gild silver, a very good process is that called cold gilding. Sixty grains of fine gold and 12 of rose copper are dissolved in 2 ounces of aqua regia. The whole of the solution is absorbed by linen rags, which are then dried and burned to ashes. The black powder thus obtained is applied upon the silver, which has been annealed and polished, and is rubbed in with a piece of moistened cork or wash leather. Burnishing completes the process.—A method of gilding buttons and other articles by immersing them in solutions of gold was introduced into the establishment of the Messrs. Elkington, in Birmingham, in 1836, by which the injurious effects of the amalgamating process on the health of the workmen were avoided. To a solution of chloride of gold prepared from one part of gold, 80 parts of bicarbonate of potassa are gradually added, and then 80 parts more of bicarbonate dissolved in 200 parts of water. The whole is then boiled 2 hours, and the color of the liquid changes from yellow to green. The articles, being perfectly well cleaned and annealed, are immersed for an instant in a mixture of equal parts of nitric and sulphuric acids, to which, if the gold is intended to have a dead appearance, a little chloride of sodium is added. The articles, washed in water, are plunged in the gold solution, and left half a minute, when they are removed, again washed, and dried in hot sawdust. Articles of German silver, of platinum, or silver, may be gilded by suspending them by copper or zinc wires for a time in the liquid.—For gilding porcelain or

glass, gold precipitated by sulphate of iron is mixed with $\frac{1}{2}$ its weight of oxide of bismuth and a small quantity of borax and gum water, and the mixture is then applied with a camel's hair pencil. The article is heated in a muffle, and when taken out the gold is burnished, and finally cleansed with vinegar or white lead. Vases and articles not exposed to wear may be gilded by fixing gold leaf upon them with copal varnish.—For the most perfect method of gilding, and one which has almost entirely taken the place of the amalgamation process, see **ELECTRO-METALLURGY**. For the process of gilding the backs of books, see **BOOKBINDING**.

GILEAD (Heb. *gal*, mound or heap, *ed*, witness, Gen. xxxi.), the name of a mountain group in the eastern division of ancient Palestine or Perea, extending with various branches nearly over the whole of it. From it the southern districts of the same division were also called Gilead, which is often mentioned in contradistinction to Bashan in the north, but exceptionally also as including the latter region. The cities Ramoth and Jabesh are generally defined by the addition of Gilead as the region in which they were situated. This was rich in pastures, and renowned for its aromatic simples, from which balsam was prepared. Among its rivers were the Jabbok and the Arnon.

GILES. I. A. S. W. co. of Va., intersected by Kanawha or New river; area, about 550 sq. m.; pop. in 1850, 6,570, of whom 657 were slaves, since which time the county has been divided and Craig co. formed out of its N. E. part. Its surface is high and rugged, its mean elevation being 1,600 feet above the ocean; the principal summits are Peter's and Walker's mountains. The soil of the uplands is poor, but the valleys and river bottoms are very fertile. The productions in 1850 were 304,720 bushels of Indian corn, 88,565 of wheat, 68,494 of oats, 1,960 tons of hay, 83,120 lbs. of butter, and 23,591 of wool. There were 17 churches, and 820 pupils attending public schools. Value of real estate in 1856, \$1,179,716. Named in honor of William B. Giles, governor of Virginia in 1828. Capital, Parisburg. II. A. S. co. of Tenn., bordering on Ala., watered by Elk river and some of its branches; area, 600 sq. m.; pop. in 1850, 25,949, of whom 9,358 were slaves. It has a slightly uneven surface, and a fertile, well-tilled soil. The productions in 1850 were 1,857,647 bushels of Indian corn, 81,537 of wheat, 185,804 of oats, 10,801 bales of cotton, 822,487 lbs. of butter (the greatest quantity made in any county of the state), and 10,693 of tobacco. There were 36 corn and flour mills, 16 saw mills, 2 tanneries, 1 newspaper, 54 churches, and 1,123 pupils attending public schools. Capital, Pulaski.

GILES, HENRY, an American clergyman and author, born in Craan-ford, co. of Wexford, Ireland, Nov. 1, 1809. His public education was received at the royal academical institution of Belfast. Educated in the Roman Catholic church, after various changes of opinion he joined the Unitarian body, and officiated as

pastor in Greenock for 2 years, and in Liverpool for 3 years. In 1840 Mr. Giles came to America, where he has been extensively engaged in lecturing, with occasional services in different parishes as a preacher. He has written much for the public press both in Europe and this country; and he delivered 4 of the 13 lectures in the celebrated Liverpool controversy between the Episcopalians and the Unitarians in 1839. His published works are: "Lectures and Essays" (2 vols., Boston, 1845); "Christian Thoughts on Life" (1850); and "Illustrations of Genius in some of its applications to Society and Culture" (1854). As a lecturer and orator, he has spoken to large audiences in the principal cities of the Union for successive winters; has addressed many literary societies and library associations, and given one course of lectures before the Lowell institute in Boston, on the "Genius and Writings of Shakespeare." He has resided with his family for several years in Bucksport, Maine.

GILES, WILLIAM BRANCH, an American statesman, born in Amelia co., Va., Aug. 12, 1762, died at "The Wigwam," in the same county, Dec. 4, 1830. He was educated partly at Hampden Sidney and partly at Princeton college, N. J., though he was not graduated, as he quitted Princeton before completing the usual course. He studied law at Williamsburg, Va., with Chancellor Wythe, was admitted to the bar, and practised for 5 or 6 years with a high reputation as an advocate. He, however, did not like the profession, and abandoned it in 1790 to engage in politics. He was elected by the federal party in the Petersburg district to fill a vacancy in congress occasioned by the death of Col. Bland, and took his seat in Dec. 1790. In Jan. 1791, he opposed the bill for creating a bank of the United States, on the ground that it was little better than a scheme for enriching the bankers at the expense of the public. His course on this question led to his estrangement from the federal party, and to his affiliation with the democrats. On Jan. 23, 1793, he made in the house an attack upon Alexander Hamilton, then secretary of the treasury, charging him with corruption and speculation, and alleging that he had failed to account for \$1,500,000 of the public money. Hamilton vindicated himself triumphantly in a report dated Feb. 4. Giles replied, Feb. 28, by proposing resolutions censuring the secretary for undue assumption of power, and for want of respect for the house. These resolutions were laid on the table by very large majorities; the mildest of them got only 15 votes. In 1796 Giles strongly opposed the creation of a navy and the ratification of Mr. Jay's treaty with Great Britain, and in 1798 the proposed war with France for her outrages on American commerce. In 1798 he declined a seat in congress in order to become a member of the legislature of Virginia, where he coöperated with Madison in procuring the passage of the celebrated resolutions of '98. In 1801 he was again elected to congress. His

career in the house terminated in 1802. He was from the beginning of his service as a member always among the foremost in debate, for success in which he possessed extraordinary qualifications. In Aug. 1804, he was chosen U. S. senator, and continued in that office till 1815. He took at once the position of democratic leader in the senate, and held it till 1811, when he openly manifested his opposition to the administration of President Madison. He abandoned public life in 1815 to attend to his private affairs, and remained in retirement till 1826, when he was induced to become a member of the legislature of Virginia, partly from hostility to the administration of John Quincy Adams, and partly from his strong opposition to the project of calling a convention to revise the constitution of Virginia. He made a powerful speech against this project, in Jan. 1827, which defeated it for a time. In the same year he was elected governor of the state, and held the office for 3 years. The bill for calling a convention was revived and passed at the session of 1827-'8, and Mr. Giles while governor was chosen a member of it. The convention sat in 1829-'30, and he took a distinguished part in its deliberations. Mr. Giles published in 1818 "Political Letters to the People of Virginia," and subsequently various letters on political topics.

GILFILLAN, GEORGE, a Scottish clergyman and author, born at Oomrie, Perthshire, in 1818. The son of a minister of the Secession church, he was educated for the same profession, and has officiated since 1836 as minister of the School wynd congregation at Dundee. His first literary sketches appeared about 1842 in the "Dumfries Herald," and were published in 1845 under the title of a "Gallery of Literary Portraits" (2d ed. 1851). A 2d series appeared in 1849 (2d ed. 1852), and a 3d series in 1855. A new edition of the 1st and 2d series was published in 1854. One of his most successful works was the "Bards of the Bible" (1850; 4th ed. 1856). He has since published "The Book of British Poesy, Ancient and Modern" (1851); "The Martyrs, Heroes, and Bards of the Scottish Covenant" (1852; 2d ed. 1854); "The Grand Discovery" (1854; 2d ed. 1856); "History of a Man" (1856); and "Christianity and our Era" (1857). He has also written a "Discourse on Hades," "Five Discourses on the Abuse of Talent," and a little volume of poems and songs. He is an active contributor to the periodical press, has published an edition of W. O. Bryant's poems, with notes and an introductory essay, and has been connected with various other literary enterprises either as author or editor. Since 1858 he has been engaged in preparing a library edition of English poets with biographical and critical notes.

GILL, a measure of capacity, containing the fourth part of a pint, or 8.665 cubic inches. In London it is commonly called a quartern.

GILL, JOHN, an English divine and rabbinical scholar, born in Kettering, Northamptonshire, Nov. 23, 1697, died in London, Oct. 14, 1771.

He began to preach at an early age, and in 1719 went to London as pastor of a Baptist church at Horsleydown, Southwark, which in 1757 removed to Carter lane, near London bridge, where he continued till his death. He wrote voluminously on doctrinal subjects. His most important work is the "Exposition of the Old and New Testaments" (9 vols., London, 1743-'63), which is especially valuable for its illustrations derived from rabbinical literature. He also wrote a "Treatise on the Doctrine of the Trinity" (1731); the "Cause of God and Truth" (1735-'8), a defence of Calvinism against Arminianism; and a "Dissertation concerning the Antiquities of the Hebrew Language, Letters, Vowel Points, and Accents" (1767).

GILLESPIE, a central co. of Texas; area, 1,980 sq. m.; pop. in 1857, 2,800, of whom 102 were slaves. It has a hilly surface, about $\frac{1}{2}$ part of which is suitable for farming, while the remainder furnishes good pasturage. Iron ore, limestone, and coal are the most important minerals. The staples are cattle, horses, sheep, hogs, and Indian corn, and the productions in 1850 were 15,240 bushels of Indian corn, and 4,880 lbs. of butter. In 1857 the county contained 1,078 horses, and 16,160 head of cattle, 8 saw and grist mills, 4 or 5 churches, and 250 pupils attending public schools. Value of real estate, \$284,200. Capital, Fredericksburg.

GILLESPIE, WILLIAM MITCHELL, LL.D., an American author, professor of civil engineering in Union college, at Schenectady, N. Y., born in New York in 1816. He was graduated at Columbia college in 1834, published in 1845 an entertaining volume entitled "Rome as seen by a New Yorker in 1843-'4," and was called in the same year to the professorship in Union college which he still holds. His work entitled "Roads and Railroads, a Manual for Road-making" (New York, 1845; 7th ed. 1854), is one of the best treatises on the subject. In 1857 he published the "Philosophy of Mathematics," from the French of Auguste Comte, and in 1855 (6th ed. 1858) a highly esteemed work on the "Principles and Practice of Land Surveying."

GILLIES, JOHN, LL.D., a Scottish historian, born in Brechin, Forfarshire, Jan. 18, 1747, died in Olapham, near London, Feb. 15, 1836. He was educated at the university of Glasgow, where he officiated for a time as professor of Greek. After a short visit to London and the continent, he was appointed tutor in Lord Hopetoun's family, and was rewarded with a pension for life. In 1778 he published a translation of the "Orations of Lysias and Isocrates." In 1786 he published in London his "History of Ancient Greece." In 1793, on the death of Dr. Robertson, he was made historiographer royal for Scotland, which brought him a salary of £200 a year. His principal work, beside the above named, is the "History of the Ancient World from Alexander to Augustus" (London, 1807), which was afterward republished as the second part of his "History of Greece."

GILLIFLOWER, the trivial name of a beautiful and fragrant garden plant (*Mathiola incana*, R. Brown), belonging to the *crucifera*, an order comprising many delicate and ornamental species, as well as many useful vegetables, such as the cabbage, radish, mustard, &c. The gilliflower was found on the cliffs east of Hastings, Sussex, England, by Messrs. Borrer and Turner, in 1808, growing in such situations as to preclude the idea that they were other than natural habitats. The gilliflower is strictly a biennial plant, blossoming in the second year, but by care it has been made to survive for several, so much so as to acquire the name of perennial among florists, instances being known of its blossoming until the 6th year from seed. Several distinct varieties have been obtained by cultivation, such as the double or multiplex petalled, with the same colored flowers as the original species, also the scarlet with double flowers, commonly called the Brompton, and the double white branching. Many sub-varieties beside are now known under the names of Brompton and queen stocks, comprising a great variety of beautiful colors, of which the scarlet, the white, and the purple are most esteemed. The successful raising of these requires some care, especially as a profusion of flowers is desirable; in the greenhouse or parlor they are very attractive in the spring months. The most common way to raise them is from seed, although cuttings will root with care; such plants, however, will always prove dwarfish and stunted. The seeds are to be sown in June in drills 8 or 10 inches apart; the soil should be fine, rich, and light, and the seeds should be covered about $\frac{1}{2}$ inch deep. After they are up they should be thinned out occasionally, leaving the young plants about 4 inches apart; they should be kept clean from weeds, and a rapid growth promoted by frequent waterings. Early in July they should be transplanted into small pots, a single plant to a pot, using for soil a good rich sandy loam, and watering them well. Set them aside in a shady place for a week or 10 days, and afterward remove them to a summer aspect, where they may stand till August, when they will need shifting to a pot one size larger. On approach of frost they are to be taken into the greenhouse or sitting room; or if a considerable number are needed for successive blossomings, they can be wintered in well protected frames, or kept in light dry cellars. If repotted toward February for the greenhouse, they will soon come into flower and make a fine show; what remain can be turned out into the open flower border in May, to bloom in June and July. If only a few pots are needed, the process can be modified. After blooming, the old plants can be cut in or headed back, cutting down to a strong leaf, and new blossoms will soon appear. This is advisable sometimes when the seedling plant proves to be a fine sort. Although none but single flowers, or those at least with a few petals, produce any seeds, yet such is the tendency to depart from the normal number of petals, that a large proportion of the plants

have very multiplex blossoms. Doubtless the long cultivation of the species in highly exciting soils has produced this tendency, from which nature is slow to depart. The 10 weeks stock gilliflower (*M. annua*) does not require so much care to bring it to perfection; it is very easily grown, and masses of it planted out in the open border will fill the air with delicious perfume, while they add greatly to the beauty of the garden. The varieties of this gilliflower are almost immense, including what are termed the Russian or close-flowering and the German, which have all hues and tints. These latter are due to the care and patience of the laboring classes in Germany, who bestow great pains upon the rearing of these favorite plants. All the 10 weeks stocks are of less robust habit, are less branching, and are very compact both in foliage and flower; hence their dwarfer style fits them for planting in beds, borders, or masses, at the taste of the florist or gardener. The seeds are to be sown at different periods, if plants are wanted to blossom successively; and 8 or 4 sowings are sufficient from February to August. Of course the two first will be sown in the frame or in the greenhouse; the latter can be sown in shallow boxes or in the open ground. When to be transplanted for indoor flowering, very small pots should be used, as these will answer quite as well and occupy less space. On being required to blossom, they are to be transferred to pots of larger size in soil of three quarters light loam and one quarter well decomposed manure. Though an annual, and coming into blossom usually in a few weeks, whence their name, yet instances are known of their prolonged vitality by a process of shortening in the shoots after the first blooming. The foliage of the gilliflower is usually covered with a soft down or pubescence; but kinds exist where no such pubescence, is found; such are called wall-flower leaved, and are much esteemed. A species in the south of Europe (*M. tristis*) has a very downy aspect in its leaves and stems; its flowers have a sombre hue, are of a dull brown color, not attractive, but on close inspection the petals will be found to have beautiful veinings upon their surfaces. These blossoms are scentless during the day, but redolent with grateful odor on approach of the night. Of this character is *M. odoratissima* (Persian gilliflower) and *M. livida*, from whose dull-colored flowers those singularly hued 10 weeks stocks known as the chamois, cinnamon, clay-yellow, peach blossom, and the like, it is conjectured, have been at some time procured by hybridizing or by similar processes.

GILLRAY, JAMES, an English engraver and caricaturist, born in Chelsea in 1757, died in London, June 1, 1815. He was the son of a Chelsea pensioner, became a student in the royal academy, and about 1784 became known as a successful engraver. Between 1779 and 1811 he published 1,200 caricatures, many of which were etched at once upon the copper without the assistance of drawings. The royal family and prominent cabinet ministers and politicians of the

day were ridiculed by him without mercy. He died of delirium tremens. His works appeared singly, but a collection of them was published in London in 1830, and an edition has since been published by Bohn.

GILMAN, JOHN TAYLOR, governor of New Hampshire, born in Exeter, N. H., Dec. 19, 1759, died in the same place, Aug. 31, 1828. In 1775, on the morning after the news of the battle at Lexington and Concord reached Exeter, he marched with 100 other volunteers to Cambridge, Mass., where he served in the provincial army. Soon after, his father being made treasurer of the state, he became his assistant in the office. In 1780 he was a delegate from New Hampshire to the convention which met at Hartford to take measures for the defence of the country. In 1782 and 1783 he was a member of the continental congress, and in the latter year succeeded his father as treasurer of New Hampshire. He was one of the 3 commissioners appointed by the government of the old confederation to settle the accounts of the different states. In 1797 he was chosen governor, and was annually reelected for 10 successive years. In 1813, '14, and '15 he was again elected governor, after which he declined to be a candidate. He was a zealous federalist, and his popularity in New Hampshire was so great, that he was frequently chosen governor when his party was in the minority. His name is still held in veneration for honesty and patriotism.

GILMAN, SAMUEL, D.D., an American clergyman and author, born in Gloucester, Mass., Feb. 16, 1791, died in Kingston, Mass., Feb. 9, 1858, while on a visit to a married daughter in that place. He was graduated at Harvard college in 1811, studied theology, and was tutor in mathematics at Cambridge from 1817 to 1819, when he married Miss Caroline Howard, and was ordained pastor of the Unitarian church in Charleston, S. C., in which office he remained till his death. He contributed many papers to the "North American Review," "Christian Examiner," "Southern Quarterly Review," and other periodicals, on a variety of subjects connected with philosophy and general literature, and in 1856 published in Boston a volume of "Contributions to Literature, Descriptive, Critical, and Humorous, Biographical, Philosophical, and Poetical." His other prose works are the "Memoirs of a New England Village Choir" (1829), of which 8 editions have been issued, and the "Pleasures and Pains of a Student's Life" (1852). He translated the satires of Boileau, and published some original poems, among which are the "History of a Ray of Light," and a poem read before the Phi Beta Kappa society of Harvard college. He took a prominent part in Charleston in promoting the temperance cause, as well as the interests of literature.—CAROLINE, wife of the preceding, an American authoress, born in Boston, Oct. 8, 1794. She is a daughter of Samuel Howard of Boston, and passed her childhood at

various schools in Concord, Cambridge, and other towns of Massachusetts. At the age of 16 she wrote a poem entitled "Jephthah's Rash Vow," and soon after another on "Jairus's Daughter," which was published in the "North American Review." In 1819 she was married to the Rev. Samuel Gilmer, and removed with him to Charleston, S. C., where she has since resided. She began to edit in 1832 the "Rosebud," a juvenile weekly newspaper, which subsequently took the name of the "Southern Rose," and contained articles of much literary merit. From this periodical she has reprinted at different times the "Recollections of a New England Housekeeper," "Recollections of a Southern Matron," "Ruth Raymond, or Love's Progress," "Poetry of Travelling in the United States," "Verses of a Lifetime," "Mrs. Gilman's Gift Book," and other volumes. The first two of these works attracted particular attention by their practical lessons as well as their genial simplicity and humor, and have passed through many editions. She is especially successful, also, in her books for children. Her later publications are "Oracles from the Poets" (1854), and the "Sibyl, or New Oracles from the Poets" (1854), consisting of passages of verse ingeniously arranged to correspond to numbers which are to be taken at random.

GILMANTON, a post village and township of Belknap co., N. H., 25 m. N. E. of Concord; pop. of the township in 1850, 3,282. It has manufactories of hardware, shoe pegs, carriages, &c., contains a cotton factory, 5 grist and 11 saw mills, 4 tanneries, an academy, and 10 churches, and is the seat of Gilmanton theological seminary, under the charge of the Congregationalists. It was founded in 1835, has 3 professors, 26 students, and a library of 4,500 vols.

GILMER. I. A N. W. co. of Va., watered by Little Kanawha river; area, 512 sq. m.; pop. in 1850, 3,475, of whom 72 were slaves. It has a rough surface, much of which is thickly wooded, and a rich soil, suitable for grain and pasture. There are several salt springs and iron mines. The productions in 1850 were 117,990 bushels of Indian corn, 5,652 of wheat, 22,085 of oats, 1,023 tons of hay, 33,277 lbs. of butter, and 4,961 of tobacco. There were 2 corn and flour mills, 1 saw mill, 1 tannery, 5 churches, and 159 pupils attending public schools. Value of real estate in 1856, \$339,259. Formed from Lewis and Kanawha counties in 1845, and named in honor of Thomas W. Gilmer, member of congress from Virginia. Capital, Glenville. II. A N. co. of Ga., drained by Coosawatee and other rivers; area in 1852, 792 sq. m., and pop. 9,994, of whom 205 were slaves, since which time it has been divided to form Fannin co. on the N. and E. Several spurs of the Blue Ridge, abounding in beautiful scenery, and alternating with fertile valleys, traverse parts of the county. The mineral products, comprising gold, marble, and iron, are valuable and abundant. The staples are grain,

potatoes, and hay. In 1850 the harvest amounted to 214,193 bushels of Indian corn, 24,894 of oats, 20,097 of sweet potatoes, and 5,805 lbs. of rice. There were 2 corn and flour mills, 3 saw mills, 1 tannery, 12 churches, and 205 pupils attending public schools. Named in honor of George R. Gilmer, governor of Georgia in 1880. Capital, Ellijay.

GHILOLO, or ALMAHERA. See MOLUCCAS.

GILPIN, BERNARD, an English ecclesiastic, born in Kentmire, Westmoreland, in 1517, died in Houghton, Durham, in 1588. He was educated at Oxford. At first a Roman Catholic, and a zealous opponent of the reformers, he became a convert to Protestantism after a disputation with Peter Martyr, and in 1552 was made vicar of Norton in the diocese of Durham. On the accession of Mary he went abroad for 8 years. On his return he was kindly received by his uncle, Dr. Tunstall, bishop of Durham, who appointed him his archdeacon, and gave him the living of Houghton, of which he remained rector till his death, declining the bishopric of Carlisle, which was offered to him. His parish and the neighboring neglected parishes, which he regularly visited, comprised a wild rugged district on the Scottish border, whose inhabitants, from centuries of marauding warfare, were in a half savage state. He went fearlessly among them, and by his preaching and benevolence acquired the titles of the apostle of the north and the father of the poor. Such was his hospitality, that every fortnight 40 bushels of corn, 20 bushels of malt, and a whole ox, with ample supplies of other kinds of provision, were consumed in his house; while on every Sunday from Michaelmas to Easter all his parishioners with their families were expected to visit him, 8 tables being constantly set for them. He preached so boldly against the vices of the times, and especially of the clergy, that complaints were made against him successively to the bishops of Durham and the bishop of London. He built and endowed a grammar school in his parish for the instruction of the children of the poor, and regularly educated at his own house 24 lads of promise whom he ultimately sent to the university. His life has been written by George Carleton (London, 1628), and by William Gilpin (London, 1751).

GIMBALS (Lat. *gemellus*, twin), a contrivance by which instruments, as mariners' compasses, nautical barometers, &c., are kept in a proper position for observation, and comparatively quiet, however disturbed the movements of the vessel in which they are carried. It consists of two concentric rings or hoops, one suspended within the other by two pivots opposite each other, and the outer one secured to a box or fixed object. Within the inner ring the instrument is suspended by two opposite pivots placed at right angles to those by which the ring is suspended. It thus swings freely in two directions at right angles, and maintains a vertical position, and when used for the compass card always presents this horizontally.

VOL. VIII.—17

GIN, or GENEVA (Fr. *genièvre*, juniper), an alcoholic liquor, originally made in Holland, and still manufactured there upon a large scale in the distilleries of Schiedam. The great popularity acquired by this liquor has induced many attempts to reproduce it in Great Britain; but the difference between "Hollands" and "British gin" has always been very marked in favor of the former. The following account of the process of manufacture is given by Dr. Muspratt, as furnished to the late Dr. Thomson by a gentleman who spent several years in Holland solely to become familiar with the operation. (For general details of the process, see DISTILLERY.) The grains employed are only rye and barley. Of the former 228 lbs., and of barley malt 112 lbs., are mashed with 460 gallons of water at 162° F.; after infusion has taken place, cold water is added to bring the strength to 45 lbs. per barrel, or specific gravity 1.047, at which strength, after it has cooled to 80° F., it is run into the fermenting tun. To the contents of the fermenting back, which is about 500 gallons, $\frac{1}{2}$ gallon of good yeast is added; fermentation speedily sets in, the temperature rises to about 90°, and the attenuation is complete in about 48 hours. After attenuation of the mash, from 12 to 15 lbs. per barrel of saccharine matter remain undecomposed in the fermented liquor. The mash and grains are then introduced into the still, and the whole of the low wines distilled over; these are subjected to a second distillation, and the distillate after rectification is the famous geneva. A few juniper berries and sometimes hops are added in the rectification, to impart to the spirit a peculiar terebinthine flavor. Dr. Muspratt remarks upon the imperfect attenuation of the worts in this process, and the small amount of yeast employed in bringing about the fermentation. The British and Irish distillers obtain double the quantity of spirits from the same amount of worts, and this, he thinks, together with the great quantity of yeast they employ, may account for the difference in the flavor.—But the common article of British gin is made very differently. The rectifiers of the Scotch and English whiskey employ for its manufacture the faints or impure products of the distillation of this liquor, rectifying it by one or more distillations, and flavoring it with juniper berries and other substances, most of which are aromatics. A number of receipts in use are given by Dr. Muspratt, from the note book of one of the most extensive and respectable distillery rectifiers in the kingdom, to exemplify the "most absurd and uncouth fashion" in which these processes are conducted. One of these receipts is as follows: 960 gallons of spirit, hydrometer proof, 96 lbs. German juniper berries, 6 lbs. coriander seeds, 4 lbs. grains of paradise, 4 lbs. angelica root, 2 lbs. orris root, 2 lbs. calamus root, 2 lbs. orange peel; 80 or 90 lbs. of liquorice powder are occasionally added to impart color and sweetness. Such additions to the spirit are called "gin flavorings." Beside the ingredients named car-

away seeds, cassia buds, crushed almond cake, lemon peel, and sulphuric acid are used in other receipts. For the west country gin, much used in Cornwall, the receipt is to introduce into the still 700 gallons of the second rectification of whiskey faints, and flavor with 14 lbs. German juniper berries, 1½ lbs. calamus root, cut, and 8 lbs. of sulphuric acid. The manufacturing processes, however, furnish but an imperfect indication of this article as actually consumed. As it passes into second hands, it is commonly reduced by adding water, the effect of which is to render the mixture whitish and turbid by precipitating the oily and resinous matters that were held in solution by the spirit. These must either be redissolved or removed by a process of clarification, or, as it is called, "fining." Alum dissolved in water and subcarbonate of potash are commonly employed for the latter purpose. The alumina set free carries down with it as it subsides the finely divided oily matter, which produces the blue color of the diluted liquor, and these are replaced in the solution by sulphate of potash formed in the double decomposition of the two salts. A reprehensible practice prevails of using subacetate of lead in place of the potash salt, by which a soluble poisonous sulphate of lead remains in solution. Gin is fined also by a mixture of alum, carbonate of potash, almond oil, sulphuric acid, and alcohol, by which it acquires the property of "beading," or hanging in drops on the sides of the glass containing it. As diluting with water also reduces the strength and sweetness of the gin, the latter quality is restored by the introduction of sugar, and the former factitiously by adding the peppery flavored grains of paradise or cayenne in the form of tincture of capsicum. Sulphate of zinc (white vitriol) is sometimes employed for the same purpose. The pure Holland gin is subject to similar adulterations.

GINGER, the root of the *zinziber officinale*, a shrub which was first known in Asia, but is now cultivated in the West Indies and Sierra Leone. The stem grows to the height of 3 or 4 feet, and dies annually; the root continues two years. It is dug when one year old, and in the West Indies usually in January and February after the stems have withered. Two varieties are distinguished, called the black and the white ginger; the difference appears to be owing to the greater care exercised in the selection and preparation of the roots of the latter. After being washed, the outer coating or epidermis is scraped off, and the roots are then scalded to prevent germination; they are finally dried in the sun, and are ready for market. The West India or Jamaica ginger, when carried to England, is sometimes further whitened by bleaching with chloride of lime, or the fumes of burning sulphur. The black ginger is not scraped, and the roots are not so well selected. Most of that which is imported from the East Indies is of this character, and such is the article in common use in the United States. Though called black, the color of the powdered root is a light yellowish

brown; that of the white ginger, as imported from Liverpool, is a yellowish white. The young and tender roots are often selected for preserved ginger. This is prepared by removing the epidermis and boiling in sirup. The best ginger is hot and biting to the taste and of aromatic odor; the common article is less decided in these qualities, and by exposure to the air either kind loses them entirely. They may be extracted by water and alcohol. The taste appears to be due to a volatile oil of yellow color, that exists in small proportion in the root, and the aromatic quality to a soft resin. Ginger is employed as an ingredient in various domestic preparations, as beer, sweet bread, &c. Its effect is stimulative, warming, and soothing to the stomach, and for these qualities its use is introduced in medical practice. It is recommended as an excellent addition to bitter infusions and tonic powders. It is externally applied as a rubefacient; and while it excites a considerable degree of heat, it does not discolor or injuriously affect in the slightest degree the most delicate skin. Thus used, it is made into a thin paste with some alcoholic liquor and spread as a plaster. Commercial ginger is frequently adulterated, and is often more than half made up of foreign matters, as ground rice, wheat and potato flour, sago and tapioca. With these turmeric powder is used to preserve the color, and cayenne pepper and mustard are added to disguise the other substances and give factitious strength to the mixture. Of 21 samples examined by Dr. Hassall, 15 were found to be thus adulterated. Inferior qualities are made to resemble the best by bleaching and also by washing in chalk and water. Ginger thus prepared is said to be whitewashed.

GINSENG, the root of the annual shrub *panax quinquefolium*, the genus so named by Linnæus from *panacea*, with reference to the estimation in which the plant is held by the Chinese. The name of the plant among the Chinese and North American Indians very singularly signifies in their respective languages the figure of a man, given it from some fancied resemblance in the root to the human figure. Attention was first called to the plant early in the 18th century by the Jesuit missionaries, who found it in the highest estimation among the Chinese for its supposed medicinal virtues. The right of collecting the root was monopolized by the emperor, and whole districts containing the forests in which it was found were scrupulously guarded against the encroachments of any but the 10,000 Tartars employed by the emperor to collect the root. Each of these, in the year 1709, was bound to furnish 2 ounces free, and to sell the rest to the emperor for its weight in silver, which was not more than ¼ of its value. The article, indeed, was often rated at its weight in gold. Many volumes are said to have been written by the Chinese physicians upon the virtues of the ginseng. They introduced it in almost all their prescriptions for the nobility, with the view of restoring strength to the sick, and

increasing the vigor of the healthy. The root was used to make a decoction, and the leaves for an invigorating tea. The growth of the plant was found to be below the 89th and 47th degrees of latitude, and an account of it being brought to America, it was discovered first in Canada by Father Lafitau, a missionary among the Iroquois, and in 1718 a description of it was published in the "Memoirs" of the French academy. The French soon engaged in collecting and exporting it, and at one time it was impossible to hire the Indians about Montreal and Quebec for any other purpose than gathering this plant. Large profits were made by the early shipments; but the Chinese at last began to question the qualities of the American article, and its price accordingly depreciated. As late, however, as the year 1832, the shipments of ginseng from the United States amounted to 407,067 pounds, valued at \$99,308. The plant has been found in the mountainous portions of the states, in rich and shady woods, from Canada to Tennessee. The principal collections of it for shipment are now made in western Virginia, Pennsylvania, Ohio, Minnesota, and Wisconsin. In Richland co., western Wisconsin, the trade is stated to have amounted to \$40,000 in 1858, and has been estimated at \$80,000 in 1859. In Minnesota the collection of it was undertaken with great zeal in the early part of the year 1859, and immense quantities were sent to the east, although that gathered in the spring is considered far inferior to that gathered in the autumn. Attempts to cultivate it in gardens have proved unsuccessful. It is regarded in this country of no value as a medicine, and if found in the shops of the druggists it is only to supply the demand for its use as a masticatory, some people having a fondness for chewing it. The taste is rather agreeable, being sweet and bitter, and somewhat aromatic and pungent. Its decoction is a lubricating mucilage, with some degree of aromatic warmth. In the materia medica it is classed among demulcents, and resembles liquorice in taste and external qualities more than any other medicine.

GIOBERTI, VINCENZO, an Italian philosopher, priest, and statesman, born in Turin, April 5, 1801, died in Paris, Oct. 26, 1852. His family, originally of the French middle class, had long been established in Piedmont, and had suffered in commerce severe reverses of fortune. He lost his father in infancy, and the piety of his mother prompted him at an early age to choose the ecclesiastical profession. He studied at the university of Turin, received the degree of doctor of theology in 1823, and 2 years later was ordained to the priesthood. Becoming professor of theology at Turin, he spent several years in scholastic retirement, engaged in various studies of history and philosophy, especially in their relations to religion, and laid the foundation of his erudition, which was afterward unrivalled among his countrymen. Religion and patriotism were the twin motives with which he inspired his pupils. On the accession of

Charles Albert he was appointed court chaplain, but resigned the office in 1838. This step and the liberal tone of his university lectures made him suspected as an accomplice of the revolutionary schemes of "young Italy," and he was suddenly arrested. As, however, he had not coöperated with the secret societies, and had even formally refused to do so, he escaped with 4 months' imprisonment, followed by a sentence of banishment. The first year of his exile he spent in Paris, with the design of pursuing his studies of Christian, and especially Italian philosophy, and with the hope that the literary treasures in the reserved parts of the public libraries might be opened to him. In this he was disappointed, and forced by poverty he renounced or postponed his plans of authorship, and went to Brussels, where he was offered by a friend a humble position as teacher in a private school. In this office he remained 11 years. Meantime he obtained ample privileges in the public libraries of that city, resumed his interrupted studies, and produced his philosophical works, the *Teorica del sovrannaturale* (Brussels, 1838), and the *Introduzioni allo studio della filosofia* (3 vols., Brussels, 1840). The mastery displayed in the latter work at once of the highest problems of theology, philosophy, and history, its profound expositions and hostile criticisms of the principal modern philosophical systems, and its brilliant and novel subjection of science to revelation, and of all the culture of life to religion, caused him to be immediately recognized as one of the chiefs of Catholic philosophy. Abandoning the psychological method, which he called the great modern heresy in philosophy, he revived the theory of the ideal vision, "a most ancient doctrine, which sprang up at the origin of the race, was preserved in part by the philosophers of the Orient, was not ignored by Plato, was matured by the Alexandrians, was freed from all mixture with pantheism by the early Christian fathers, especially by St. Augustine, was professed by some illustrious realists of the middle age, and was at last exalted to the dignity of a scientific theorem by Malebranche." Endowed with this vision or super-intelligence, the human mind sees not only the archetypal ideas of things in the supreme mind, but also the creative act which individualizes them in time; communes not only with the speculative divine intellect, but with the practical divine will, and apprehends the miraculous work of creative omnipotence by being a constant spectator of the immanent act of creation. The key to all philosophy and to all knowledge is what he terms the ideal formula *L'Ente crea le esistentiæ* (*Ens creat existentias*: "Being, i. e. God, creates existences"). This formula, as the first, axiomatic, and universal truth, he restores to modern philosophy, and makes it the ontological basis of all dialectics, the *primum philosophicum*. It embraces the universe in the duality of the necessary and the contingent, binds these together by the link of the substantial creation, and reduces them to the primordial unity of a

Being, not abstract or generic, but concrete, individual, absolute, and creative. A substance or first cause, an organic multiplicity of substances or second causes, and a real and free act by virtue of which the creative God unites himself with the world of created existences, are the 8 integral ideal elements which constitute together the ideal organism. They are not only the basis of the whole created order, but reappear in special applications in every fact of nature and every act of human life, God universally entering as creator in the order of second causes. Thus in ethics the ideal formula is: "God, by means of the human will, produces the good," which may be resolved into the two corresponding formulas: "The will, by subjecting the passions to law, produces virtue," and "Virtue, by reconciling the passions with law, produces happiness." He recognizes two cosmic cycles, the one the procession of existences by way of creation from God as first cause, and the other the return of existences to God as final cause. All practical life, all manifestations of created activity, belong to this second cycle; and the absolute and universal law of God, who alone hath true and complete autonomy, directs this process of return, which by reason of sin has become a process of redemption. The law corresponds in the second cosmic cycle to the creative act in the first, and is the means of a moral cosmos, as the latter is of a physical cosmos. In the creative cycle, God is the only agent; in the moral cycle, man coöperates with the divine Actor, imitating him, and aiming to produce under his guidance his own uprightness and happiness. It was rather by the remarkably original form of its statements than by the novelty of its ideas that the *Introduzioni* exerted its influence, and caused Gioberti to be hailed as the reconstructor of modern philosophy. It was quoted with applause in the charges of French and Italian bishops, and, though assailed by a portion of the Catholic press, was examined, judged, and commended by Pope Gregory XVI. Eloquent, passionate, and full of bold and felicitous digressions, it contains more pages on literature, art, and especially politics, than on the philosophical theory which it introduces, and foreshadows the character of a publicist which the author was soon to assume. In his work *Del bello* (Brussels, 1841) he applied his philosophy to æsthetics, defining beauty to be "the individual union of an archetypal idea with a fantastic element made by the æsthetic imagination." In a fine criticism of the *Divina Commedia* he maintains its superiority to all other poems. The first work that made him popularly known was the *Del primato morale e civile degli Italiani* (Brussels, 1848), the object of which was to restore in Italy not only the philosophy of the Christian fathers but the Guelph policy of the papacy. As applied to human society, the ideal formula becomes: "Religion creates the morality and civilization of mankind." This he states to be a truth of universal history, the civil orders having always sprung from the sacerdotal,

cities from temples, laws from oracles, philosophy from theology, and popular culture from religion. Italy is the sacerdotal nation of Roman Catholic Europe, being elected by Providence to guard the second dispensation, as Israel was to guard the first. Hence her precocious mediæval civilization, when the popes exercised civil dictatorship over the monarchs. The rest of Europe being then barbarous, religion was obliged to give a large place to the ascetic and contemplative life, and to institutions of impressive splendor, fit to awe and soften the fierce men who beheld them. But in modern society, when the European nations have attained their majority, and the culture of the enlightened laity is equal to that of the clergy, the study of the latter should be to ally piety with the active life of man, with industry, letters, learning, and all the agencies and ornaments of civilization. He affirms that the priesthood has failed to recognize the changes which have been going on about it, the progress of civil and social culture, and that it has attempted to retain the people in tutelage beyond the proper time, after it has lost its control of them by having lost its former moral and intellectual superiority over them. Hence a fatal schism exists between the ecclesiastical and temporal orders, between spiritual and secular culture, which is the source of all the evils that afflict modern society. The remedy which he proposes is the voluntary cession by the priesthood of a dominion which has become incompatible with modern civilization, and a thorough alliance of sacerdotal and lay culture, a blending of the superhuman excellences of the gospel with the ancient spirit of Athens and Rome, an interfusion of Plato with Dante, Brutus with Michel Angelo, Cato with Hildebrand, and Lycurgus with Carlo Borromeo. He calls upon the Italians and the Italian clergy to inaugurate this new civilization, higher and more exquisite than any that the world has hitherto known, urging the latter to put themselves at the head of social movements, and to be the champions and not the enemies of the demands of the age for free institutions. Italy must renounce the ancient dictatorship, but he claims for the pope an arbitratorship in the affairs of the European nations, founded, however, only on his spiritual authority. By this policy, religion would harmoniously resume its place as the leading influence in society. The programme which he proposed for immediate Italian politics was: a confederation of the states; the introduction of reforms; a religious head, the pope; a military head, the king of Sardinia; a capital, Rome; a citadel, Turin; and above all, a sentiment of nationality in the Italian princes. From the publication of the *Primato*, Gioberti was regarded as the leader of the moderate liberal party; in spirit, aim, and practical tendency he was in sympathy with the party of "young Italy," from which he differed by including among the instruments for reconstructing society his ideal philosophy and the Catholic church. Few works have been re-

ceived with greater enthusiasm, or have wrought a greater influence upon the public opinion of a nation. It was, however, distrusted by the Jesuits, to whom Gioberti replied in the *Prolegomeni* of the second edition (Brussels, 1845). In 1846 he removed to Paris in order to be within reach of the movements of internal reform beginning in Italy. The accession to the pontifical see of Pius IX., who had studied with favor the writings of the exiled philosopher, and the liberal measures which he granted at the same time that constitutional principles were proclaimed by the court of Turin, promised to Gioberti the speedy realization of his ideal. He wrote a severe and passionate answer to the attacks which the Jesuits had made on him, under the title of *Il Gesuita moderno* (5 vols., Lausanne, 1847), the result of which was their expulsion from Sardinia. At the revolution of 1848 he returned to Italy after an absence of 15 years, and was welcomed with a triumph at Turin, the city being illuminated in his honor several nights in succession. Opposed alike to foreign dominion and to a general republic, his scheme was a union of the states under the supremacy of the house of Savoy, and he visited the principal cities of the peninsula, haranguing the troops, the universities, and the populace in favor of his views, and was everywhere received with enthusiasm. Mazzini, the head of "young Italy," was, however, his rival in popularity and influence, and his bitter opponent, and the discord between these two leaders soon extended to the princes, some of whom withdrew the forces which they had sent to aid Sardinia against Austria. Mazzini and Gioberti mutually reproached each other with being a greater enemy to Italy than even Austria. The latter, elected to the Piedmontese parliament (which assembled on May 8) by both Genoa and Turin, placed himself at the head of the constitutional royalist party in the chamber of deputies, and was appointed its president by acclamation. In July he entered the Casati ministry, and for a moment thought that he saw the triumph of his hopes in the vote by which the Lombardo-Venetian provinces were annexed to Sardinia. The military reverses experienced by Charles Albert quickly dissipated the illusion, and the ministry gave place to that of Revel, which accepted an armistice that resembled an abandonment of the war of independence, and therefore was at once unpopular. Gioberti united with his opponents of the extreme democratic party in efforts to overthrow this ministry, and at the same time resumed his idea of a political league, and became president of the society for an Italian confederation, representatives of which from all parts of Italy assembled in Turin on Oct. 10. His conduct won general admiration, even from "young Italy," and he was enthusiastically placed at the head of the cabinet which on Dec. 16 succeeded that of Revel. He had scarcely become master of his position, when he selected his own way of carrying out his views. Though he had announced a new campaign in Lombardy,

he was convinced that it could only be fruitless, and conceiving a sort of *coup d'état*, he broke with the party which had yielded to him and shared with him the ministry, absorbed in himself all the energy and responsibility of the cabinet, and, renouncing the war of independence, resolved to employ the Piedmontese armies in restoring the thrones of the peninsula which had been carried away by the popular commotions. He designed to surround them with constitutional guarantees, and to make them not less liberal than anti-republican. To carry back the pope and the exiled princes in the face of "young Italy," then triumphant at Rome, was a conception worthy of his political daring. Two obstacles prevented his beginning the execution of the plan: the refusal of the Italian princes to trust their restoration to the court of Turin, and the energetic resistance of the other Piedmontese ministers to such a movement. The king himself formally opposed the programme of the philosopher, who, after a remarkable discourse before the chambers, resigned his office on Feb. 21, 1849, declaring that with him had fallen the cause of Italian renovation. After the disaster of Novara (March 28), he entered the new cabinet as minister without a portfolio, and was soon after sent to Paris as plenipotentiary. The mission being hardly more than an honorable exile, he solicited the appointment of a successor, and retired from public life. He resumed his studies, and published his *Del rinnovamento civile d'Italia* (2 vols., Paris and Turin, 1851), in which he criticizes the conduct of parties in the movement of 1848, and affirms that he repents of no counsel which he gave or political act which he performed during his brief public career. The end of his efforts he states to have been "to establish in Italy a Piedmontese hegemony, and in Europe the moral supremacy of Italy." He resided from this time in Paris, and was engaged in a philosophical work on *Protologia*, or first science, when his death occurred suddenly by apoplexy. Gioberti is the subject of an able discussion in "Brownson's Quarterly Review" for Oct. 1850, in which, though the highest eulogy is bestowed on his genius, culture, and the first principles and method of his philosophy, he is criticized for aiming in his speculations, not at the salvation of the soul, but at the advancement of civilization, not at the eternal beatitude, but at the earthly felicity of men and the temporal well-being of nations; as maintaining Catholicity, but not maintaining it for a genuinely Catholic end. It is affirmed that religion, thus considered as a civilizing agent rather than as an instrument of salvation, ceases to be religion, becomes merely human, passes wholly into the secular order, and therefore necessarily loses all power or influence over it; and that from this primal error has sprung the attempt of Gioberti "to unite the world and God, earth and heaven, philosophy and theology, heathenism and Christianity, lay culture and sacerdotal." The attempt is regarded as inconsistent with his own principle that the priest-

hood creates civilization, which is therefore thought subject to religion, and not an independent, coexisting interest to be reconciled or harmonized with it. Gioberti refused to submit to the papal condemnation of his *Gesuita moderno*, and all his works have been placed on the index at Rome. Beside those already mentioned, he wrote letters in French *Sur les erreurs religieuses de M. de Lamennais* (Brussels, 1840), and *Sur les doctrines philosophiques et politiques de M. de Lamennais* (Brussels, 1842), and a treatise *Degli errori filosofici di Ant. Rosmini* (Brussels, 1841), charging both of these philosophers with tendencies to pantheism; *Del buono* (Brussels, 1848), in which he applies his philosophical system to ethics; *Apologia del libro intitolato Il Gesuita moderno* (Paris and Brussels, 1848), and *Operette politiche* (2 vols., Lugano, 1851). A uniform edition of his earlier works was published at Brussels (9 vols., 1848-'5). His posthumous works are now (1859) in process of publication at Paris and Turin, under the editorial care of G. Massari.

GIOJA, FLAVIO, also called GIRA or GIER, a Neapolitan mariner, born in Pasitano near the end of the 18th century. The invention of the compass was long attributed to him; but the use of the magnetic needle, suspended by a thread, was known before his time, and he probably introduced the improvement of fixing the needle on a pivot.

GIOJA, MELCHIORE, an Italian political economist, born in Piacenza, Sept. 20, 1767, died in Milan, Jan. 2, 1829. He studied in his native city at the college Alberoni, particularly mathematics, philosophy, and theology, and received holy orders. He lived in studious retirement till the changes caused in Italy by the victories of Napoleon called him to public life. He declared himself for a republic, advocating the adoption of a constitution for Italy similar to that of 1795 in France. The institute of the Cisalpine republic having proposed the question: "Which of all free governments is the best for Italy?" he answered: "The republican," in a dissertation which obtained the prize. He was subsequently appointed historiographer of the state. His liberal views caused him a temporary imprisonment in 1799. Having lost his situation as historiographer by a treatise on divorce (1803), and been removed from the board of statistics on account of articles criticizing the management of public affairs, he revenged himself by a sarcastic article entitled *Il povero diauolo*, in consequence of which he was obliged to leave Italy. He was recalled in 1818, and intrusted with the elaboration of the statistics of Italy, which work was soon interrupted by the fall of that kingdom with the empire of Napoleon (1814). He then wrote on political, economical, and philosophical questions. Suspected of participation in the liberal movements of 1820, he was arrested by the Austrian government, but set free after 8 months' imprisonment, and continued his literary labors. He was a disciple of Bentham and Locke, and his numerous

works on political economy are among the most important in the Italian language.

GIORDANO, LUCA, an Italian painter, born in Naples in 1682, died in the same city, Jan. 12, 1705. He studied at first under Ribera, and afterward went to Rome and studied under Pietro da Cortona. He painted with unequalled rapidity; which circumstance, as well as the nickname of Fa Presto by which he was sometimes called, was perhaps due to the avarice of his father, an inferior artist, who in Luca's youth sold his works at a high price, and was continually urging him on with the words: *Luca, fa presto* ("Luca, make haste"). He visited Parma, Venice, Bologna, and Florence, leaving everywhere products of his talent and facility. Invited to Madrid by Charles II. in 1692, he remained in Spain 10 years, and executed an immense number of frescoes in the Escorial, and in the churches and palaces of Madrid, Toledo, &c. The skill with which he imitated the manner of other artists gained him the title of the Proteus of painting. Among the most admired of his numerous works are the "Triumph of the Church Militant" in the Escorial, the "Virgin and the Child Jesus" in the Pitti palace at Florence, and the "Judgment of Paris" in the Louvre.

GIORGIONE. See BARBARELLI, GIORGIO.

GIOTTO, called also GIOTTO DI BONDONE from his father, and by some AMBERGIOTTO, the regenerator of Italian art, born at Vespignano, near Florence, in 1276, died in the latter place about 1336. Tradition relates that the painter Cimabue discovered him, a shepherd boy in the valley of Vespignano, in the act of drawing upon a smooth piece of slate the figure of a sheep grazing near him, and was so struck with the genius which the work evinced, that he took him into his own house in Florence and taught him his art. Giotto, who was then about 14 years of age, more than realized the expectations of his master, whom he speedily excelled, and who undoubtedly in the latter part of his life conformed his style to that of his pupil. Art was then feebly struggling to free itself from the trammels of the constrained Byzantine style which pervaded all Italy. Cimabue and Duccio di Siena had indeed attempted to improve on existing models, but to Giotto must be ascribed the honor of giving the first healthful impulse to modern art by rejecting them altogether. He was essentially an innovator, and from the commencement of his career deviated from the practice of his predecessors, not merely in the introduction of natural scenes and expressions, and in the dramatic interest of his groups, but in the minor characteristics of form and color. The symbolic representation of a subject, according to conventional rules, had hitherto been the highest aim of the artist. Giotto first gave life to art by making his works truly reflect his own impressions of nature, and was thus enabled within the short compass of a single life to overthrow an existing style, and to form and perfect another, whose higher development was reserved

for a later age. From the remoteness of the epoch in which Giotto painted, it is not surprising that many of his works have perished; but from the specimens that remain and the traditions of those that are lost it is easy to account for the influence which he exerted over central Italy, from Padua to Naples. Social and political revolutions, the quality of the materials used, the effects of climate, and the vandalism of his own and of later times, have destroyed or hopelessly injured his choicest works. Some of them have been white-washed over, among them his portraits of Dante and other eminent citizens of Florence, one of his earliest works painted on the walls of the chapel of the Podesta, now the Bargello, or prison, in Florence, and which Mr. Richard H. Wilde and Mr. Bezzi brought to light in 1840. These are said by Vasari to be the first successful attempts at portraiture. The record of his life is not very clear, but it is certain that before the death of his master Cimabue his reputation was such that Pope Boniface VIII. summoned him to Rome, where he designed his famous mosaic of the *Navicella*, representing the disciples at sea in a tempest and Christ raising Peter from the waves. It is now in St. Peter's, but frequent restorations have left little of the original work beside the composition. We next hear of him at Padua, where about 1306 he executed in the chapel of the Madonna dell' Arena his series of paintings, 42 in number, representing the life of the Virgin. He here met his friend Dante, then exiled from Florence, to whose influence the allegorical tendency which these and many of his subsequent works exhibit is justly ascribed. An instance of this is afforded in the majestic figures of Poverty, Chastity, and Obedience, representing the 3 vows of the order of St. Francis, over whose tomb they are painted in the famous abbey church of the Franciscan order at Assisi, the repository of so many curious specimens of old Italian art. Thenceforth Giotto was actively employed in many parts of Italy. Popes and kings, cities and monasteries, and noble families without number, were emulous for the possession of his works. Robert of Naples entertained him honorably at his court, where he painted the sacraments for the Incoronata; and he is even said to have followed Clement V. to Avignon, and to have painted there and elsewhere in France. The wonder and enthusiasm which his works excited are perhaps without a parallel in the history of Italian art. It seemed little less than miraculous that an artist should express natural character and emotion in his paintings, and a contemporary writer naively illustrates the feeling of the time by expressing his surprise that in Giotto's pictures "the personages who are in grief look melancholy, and those who are joyous look gay." Boccaccio says that "through Giotto that art was restored to light which had been for many centuries buried." Giotto cultivated also the arts of sculpture and architecture, and excelled in

each. Of his proficiency in the latter the famous Campanile of Florence, erected in 1334 from his designs, is a remarkable instance. His school flourished for upward of a century after his death.

GIOVIO, PAOLO (PAULO JOVIUS), an Italian Latin historian, born in Como, April 19, 1488, died in Florence, Dec. 11, 1552. He studied at Pavia, abandoned medical for historical inquiries, was protected by Popes Leo X. and Clement VII., by Charles V. and Francis I., wielded a venal pen, was loaded with honors and favors, and having lost all that he possessed when in 1527 Rome was sacked by the constable of Bourbon, was rewarded with the bishopric of Nocera. His veracity is not to be relied on. His most important work is a "History of his own Time" in 45 books, 6 of which are wanting.

GIRAFFE. See CAMELOPARD.

GIRALDUS CAMBRENSIS. See BARRY, GERALD.

GIRARD, CHARLES, an American naturalist, born in Mulhouse, France, in 1822. In 1839 he was a pupil of Agassiz, at Neuchâtel, Switzerland, and soon became one of his assistants. While in Switzerland he devoted himself chiefly to the *Nomenclator Zoologicus* and the *Bibliographia Zoologica et Palæontologia*. He accompanied Agassiz to America, and remained his assistant until 1850, in which year he went to Washington, where he has continued to reside. He has published in the "Smithsonian Contributions to Knowledge" the first of a series of monographs, being "Contributions to the Natural History of the Fresh Water Fishes of North America." A memoir of his on the "Embryonic Development of *Planocera Elliptica*" has appeared in the "Journal of the Academy of Natural Sciences" of Philadelphia. The article on reptiles in Stansbury's "Expedition to the Valley of the Great Salt Lake of Utah" is from his pen; also the article on fishes in Sitgreaves' "Explorations of the Zuni and Colorado Rivers;" fishes and reptiles in Marcy's "Exploration of the Red River of Louisiana;" fishes, reptiles, and crustacea, in Gilliss's "Expedition to Chile." The fishes of the United States and Mexican boundary report were described by him; also the fishes in the various Pacific railroad surveys, a large quarto with numerous plates. His "Ichthyological Notices" close, for the present, his labors on fishes. He was associated with Prof. Baird in the investigation of the reptiles in the museum of the Smithsonian institution; he also described the reptiles brought home by the U. S. exploring expedition, his volume being the 20th in the series, and accompanied with a splendid atlas. Various papers of his are published in the "Proceedings of the American Association for the Advancement of Science," in the "Proceedings of the Boston Society of Natural History," and in those of the academy of natural sciences of Philadelphia. A paper on the "Physical Aspects of Life" in the "Proceedings of the National Institute," opens a new field of physio-

logical inquiries, with their application to medicine.

GIRARD, GRÉGOIRE, known as Father Girard, a Swiss educator, born in Freyburg, Dec. 17, 1765, died in the same city, March 6, 1850. After receiving holy orders in 1790, he became curate in his native town, and teacher of philosophy in the Franciscan convent. In 1799, having presented to Stapfer, the minister of art and science of the Helvetic republic, a "Scheme for the Education of Switzerland," he was called to aid in organizing a system of general education. After a short stay at Bern, Father Girard returned in 1805 to Freyburg, where he had been appointed prefect of the primary school. Here he was at liberty to reduce to practice his own ideas, and his school flourished till his fame as an instructor spread over Europe. His aim was to convey moral and religious impressions with every exercise of the memory and reason. Through the influence of the Jesuits after their return to Freyburg, the bishop was persuaded in 1823 to abandon his system and suppress his school. He retired to Lucerne, where he taught philosophy with great success. He returned again to Freyburg in 1835 to complete his *Cours éducatif de langue maternelle, à l'usage des écoles et des familles*, the 1st volume of which had already been rewarded by the French institute with the Montyon prize, and the whole appeared at Paris (3 vols., 1845-'8).

GIRARD, СТЕПЕН, an American merchant and banker, born near Bordeaux, France, May 21, 1750, died in Philadelphia, Dec. 26, 1831. He was the son of a seaman, and following his father's calling sailed about 1760 in the capacity of cabin boy to the West Indies and New York. Rising by degrees to be master and part owner of an American coasting vessel, he accumulated in the course of a few years a sum sufficient to establish him in business as a small trader in Philadelphia in 1769. He married about this time the daughter of a ship builder of that city, but the union was unhappy. Mr. Girard applied for a divorce, and his wife ultimately died insane in a public hospital. Meanwhile Girard trafficked with the West Indies with variable success, until his maritime ventures were suspended by the war of the revolution. He then opened a grocery and liquor shop, at first in Philadelphia, and afterward, during the British occupation of that city, at Mount Holly, where he drove a profitable trade with the American soldiers. In 1780 he resumed his dealings with the West Indies and New Orleans, and some time afterward was in partnership for a few years with his brother John. The connection was dissolved in 1790, Stephen having gained while it lasted about \$30,000. The foundation of his subsequent wealth, however, seems to have been a lease which he took of a range of stores, at a time when rents were much depressed by the war; these he underrented at a large profit. Another source of gain to him was the negro insurrection in St. Domingo. Two of his vessels were

then in one of the ports of the island, and many of the planters placed their treasures in them for safety, but were afterward cut off with their entire families. About \$50,000 worth of property whose owners could not be found thus remained in Mr. Girard's hands. With a remarkable capacity for business and a habit of strictness in money matters, he rapidly multiplied his wealth, and before long came to be recognized as one of the richest merchants in the city. During the prevalence of the yellow fever in Philadelphia in 1793, '7, and '8, when it raged with a violence never before seen in America, Mr. Girard not only made liberal donations of money, but performed in person the duties of physician and nurse, undertook the most disagreeable offices in the hospitals, and for two months kept charge of the hospital on Bush hill. In 1812, having purchased the building and a large part of the stock of the old United States bank, he commenced business as a private banker, with a capital of \$1,200,000, which was afterward increased to \$4,000,000. Beside the benefit which this institution proved to the national currency, it enabled Mr. Girard to make heavy loans to the government in times of public embarrassment; and at one period, during the war of 1812, when out of a loan of \$5,000,000 proposed by the secretary of the treasury only \$20,000 could be negotiated, he subscribed for the whole amount. He had an active agency in procuring the charter of the second United States bank, of which he became a director. He contributed liberally to all public improvements, and adorned the city of Philadelphia with many handsome buildings. His character was a remarkable compound of apparently conflicting qualities. He was frugal and parsimonious, but not avaricious; profuse in his public charities, but stern in exacting the last fraction that was due him. His kindness to sick persons was extraordinary, but he never had a friend. His appearance was very plain. He was uneducated; was a free thinker in religion, and an admirer of the school of Voltaire and Rousseau, after whom he was fond of naming his ships. His property at the time of his death amounted to about \$9,000,000. Comparatively little of it was bequeathed to his relatives. To the Pennsylvania hospital he willed \$30,000; to the Pennsylvania institution for the deaf and dumb, \$20,000; to the orphan asylum of Philadelphia, \$10,000; to the Philadelphia public schools, \$10,000; to the city of Philadelphia, for the distribution of fuel to the poor every winter, \$10,000; to the society for the relief of distressed masters of ships, \$10,000; to the masonic loan, \$20,000; to the city of New Orleans, a large amount of real estate; to the city of Philadelphia, for improvement of its streets, buildings, &c., \$500,000; for the improvement of canal navigation in Pennsylvania, \$300,000. The principal bequest, however, was the sum of \$2,000,000, beside the residue of a certain portion of his estate out of which some legacies were to be paid, together with a plot of ground in Phil-

adelphia, for the erection and support of a college for orphans. The most minute directions were given for the construction, size, and materials of the building, which was accordingly begun in July, 1833, and opened Jan. 1, 1848. It is surrounded by a stone wall 10 feet high, enclosing 41 acres of land laid out in play grounds, grass plots, gardens, &c. The main building is the finest specimen of Grecian architecture in America, and is even said to be the finest of modern times. The outer walls, stair cases, floors, and roof are of white marble; the inner walls of brick. It is in the form of a Corinthian temple, surrounded by a portico of 84 columns, each 55 feet high and 6 feet in diameter. Its length is 169 feet, its width 111 feet, and its height 97 feet. The entrances are on the N. and S. fronts, each door being 16 feet wide and 82 feet high; the E. and W. sides are pierced each by 24 windows. The structure rests on a basement of 11 steps extending around the entire building. A marble statue in the lower vestibule covers the remains of Mr. Girard. There are 5 other buildings within the enclosure, one of which is used as a laboratory, bakery, wash house, &c. The other 4 stand 2 on each side of the main building, and are of marble, each 2 stories high, 125 feet long, and 52 feet wide. The cost of the edifices was over \$1,930,000. As many poor white male orphans as the endowment can support are admitted between the ages of 6 and 10 years, fed, clothed, and educated, and between the ages of 14 and 18 are bound out to mechanical, agricultural, or commercial occupations. By a provision of the will of the founder no ecclesiastic, missionary, or minister of any sect whatever is to hold any connection with the college, or be admitted to the premises even as a visitor, but the officers of the institution are required to instruct the pupils in the purest principles of morality, and leave them to adopt their own religious opinions on their entrance into life. The officers consist of a president, secretary, 2 professors, 5 male and 12 female teachers, a physician, a matron, an assistant matron, and a steward.

GIRARDIN, DELPHINE GAY, a French authoress, wife of the succeeding, born in Aix la Chapelle, Jan. 26, 1804, died in Paris, June 29, 1855. She was the daughter of Mme. Sophie Gay, and a poem written by her when she was scarcely 18 years old gained an extraordinary prize of the French academy. In 1824 she published a collection of *Essais poétiques*. She was accustomed to recite her verses in society, and having extemporized some beautiful lines on the premature death of Gen. Foy in 1825, she was hailed as *la muse de la patrie*, and received from Charles X. a pension of 1,500 francs. On a visit to Italy in 1827 she was elected by acclamation a member of the Tiber academy at Rome, and carried in triumph to the capitol. She married Émile de Girardin in 1831, and produced in 1833 *Napoléon*, one of her most charming poems. She had already begun to write novels. *Le lorgnon*, which appeared in 1831, was succeeded

by *M. le marquis de Pontanges* in 1835, and *La canne de M. de Balzac* in 1836. From 1836 to 1848 she furnished to the *Presse*, under the nom de plume of Vicomte Delaunay, 57 *Lettres Parisiennes* on matters of literature, art, and fashion. The only complete edition of these letters was brought out in 1858, with an introduction by Théophile Gautier. In 1839 she wrote a comedy, *L'école des journalistes*, the representation of which was prohibited by the government. In 1843 her tragedy *Judith*, designed for Rachel, was performed at the *théâtre Français*. Another tragedy, *Cléopâtre* (1847), and the comedy of *Lady Tartuffe* (1853), were also written for that actress. Her comedies, *C'est la faute du mari, ou les bons maris font les bonnes femmes* (1851), and *La joie fait peur* (1854), and her vaudeville *Le chapeau d'un horloger* (1854), were highly successful. Her last novels, *Marquerrite, ou deux amours*, and *Il ne faut pas jouer avec la douleur*, appeared in 1858, and a new edition of the former in 1858. She was celebrated for her beauty and wit, and her drawing room was frequented by men of letters.

GIRARDIN, EMILE DE, a French journalist, born in Switzerland in 1802. The natural son of Count Alexandre de Girardin, registered at his birth under the fictitious name of Émile de Lamothe, he struggled for years before he gained his right name, and it was not till 1837 that his filiation was definitely established by his parents' public avowal. After being inspector of the fine arts under the Martignac ministry, he established two periodicals: *Le voleur*, which pilfered from all the other journals, and *La mode*, a journal of fashion, which enjoyed the patronage of the duchess of Berry. After the revolution of 1830 he established the monthly *Journal des connaissances utiles*, the price of which was only 4 francs (less than 80 cents) a year, which soon obtained the unprecedented number of 120,000 subscribers. Through the agency of this paper, he organized a subscription for the establishment of a model farm, known as the *Institut agricole de Coslbo*, and greatly contributed to increase the number of savings banks through the country. He issued other cheap publications in connection with his monthly, as the *Journal des instituteurs*, at 36 cents a year; a geographical atlas at one cent a map; the *Almanach de France*, at 10 cents a copy; the *Journal des gardes nationales*, and the *Gastronome*, a culinary paper which was found in every eating house and restaurant. He was one of the founders of the illustrated weekly *Musée des familles*, which is still prosperous. In 1835 he projected the *Panthéon littéraire*, a series of 100 large vols. 8vo., which were to embrace a mass of letterpress equal to 1,000 ordinary volumes, and to present in a cheap form the standard works of every country. In 1836 he established the *Presse*, a political daily paper, at a yearly subscription of 40 francs, half the price before paid for such journals. This attempt brought upon him the wrath of nearly all his contemporaries. Both his public and

private life were assailed; he was charged with claiming a name which was denied him, with dishonesty in some of his numerous business transactions, and with unscrupulous ambition in his political course. Having challenged Armand Carrel, and killed that popular journalist in the duel, the clamor against him increased on all sides. He however was undaunted, and succeeded in securing the full possession of his name and a long disputed seat in the chamber of deputies, while he extended the circulation of the *Presse* so as to place it beyond rivalry. His character appeared in his motto: *Une idée par jour*. He supported the Molé ministry against the coalition in 1839, and the ministry of Guizot during most of its duration. In 1846 he was excluded from the chamber of deputies on the ground that he was not a Frenchman. In 1848 he refused to participate in the reform banquets which preceded the revolution. On Feb. 24, during the insurrection, he presented himself at the Tuileries and persuaded the king to an abdication in favor of his grandson, the count of Paris; but it was too late to save the dynasty. He vigorously supported the new order of things, tried to inspire the French people with confidence in it, and became for a while the most popular journalist in Paris. During a few weeks nearly 150,000 copies of the *Presse* were disposed of daily. His independent politics, however, were deemed dangerous by Gen. Cavaignac, who ordered his arrest after the insurrection of June, and kept him 11 days in strict confinement. On resuming the editorship of his journal, Girardin vehemently attacked the rule of the general, and greatly contributed to the election of Louis Napoleon to the presidency, but soon became his opponent, gave his journal a more and more radical and socialistic turn, and after the *coup d'état* of Dec. 2, 1851, was ordered out of France. He afterward returned, but, unable to submit to the restrictions on journalism, sold his share in the *Presse* in 1856 for nearly a million of francs. Although now apparently unconcerned in politics, he is reported to be the secret adviser of Prince Napoleon. The catalogue of his political pamphlets would fill columns; most of them are of a decidedly democratic character. His contributions to the *Presse* from 1836 to 1856 were published in 1858 (12 vols. 8vo.), under the title of *Questions de mon temps*. After the death of his first wife, he married (Nov. 1856) Mlle. Mina de Tieffenbach, daughter of a former Viennese postmaster, who was raised to the rank of countess by the duke of Nassau. In 1859 he furnished an introductory preface to a work entitled *Les départs célèbres*, by A. Oharguéraud.

GIRARDIN, MARC, or, as he signs himself, ST. MARC, a French scholar and journalist, born in Paris in 1801. After completing a successful course of classical studies at the college of Henry IV., in 1828 he competed for a professorship in the university, and brilliantly won the title of *agrégé*, but, on account of his liberal opinions, was not appointed to a chair until 1827. In the

latter year the French academy awarded a prize to his *Éloge de Bossuet*, and he became one of the political contributors to the *Journal des débats*. In 1828 his *Tableaux de la littérature Française au 16^e siècle* was rewarded by another academical prize, which confirmed his reputation as an elegant, witty, and forcible writer and professor. In 1830 he travelled through northern Germany, and during a stay of 8 months in Berlin held friendly intercourse with Gans and Hegel. On his return he was appointed to succeed M. Guizot as professor of history in the faculty of letters, and named master of requests to the council of state. In 1833 he visited southern Germany as far as Vienna; and in 1834 published, under the title of *Notices*, the results of his two journeys beyond the Rhine. He was then called to the professorship of French poetry at the Sorbonne, and elected to the chamber of deputies. His report upon the organization of secondary instruction, presented in 1837, was highly valued; and he took rank among the most useful representatives. He entered at the same time the council of state and the council of public instruction; as a member of the latter board he greatly contributed to the extension and improvement of the system of historical teaching in the French colleges. In 1844 he was elected to the French academy. In 1848 he was designated as minister of public instruction, in the last cabinet attempted to be formed under the monarchy. Since that time he has held his position in the council of public instruction, and at the Sorbonne; he is also still a contributor to the *Débats*, and has lost nothing of his vivacity either as a journalist or as a lecturer. His principal works are his *Cours de littérature dramatique, ou de l'usage des passions dans le drame*, an improved reproduction of his lectures; his *Essais de littérature et de morale*; and his *Souvenirs et voyages*, comprising the notices upon Germany above alluded to.

GIRARDON, FRANÇOIS, a French sculptor, born in Troyes, March 16, 1628, died in 1715. He was furnished by Chancellor Seguier with the means of studying his art in Paris and Italy. He was patronized by Colbert, and received orders from the king for groups and statues in several of the royal palaces and gardens. He was appointed general inspector of sculpture in 1690 to succeed Lebrun. Some of his most celebrated works were destroyed during the revolution. The most important of those that remain are Richelieu's mausoleum in the chapel at the Sorbonne, and his groups of the "Bath of Apollo" and the "Rape of Proserpine" in the Versailles garden.

GIRDLE, a band or belt worn around the waist, usually to confine flowing garments. It was thus in use among the Greeks and Romans, and is still a part of ordinary oriental costume. The cestus or embroidered girdle of Venus and the bridal girdle (*zona virginea*) are celebrated in the classical poets. The ancient Britons used to put girdles marked with several mystical figures about the waist of women in labor,

which they imagined gave immediate and effectual relief. Such girdles were preserved with care till a comparatively late period in the highlands of Scotland. It was also an old English custom for an insolvent person to put off and surrender his girdle in open court, which arose from the practice of carrying the purse attached to it.

GIRGENTI, a province on the S. W. coast of Sicily, about 84 m. long and 22 broad; area, 1,200 sq. m.; pop. 250,000. Its surface is mountainous, with numerous valleys, which are exuberantly fertile, and yield corn, wine, and oil in great abundance. There is good pasturage, and the cheese made here is excellent. The chief mineral productions are bitumen, naphtha, sulphur, and salt. The province is divided into 3 districts, Girgenti, Bivona, and Sciacca.—**GIRGENTI**, the capital of the province, is 58 m. S. S. E. of Palermo. (See **AGRIGENTUM**.)

GIRODET-TRIOSON, ANNE LOUIS (**GIRODET DE ROUSSY**), a French painter, born in Montargis, Feb. 5, 1767, died in Paris, Dec. 9, 1824. He was a pupil of David, and obtained the great prize, which enabled him to go to Rome in 1789. During a residence of 5 years in Italy he sent to Paris the "Sleeping Endymion" and "Hippocrates declining the Gifts of Artaxerxes." On his return to Paris in 1795, he painted portraits of Chateaubriand and Queen Hortense, and several large pictures, as "Danaë," the "Seasons" for the king of Spain, "Fingal, Ossian, and their Descendants welcoming to their Aërial Palace the Manes of French Heroes," and in 1806 his most esteemed work, "A Scene of the Deluge." In 1808 he completed his "Funeral of Atala," in 1810 his "Revolt at Cairo," and in 1819 his "Pygmalion and Galatea." He was an accomplished classical scholar, and left 2 vols. of literary remains.

GIRONDE, a maritime department of France, formerly a part of the province of Guienne, bounded N. by Charente-Inférieure, E. by Dordogne and Lot-et-Garonne, S. by Landes, and W. by the bay of Biscay; area, 3,761 sq. m.; pop. in 1856, 640,757. The surface is almost entirely level, the W. portion being a vast, sandy, arid flat, collectively called the Landes. The chief rivers are the Garonne and Dordogne, which unite to form the Gironde, the Isle, Dronne, Dropt, and Leyre. The climate is temperate, and, except in the Landes, generally healthy. The principal productions are wheat, rye, millet, maize, hemp, fruit, wine, cork, charcoal, turpentine, pitch, and timber. Wine is however the staple product, 55,000,000 gallons being made annually. The most renowned Bordeaux wines are produced in the Gironde. Building stone, salt, and chalk are the principal mineral products. The manufactures include, beside wine, calicoes, muslin, earthenware, paper, leather, glass, tobacco, brandy, beer, vinegar, salt, chemicals, and cordage. Ship-building is extensively carried on in Bordeaux. There are 4 lines of railway, connecting Bordeaux with Paris, Bayonne, &c. Gironde is di-

vided into 6 arrondissements, Bordeaux, Blaye, Lesparre, Libourne, Bazas, and La Réole, which are subdivided into 48 cantons and 544 communes. Capital, Bordeaux.

GIRONDISTS (Fr. *Girondins*), a French political party, which played a conspicuous part in the legislative assembly and the convention. They derived their name from the deputies of the department of Gironde, whom they acknowledged as their leaders. Vergniaud, Gensonné, Guadet, Brissot (from whom they were sometimes styled *Brissotins*), Ducois, Boyer-Fonfrède, Louvet, Pétion, Valazé, Buzot, Barbaroux, Carra, Isnard, Lanjuinais, Condorcet, and Rabaut St. Étienne were the most renowned among their members. Imbued with republican principles, fond of justice and moderation, they enthusiastically promoted the proclamation of the republic (Sept. 1792), but engaged in a deadly struggle against the ultra revolutionary party, called the Montagnards; and although eloquence, talent, and virtue were mostly on their side, they succumbed to the violent assaults of their opponents after having been driven by the current to vote in part and reluctantly for the death of Louis XVI. The Montagnards charged them emphatically with plotting against the unity of the republic and aiming at a federal organization of the country. Twenty-two of them were arrested, June 2, 1793, incarcerated at the Conciergerie, and on Oct. 31 died on the scaffold. Mme. Roland, their inspirer, and her husband followed them soon after (Nov.), the former dying by the guillotine, the latter by his own hand. The other Girondist leaders escaped from Paris, and after vainly attempting to revolutionize several departments, almost all were either taken prisoners and beheaded, or died by their own hands. (See Lamartine, *Histoire des Girondins*, 8 vols., Paris, 1847.)

GISORS (anc. *Gisorium*, *Gisortis*, *Gisortium*, *Casarotium*), a town of France, department of Eure, in a fertile plain on the banks of the Epte, 83 m. E. S. E. of Rouen; pop. 3,597. It is surrounded by gardens and beautiful promenades formed upon the remains of its ancient ramparts. Its castle, most of which is still standing, was a work of great strength, and one of the chief fortresses of Normandy. It was built about the 11th century, but the donjon, an enclosed octagonal structure crowning a high artificial mound, was constructed in the 12th century by Henry II. of England. Under one of the towers is a dungeon, the walls of which are covered with carvings executed with a nail by some unknown prisoner. The parish church is an interesting edifice, presenting a singular combination of styles, and filled with grotesque sculptures. The choir is said to have been built by Blanche of Castile in the 13th century.

GITITH, a word occurring 8 times in the titles of the Psalms (viii., lxxxi., lxxxiv.), and generally supposed to designate a musical instrument. It does not, however, occur in any list of instruments. Gesenius supposed that it was a general name for stringed instruments,

and Carpozov, Pfeiffer, and others, that the songs with this title were sung during the vintage. Redslob has published a treatise on the subject, *De Voce מרים* (Leipsic, 1881).

GIULIO ROMANO, an Italian painter, whose family name was *Prpri*, born in Rome in 1492, died in Mantua in 1546. He was the most distinguished pupil of Raphael, whom he assisted in many of his paintings, and who made him his chief heir and appointed him to complete his unfinished works. After the death of his master, Leo X. and Clement VII. employed him, together with Gian Penni, to finish the history of Constantine in the Vatican, and he executed several works for the public edifices at Rome, was also employed there as architect, and painted his celebrated picture of the "Stoning of St. Stephen" for the church of San Stefano at Genoa. He was afterward invited to Mantua, and engaged both as architect and painter on the Palazzo del Te. The "Defeat of the Titans," in one of the halls of the palace, is one of the best examples of his energetic and often extravagant style. He worked with his pupils on many other edifices at Mantua, and just before his death was appointed to succeed Sansovino as the architect of St. Peter's.

GIURGEWO, a town and river port of Wallachia, on the left bank of the Danube, opposite Rustchuk, and 48 m. S. S. W. of Bucharest; pop. 10,000. Its citadel, the only one of its fortifications remaining, stands on an island in the Danube called Slobotzin, and is connected with the town by a bridge. It is the most important port on the Wallachian bank of the Danube, and carries on a considerable trade with Germany and Hungary. The average annual value of its imports from these countries amounts to £275,000. It was several times captured and recaptured by the Russians and Turks in their various wars, and also in 1853 and 1854. It was garrisoned in 1855 by Turkish and Austrian troops.

GIZZARD. See COMPARATIVE ANATOMY, vol. v. p. 566.

GLACIER (Fr. *glace*, ice), a vast body of ice, filling some alpine valley, down which it slowly moves—the outlet of the snows which accumulate in the elevated portions of the mountain group. Glaciers may be found in all countries where there are extensive tracts of land lying above the level of the snow line of the region. In such localities the snows are ever accumulating, and the temperature not rising sufficiently for any considerable proportion to be melted and flow down, they fill the spaces between the summits, and form what in Switzerland are called *mers de glace*, seas of ice. By the pressure exerted by these vast collections the yielding material is forced through whatever opening is presented for its passage, and the great valleys leading to the base of the mountains are packed full of the solid ice, which results from the snow being solidified by pressure, or by its own melting and freezing again. This, solid as it appears, cannot resist the

accumulative force behind it, but is steadily though imperceptibly urged onward, conforming to all the irregularities of its channel, split sometimes by immovable ledges of rock, which stand like islands in its course, yet closing again below them with no trace of the fissure. These bodies of ice extend down the valleys till they reach a region where the temperature is sufficiently elevated to melt away the supplies as they arrive. Though these have gradually diminished toward the lower extremity of the glacier, so that this has flattened away somewhat like a wedge, and has also become narrower, the termination is frequently abrupt and even inaccessible. It presents an apparently stationary wall of ice, which, though seen to be constantly wasting, may yet by observations continued several days be found steadily advancing still further from the mountain. During the summer, currents of water formed from superficial thaws flow over its surface, at least in the daytime, and fall in cascades into the chasms, which are met with in great numbers extending across the glacier. They continue their course, hollowing out through the lower layers of the ice arched channels, which at the lower end appear like dark caverns extending far up into the icy mass. In high arctic latitudes, where the line of perpetual snow comes down to the sea level, the phenomena of glaciers are displayed upon the grandest scale. Thus they were seen in lat. 79°–80° by Dr. Kane in 1855, spreading over the western coast of Greenland, and sloping so gently toward the water that the effect of an inclined plane was perceived only by looking far into the interior toward the east. In this long range the angle of the slope was from 7° to 15°. Yet the whole icy crust of this portion of the continent was always advancing and stretching itself out into the western bay, where masses of it were constantly detached and floated off as icebergs. From this glacier to the southern extremity of Greenland, a distance exceeding 1,200 miles, Dr. Kane imagines a deep unbroken sea of ice may extend along the central portions nearly the whole length of the continent—a sea "that gathers perennial increase from the water-shed of vast snow-covered mountains and all the precipitations of the atmosphere upon its own surface. Imagine this, moving onward like a great glacial river, seeking outlets at every fiord and valley, rolling icy cataracts into the Atlantic and Greenland seas, and having at last reached the northern limit of the land that has borne it up, pouring out a mighty frozen torrent into unknown arctic space. It is thus, and only thus, that we must form a just conception of a phenomenon like this great glacier. I had looked in my own mind for such an appearance, should I ever be fortunate enough to reach the northern coast of Greenland; but, now that it was before me, I could hardly realize it. I had recognized, in my quiet library at home, the beautiful analogies which Forbes and Struder have developed between the glacier and

the river; but I could not comprehend at first this complete substitution of ice for water. It was slowly that the conviction dawned on me, that I was looking upon the counterpart of the great river system of arctic Asia and America. Yet here were no water feeders from the south. Every particle of moisture had its origin within the polar circle, and had been converted into ice. There were no vast alluvions, no forest or animal traces borne down by liquid torrents. Here was a plastic, moving, semi-solid mass, obliterating life, swallowing rocks and islands, and ploughing its way with irresistible march through the crust of an investing sea." (*"Arctic Explorations,"* vol. i. p. 226.)—The phenomenon of glaciers reaching the sea and becoming icebergs was noticed by Darwin on the western coast of South America, even so near the equator as lat. $46^{\circ} 40' S.$, in the gulf of Penas, Chili. In northern Europe it has been observed in Norway, in lat. $67^{\circ} N.$ Upon the Himalaya mountains the glaciers appear from the accounts of modern travellers to be exhibited in masses of stupendous height, as well as of vast extent. In the *"Himalayan Journals"* of Dr. Joseph Hooker, those of the eastern portion of the range, in the territories of Sikkim and Nepal, are described in detail, and mention is made of one which presents a vertical height of 14,000 feet, the source of which is the great Kinchinjunga, whose summit reaches the elevation of 28,178 feet above the sea. Other gigantic glaciers in the central Himalaya are described by Dr. Thomas Thomson (*"Western Himalaya and Tibet"*), and by Col. Madden and Capt. Richard Strachey, in the *"Asiatic Researches,"* vol. xiv. Iceland, Spitzbergen, the Caucasus, and Altai have their glaciers, which have been described by travellers; but no regions have afforded such convenient opportunities for studying them in detail as the Alps of Switzerland, Savoy, Piedmont, and the Tyrol. Here, in the heart of central Europe, they are found covering in detached portions an aggregate area computed at about 1,484 sq. m. Between Mont Blanc and the borders of the Tyrol there are reckoned as many as 400, of which the greater number are between 10 and 20 miles in length, and from 1 to $2\frac{1}{2}$ miles in breadth. Their vertical thickness is in many places rated at 600 feet; their range is from above the snow line, which is from 7,500 to 8,000 feet above the sea, down to the level of 8,000 to 8,500 feet, thus comprising a vertical descent of from 4,000 to 5,000 feet. Lateral ravines have their glaciers, which join as branches the ice-currents of the great valleys. This interesting region has long attracted the attention of scientific observers. It was studied by De Saussure in the latter portion of the last century, and his views were published in his *Voyages dans les Alpes*. De Charpentier is distinguished among later explorers as the able advocate of the theory explaining the motion of the glaciers, afterward sustained by Agassiz in his great work, *Études sur les glaciers*; and

Prof. James D. Forbes of Edinburgh published in 1843 his *"Travels in the Alps,"* &c., with observations on the phenomena of glaciers made in visits to them repeated in 10 different summers, in which he crossed the principal chain 27 times by 23 different passes. To these might be added the names of many other distinguished naturalists, who have aided not only to develop the true nature of glaciers, but also to apply the phenomena they exhibit to the explanation of past changes upon the earth's surface.—Before presenting some of the results of these investigations, there are other features of interest about glaciers, beside those already pointed out, which should receive attention. As they lie spread over the broad valleys, they appear as fixed and immovable as the rocky cliffs at their sides. The snow which covers them during the winter disappears from their face in the warm days of summer, and thousands of streams are then produced which waste their material; but with the return of winter the covering of snow is renewed, and no change may be perceived in the great mass except such as can be referred to these superficial causes. By comparative observations only, made at different times, is it perceived that the great mass itself moves; and yet there are several circumstances that render this conclusion inevitable to the intelligent observer. The constant renewal of the waste at the lower extremity, already referred to, is one evidence of this. Objects upon the surface, too, are found to be continually moving down, even when their position upon the ice itself is not changed. From the high precipices at the sides masses of rock and stone fall along the edges of the glacier, but it is obvious that they do not remain there in an immovable talus; for where one glacier opens into another the piles of stones next the fork do not terminate as they join at this point, but are continued in a long mound of the same varieties of stone far down the glacier; and as other branches come in, each adds its new mound, till sometimes 4 or even 6 parallel ridges are thus produced. These may come in contact with one another below, and thus be reduced in number, and even be blended with the piles at the edges. In some form, however, the mounds continue to the foot of the glacier; and there ridges of boulder-shaped stones and gravel are seen, which lie in front of the glacier, and are sometimes repeated in nearly parallel lines like the little ridges of sand and drift material along a sea-beach, each one of which marks the limit of some previous high tide. So these great ridges of sand and stones, called *moraines* or *borders*, mark the limits reached by the foot of the glacier at former times; and as the tide marks are all removed when a high-course tide again sweeps far up the beach, so the ridges at certain periods are observed to move on before the advancing glacier, and mix together in a new and larger moraine at a greater distance from the mountains. It is in these periods that the habitable valleys of Switzerland are some-

times invaded by the terrible ice wall. Irresistibly and imperceptibly it is found advancing upon the farms and cottages. The warm summer weather is obviously hastening its dissolution, yet its dimensions do not sensibly diminish. The green forests slowly disappear before it; and the growing wheat almost feels its icy touch, before the soil is lifted by its ruthless ploughshare. When, after such an advance, the glacier recedes to its former bounds, the surface it covered is found to be changed into a dismal waste of loose stones.—The gathering and distribution of these materials by action of glaciers have been subjects of special interest, from the resemblance in most of the phenomena exhibited to those connected with the distribution of the geological formation known as the drift. The loose rocks are worn into the rounded forms of boulders, and are similarly striated and grooved upon their surface, and sometimes polished. The rocks upon and against which the glaciers have pressed are found, wherever exposed to view, to be ground smooth and deeply marked with lines corresponding in direction with the course of the glacier at the spot. The surface of Greenland, could it be seen, would unquestionably display these features upon a scale more commensurate with that presented by the drift formation. It is upon these resemblances, and others connected with minor details of the two classes of phenomena, that the glacial theory of Venetz and De Charpentier, so fully elaborated by Agassiz, is based, accounting for the distribution of geological formations like the drift. The transporting power of glaciers was recognized by Prof. Playfair of Edinburgh as far back as the year 1816, and the occurrence of the enormous boulders on the Jura was attributed by him to glaciers, the track of which he supposed lay at one time across the valley of Switzerland and the lake of Geneva, which now separate the Jura from the opposite summits of Mont Blanc. It is on these summits, at the distance of from 70 to 80 miles, that are found the ledges of granite and other rocks, which are recognized as identical with the great boulders scattered over the surface of the Jura limestone.—The quantity of stony material, and the enormous size of the masses of rock carried along by glaciers, is little appreciated, even by many who have seen the loads apparently quietly resting on their surface. Sometimes the ice is almost concealed by the accumulated piles of stone which cover it. These do not sink into the ice, except as they occasionally fall into the chasms, and even then they are sometimes brought again to the surface by the action of the forces which keep most of them there. As the rock protects the ice beneath it from the melting action of the sun, which has its effect around, the rock is thus gradually lifted upon a pedestal of ice, at the same time that the whole is slowly moving down to a lower level. When the pedestal at last gives way, the rock slips down and the process is repeated. When once

in the ice, the superficial melting may bring it again to the surface. The size of the fragments is often immense. Prof. Forbes saw one in the valley which must have been brought down by the glacier, the dimensions of which were nearly 100 feet in length and from 40 to 50 in height; and at the foot of the glacier of Swartzburg in the valley of Saas was another estimated to contain 244,000 cubic feet, requiring an average diameter of nearly 62 feet.—The rate of progress of glaciers, dependent upon various conditions, is no more uniform than that of rivers. It can in no case be correctly estimated except by observations extending over many years. On the glacier of Aar, M. Hugi erected a hut in 1827 at the foot of a fixed and well known rock. In 1836 the hut was 2,200 feet from the rock, and in 1840 this distance had doubled. In the first period its progress had been 250 feet per annum, and in the second 550. Prof. Forbes in 1842 found the remains of a ladder, which, it is believed, was the one left by De Saussure in 1788 at a point 16,500 feet further up the glacier. If so, its yearly progress had been at the rate of 875 feet. This movement extends through valleys in which the surface of the glacier appears to lie almost upon a dead level. It is made manifest day by day by a row of stakes set up in a straight line across the glacier, and ranging with fixed points on the land at the sides. These are after a time observed to lie upon a semi-circular line, the stakes near the centre moving faster than those near the margin. The importance of correctly estimating the rate of movement at short intervals and in different parts of a glacier, in order to determine the nature of the motion, appears to have been first appreciated by Agassiz in 1841, and by Prof. Forbes, who was engaged about the same time in his explorations. Agassiz discovered that the central portion moved faster than the marginal, and he was the first to correct the erroneous views into which he had been led with others on this point, from the fact of the great cracks generally lying in curved lines with the convexity directed up the course of the glacier. (*Système glaciaire*, by Agassiz, Guyot, and Desor, p. 462.) Prof. Forbes, by careful instrumental observations made in 1842, detected the rate of movement in periods of 24 hours, and was able even to notice that which took place in the short space of an hour and a half. He proved the faster rate of motion of the central portions, and also that the portions of the glacier near the surface moved faster than those near the bottom. The rate of motion he found was greatest on the slopes of greatest descent; in warm weather more rapid than in cold; yet always continuous, and not exhibited in the manner of jerks. Such facts are opposed to the theory of De Saussure, that the glaciers move by slipping along upon their bed, the motion being made more easy by the buoyant property of the water flowing beneath them, and the propelling force being that of gravitation. More-

over, the ice, without being broken up, was observed not to be interrupted in its movement by the contracted passages through which it was sometimes forced to pass, nor by solid hills of rock, which lay like islands in its path. The theory maintained by De Charpentier, and supported by Agassiz in his *Études sur les glaciers*, was that the glacier slid upon its bed, not necessarily in large bodies pushed on by gravitation, but that different portions were impelled by different degrees of force, arising from the expansion of the water congealing in all the fissures and capillary tubes of the ice into which it found its way. The facts developed by Prof. Forbes—that the motion was greatest in the warm summer weather, when the temperature did not descend below the freezing point, and that it did not cease when the ice was no longer liquefied in the cold of winter—demanded some new explanation. With the other phenomena they were regarded by him as sufficient to establish the fact that ice in large bodies is not a brittle solid, but that it possesses, particularly when saturated with water, so much plasticity, that with time it can yield to a stupendous and steadily exerted force, and move somewhat like a body of viscous pitch or lava, which, while it appears brittle when suddenly struck, can yet mould itself in the mass to the surface upon which it rests. By this theory, which was generally received even by those who first opposed it, all the difficulties attending the explanation of the movement disappear. It was confirmed by a simple experiment made by Mr. Christie, secretary to the royal society. He filled with water a 10-inch hollow shell of iron, the shell itself being beside $1\frac{1}{2}$ inches thick, and exposed this to severe cold. As the water expanded in freezing, a cylinder of ice was pushed up through the fuse hole, and it continued to increase in length as the water continued to freeze. As the outer portions of the water must have been first converted into ice, it is plain that it was this so called solid material which was forced through the narrow aperture and made to assume the form of a cylinder of its diameter. But the peculiar nature of this quality of mobility belonging to ice has been more perfectly explained, together with some of the other phenomena of glaciers, by the recent researches of Professors Tyndall and Huxley of the royal institution, an account of which is published in the "Philosophical Magazine," vol. xv. (4th series), 1858. The property of particles of ice when exposed to higher temperatures than the freezing point to adhere, and under pressure to unite in one mass, was observed by Prof. Faraday, and was afterward made the subject of various experiments by Messrs. Tyndall and Huxley. They found that compact transparent ice might be crushed to fragments, and these be made by a hydraulic press to assume in a few seconds of time the shape of any mould, recovering in their new form perfect solidity and transparency. A straight bar of ice was also bent into a semi-

circular form by using a succession of 4 moulds of gradually increasing curvature. As the prism conformed itself to these, cracks were produced, and crackling sounds were emitted, reminding one of those which are so often noticed among the phenomena of glaciers. It is by reference to this before unobserved property of ice that the movement and unbroken continuity of glaciers and of their branches are now explained.—The glaciers from their very source present a series of changes of structure, which have been critically observed and traced, and in some instances illustrated and explained by experiments on a small scale with other materials. The snowy region, known by the French term *nevé*, is formed of dry and granular snow, which extends for miles, sometimes broken up by chasms of immense dimensions, and at others presenting no irregularities of surface such as are common to the glacier below, no streams, crevices, moraines, or cones. The snow lies in strata, which reach to great depth, each representing the accumulation of a single year, and the lowest observed the most dense and approaching the blue color of ice. These bodies move onward to form the glacier proper; and as they pass into this, their material assumes more and more the character of compact ice. But a remarkable and peculiar feature is the veined or laminated structure, real, or apparent only, which it assumes. This is noticed in the walls of the fissures, and is also displayed upon the surface of the glacier itself, when this has been wasted by rain. Thin laminae of transparent blue ice alternate with others of white porous ice, and standing together in a vertical position the edges of the former project a little above those of the latter, which more readily melt, and thus a ribbed appearance is produced. The direction of the laminae is across the fissures, and as observed by Professors Tyndall and Huxley these are produced at right angles to the direction of greatest tension. They find an analogy between the lamination of the ice and the slaty cleavage of the clays and slates, both which they refer to pressure causing the development of divisional planes in lines approximately at right angles to the direction of pressure. Hence the obliquity of the lamination to the sides of the glacier as the lines extend from the margin toward the centre and down its course; and the deviation directly across the glacier, or at right angles with this and parallel with its axis, as the form of its bed or other causes produce a pressure in the one case exerted longitudinally and in the other laterally with the line of the glacier. It was by submitting plastic materials, as wax, to pressure, and observing the laminated structure these assumed, that these gentlemen were led to this explanation of the phenomenon as developed in glacier ice; but others, as Prof. Forbes, describe the white ice as produced merely by lines of cavities or of air bubbles in the blue ice itself, the result, according to the observation of Prof. James Thompson, of partial liquefaction induced

by pressure; and Prof. William Thompson attempts to prove "that the first effect of pressure not equal in all directions on a mass of snow ought to be, according to the theory, to convert it into a stratified mass of layers of alternately clear and vesicular ice, perpendicular to the direction of maximum pressure." But the complete explanation of this structure will require experimental researches upon ice which have not yet been made.—Another interesting feature in the appearance of glaciers, to which attention was first directed by Prof. Forbes, is the distribution of what he called the dirt-bands, discolored streaks seen upon the surface, which he supposed were connected with the veined structure, appearing where this is more energetically developed than elsewhere, and caused by the collection of sand and dirt in the decomposed portions of the softer laminæ. These are arranged in curves, the convexity of which is turned down the glacier, and are frequently so obscure that they are distinguished only by looking down upon them from some elevation. Professors Tyndall and Huxley describe them as spread out upon the smooth ice below ice cascades, and were able to cause a similar symmetrical arrangement of dark-colored sand distributed upon the surface of a current of fine mud, which they made to flow from a reservoir down an inclined trough, through a narrow channel, which spread out below over a widened area.—Various other phenomena connected with the structure and motion of glaciers are discussed in the treatises upon this subject already referred to. The latest publication is by Prof. James D. Forbes, entitled "Occasional Papers on the Theory of Glaciers, now first collected and chronologically arranged, with a Prefatory Note on the Recent Progress and Present State of the Theory" (Edinburgh, 1859).

GLACIS, in fortification, the superior slope of the parapet of the outer breastwork or covered way, descending by a gentle declivity to the level ground. It must be protected at every point by the guns and musketry of the fort.

GLADIATORS (Lat. *gladius*, a sword), in Roman antiquity, men who fought with each other at the public games, for the entertainment of the spectators. They were originally captives, slaves, or condemned criminals; but under the republic free-born citizens, and under the empire knights, senators, and even women, fought in the arena. Those who were malefactors were divided into 2 classes, those condemned *ad gladium*, to be killed within a year, or *ad ludum*, who were discharged if they survived till the expiration of 3 years. Professional gladiators were trained in schools at Rome, Capua, and Ravenna, by overseers (*laniste*), who either purchased and maintained them to let them out for public exhibitions, or only trained them for their owners. Claudius and Milo employed gladiators as a political force in their struggle; Cæsar had 5,000 of them at Capua, who were not overlooked by Pompey.

They were taught the postures to be assumed in falling and in dying, and such food was chosen as would thicken their blood in order to give the spectators a more leisurely view of their death. The public combat began with weapons of wood, which were soon exchanged for deadly arms. According to their arms or modes of fighting, gladiators were divided into numerous classes. Usually they were matched by pairs. The *andabata* fought blindfolded, the *catorarii* in troops, the *essellarii* in chariots, the *equites* on horseback, the *hoplomachi* in full armor, the *laqueatores* with the lasso, the *mirmillones* with the weapons of the ancient Gauls, the *Samnites* with those of the people of Samnium, the *Thracæ* with a dagger and round buckler. The *retarii* were lightly equipped, and fought by throwing a net lasso-fashion over the head of their antagonist, and then despatching him with a three-pointed lance or trident. If a combatant was vanquished, but not killed, his fate depended on the people, who turned their thumbs down if they wished him to be spared. A man who had once been a gladiator was always regarded as disgraced, and, if a knight, could not resume his rank. Gladiatorial contests were first exhibited at Rome in 264 B. C., as an entertainment at funerals, and they continued till the reign of Honorius (A. D. 404), when Telemachus, a Christian monk, rushed between two contending gladiators at Rome, and by his self-sacrifice occasioned the decree for their abolition. The passion for them had risen to its height under the emperors. Titus ordained a combat of 100 days, and Trajan one of 128 days, in which 10,000 gladiators fought, and 11,000 fierce animals were killed. Rome was imperilled in 73 B. C. by a rebellion of gladiators under Spartacus.

GLADSTONE, WILLIAM EWAERT, a British statesman, born in Liverpool, Dec. 29, 1809. He is the 4th son of Sir John Gladstone, a wealthy merchant, who relinquished a small business in Glasgow about 1785, and removed to Liverpool, where he acquired a large fortune in the West India trade, and was created a baronet June 27, 1846. At the usual age the son was sent to Eton, where he contracted with the present duke of Newcastle, then earl of Lincoln, a warm friendship, which is commemorated by Benjamin Disraeli in his novel of "Coningsby," and which has remained unbroken to the present hour. Mr. Gladstone's career at Eton gave full promise of the special brilliancy which marked his subsequent academic course at the university of Oxford, where he was graduated at Christ-church in 1831, as double first class, the highest honor, and one rarely attained; after which he became a fellow of All Souls'. After travelling for a short period he entered parliament in Dec. 1832, as member for Newark, a nomination borough belonging to the duke of Newcastle; which position he retained until 1847, when he became a representative of the university of Oxford. In Dec. 1834, he was appointed by Sir Robert Peel a lord of the treasury, and in 1835

under secretary for colonial affairs, which office he filled but for 2 months, when the government to which he belonged was overthrown. He continued a useful and active as well as brilliant member of the opposition party led by Sir Robert Peel, until that statesman's return to power in 1841, when he was sworn a member of the privy council and appointed vice-president of the board of trade and master of the mint. In this position he explained and defended in parliament the commercial policy of the government, and the revision of the British tariff in 1842 was almost entirely his work. He did not, however, confine himself to political labors. He was a constant contributor to the "Quarterly Review," chiefly on literary and ecclesiastical subjects. He also wrote during this period his work on church and state, which created so much sensation, and the extreme high church views maintained in which afterward considerably hampered his political career. In May, 1843, he succeeded Lord Ripon as president of the board of trade, but in Feb. 1845, he resigned his offices on the introduction of the measure for the increase of the Maynooth grant, which was directly opposed in principle to the opinions he had expressed in his work on church and state. In Nov. 1845, Sir Robert Peel resigned, but, on the failure of Lord John Russell to form a government, owing to a difference between Lords Palmerston and Grey, he was recalled and reconstructed his cabinet, Mr. Gladstone becoming secretary for the colonies in the room of Lord Stanley (now earl of Derby). In the free trade measure announced by Sir Robert Peel in Jan. 1846, Mr. Gladstone fully concurred with the ministry; but being unwilling to remain under obligations to the duke of Newcastle, he felt himself constrained to resign his seat for the borough of Newark, and was consequently out of parliament during the debates on this measure. At the general election of 1847 he was chosen to represent the university of Oxford, and one of his first speeches in parliament was in favor of the Jew bill, which he had opposed in 1841. His speech against the foreign policy of Lord Palmerston in the Don Pacifico debates was generally regarded as one of the most admirable pieces of English eloquence the last half century has heard. In the ministerial crisis of 1852 he was invited by Lord Derby to enter his cabinet, but declined, and on the overthrow of that minister in Dec. of the same year accepted the office of chancellor of the exchequer under the earl of Aberdeen. While holding this office he introduced in 1853 his celebrated budget in those remarkable series of addresses which were eulogized by Mr. Cobden, and pronounced by Lord John Russell "to contain the ablest expositions of the true principles of finance ever delivered by an English statesman." On the resignation of Lord Aberdeen in Feb. 1855, and the elevation of Lord Palmerston to the premiership, Mr. Gladstone continued to hold his office of chancellor of the exchequer;

but he soon resigned, together with Sir James Graham, Mr. Sidney Herbert, and the other Peelite members of the government, in consequence of Lord Palmerston's refusing to oppose a motion of inquiry into the conduct of the Crimean war, which was considered indirectly to convey a censure on the duke of Newcastle and Mr. Sidney Herbert. On the overthrow of Lord Palmerston's government and second accession of Lord Derby to power, Mr. Gladstone again declined the pressing overtures of that nobleman, but, in Nov. 1858, accepted an appointment as lord high commissioner extraordinary to the Ionian islands. In 1859, on Lord Palmerston's return to office, Mr. Gladstone again became a member of the government as chancellor of the exchequer.—Mr. Gladstone married, July 25, 1839, Catharine, the eldest daughter of Sir Stephen Richard Glynn, M. P. for Flintshire, and has a numerous family. In person he is slight and nervous, with a countenance in which a singular sweetness of expression is blended with an eager student look. As a debater he is acknowledged universally to hold the first place in the house of commons, and his reputation as an administrator is almost equally great.—The published works of Mr. Gladstone include "The State in Connection with the Church" (2 vols., 1838), "Church Principles Considered" (1 vol., 1840), "Studies on Homer and the Homeric Age" (8 vols., Oxford, 1858); and he has supervised a translation of Farini's *Stato Romano* (4 vols., London, 1859). In 1851 he published a "Letter to Lord Aberdeen" on the cruelties inflicted on the political prisoners confined in the dungeons of Naples, which produced a universal and very deep impression.

GLADWIN, an E. co. of Mich., intersected by Titibiwassee river; area, 570 sq. m. Its surface is moderately uneven, and its soil consists of a sandy loam. It is not included in the census of 1850, having been recently erected.

GLAGOLITIC, one of the two ancient Slovenic, or less correctly Slavonic, forms of writing. It is derived from the 4th letter, *glagol*, equivalent to our hard *g*, as in *go*, *give*; and is also known as the *Bukvitsa*, from *bukva*, letter, or from the names of the 2d and 3d letters, *buk* and *vida*, or *b* and *v*. Its formation is attributed by some to St. Jerome, and by others to Methodius, the apostle of Pannonia and Great Moravia (about 860). The shape of the 32 letters (of which 27 are also numeral signs) is very grotesque and protean, little resembling the Greek. The Glagolitsa was used in Illyria, Dalmatia, and Bulgaria. The other form of Slovenic writing is the *Kirilitsa*, contrived by Cyrillus, the reputed brother of Methodius, many letters of which are like the Coptic, because they imitate the Greek forms. This consisted originally of 40 letters, and is still in use among the eastern Slavi and the Wallachians. The Russian *azbuka* or *bukvar* (alphabet) is a slight modification of the latter, with 32 letters. These systems have been much extolled by some authors; but, though representing all sounds of the lan-

guages, they are imperfect, inasmuch as they contain single signs for complex sounds, such as *ts, tsh, shih, ye, ya, yu*. The nations that employ these graphic systems belong mostly to the Greek church; while the Catholic Slavi (Poles, Bohemians, Slovacks, Lusaticans, &c.) make use of the Latin or the so called German letters, with some modifications. The most remarkable works in Glagolitic writing are: *Glagolita Olosianus*, by Count Paris Cloz of Trent in the 11th century, edited by Kopitar (Vienna, 1886); *Codez Assemanicus, continens Lectiones Evangelicas, Bibliotheca Vaticana, in Aug. Maiji Scriptorum Veterum Nova Collectione*; *Codez continens Psalmos, cum Expositione S. Athanasii*, &c., at Bologna; all these are in the Bulgarian idiom. *Breviarium* (edited by Brozich, Venice, 1561) is in Serbian.

GLAIRE, JEAN BAPTISTE, a French theologian and orientalist, born in Bordeaux, April 1, 1798. A brilliant pupil of the seminary in his native town, he was sent to Paris, where he entered the St. Sulpice seminary to complete his theological studies, meanwhile studying the Hebrew, Chaldaic, and Syriac languages under the direction of the abbé Garnier; he also attended the lectures of Sylvestre de Sacy on the Persian and the Arabic, and those of Eugène Burnouf on the Sanscrit. Taking holy orders in 1822, he taught Hebrew in his seminary, and was in 1825 appointed to fill the chair of Chanaï de Lanzaç at the Sorbonne. In 1838 he obtained the degree of D.D., and was in 1841 made dean of the faculty of theology. In 1848 he left the chair he formerly occupied to take another, where his special duty was to expound the Holy Scriptures. Two years later he was nominated counsellor of the university and member of the legion of honor. An honorary canon of Bordeaux since 1827, he was in 1851 promoted to the honorary vicarship of that archbishopric. His most important works are: *Lexicon Manuale Hebraicum et Chaldaicum* (8vo., Paris, 1830; new ed., considerably enlarged and improved, 1848); *Principes de grammaire Hébraïque et Chaldaïque* (8vo., Paris, 1832; new ed., 1836 and 1848, with a *Chrestomathie Chaldaïque et Hébraïque*); *La sainte Bible en Latin et en Français*, with notes, explanations, &c. (8 vols. 4to., Paris, 1834); *Torath Mosché, Le Pentateuque*, with a French translation and notes, of which the two first parts only have been published, Genesis and Exodus (2 vols. 8vo., Paris, 1835-'7); *Introduction historique et critique aux livres de l'Ancien et du Nouveau Testament* (6 vols. 12mo., Paris, 1836), an abridgment of which appeared in 1846 (1 vol. 8vo.); *Manuel de l'Hébraïsant*, containing a grammar, a chrestomathy or choice pieces, and a lexicon (12mo., Leipsic, 1856); *Concordances Arabes du Coran*; *Principes de grammaire Arabe* (1857).

GLAMORGANSHIRE, a maritime co. of S. Wales, bounded N. by Caermarthenshire and Brecknockshire, E. by Monmouthshire and the Severn, S. and W. by the Bristol channel; area

660 sq. m.; pop. in 1851, 231,849. The northern portion is mountainous, but the southern is level and fertile. The principal crops are wheat, barley, oats, beans, peas, vetches, and turnips. The horned cattle are of superior quality, and in the mountain districts great numbers of sheep and ponies are reared. Glamorganshire is famous for its coal and iron mines. In the neighborhood of Merthyr-Tydvil the iron works are on a gigantic scale; within a small circuit there are upward of 60 blast furnaces, some of which have more than 4,000 workmen engaged on them. Vast quantities of coal and iron are annually exported from Cardiff. The principal rivers are the Rhymney, the Taff, and the Tawe. The chief towns are Cardiff, the capital, Merthyr-Tydvil, Swansea, and Neath. This county has also some woollen manufactories, and numerous canals and railways. It returns 5 members to parliament—2 for the county, and one each for the boroughs of Cardiff, Merthyr-Tydvil, and Swansea.

GLAND (Lat. *glans*, an acorn), in anatomy, the general name of a variety of organs whose functions are to elaborate the various products of secretion from the blood, to perform certain offices connected with absorption and assimilation, and to assist in the process of preparing and maintaining the circulating fluid in a normal condition. Of the first class of glands the liver and the kidneys are examples, of the second the mesenteric and lymphatic glands, and of the third the spleen. The true secreting glands are of various form, size, and structure, but are all constructed with special reference to the arrangement of the nucleated and epithelial cells and tubes or cavities which enter into their texture; their products are poured forth either on the outer surface of the body, or on some cavity or canal communicating externally, and the cells which effect the separation of their special secretions from the blood are generally in the relation of epithelium cells to the inversions of the skin or mucous membranes that form the greater part of their follicles or tubuli. These cells generally minister to the act of secretion by yielding up their contents by rupture, as in the mammary gland and liver; some of the more liquid excretions, as the sweat and urine, are formed without the destruction of the cells lining the gland tubes, though in most this act is the result of vital processes, a constant development, growth, and destruction of gland cells. The different secretions cannot be explained by any differences of supporting structure, by the amount of blood, or the arrangement of the vessels in the respective glands. Some glands, like the kidneys, discharge their secretions as soon as formed, for the purification of the blood; others, like the testes, store up their products for occasional use; while others, like the salivary and lachrymal glands, constantly secrete a small quantity, which is easily increased by special excitement. The great majority of glands with permanent ducts may be divided into 3 groups, according to the modes

in which the cell-containing tubes are arranged: 1, the simple tubular glands, like the follicles of the stomach and intestines, which seem to be mere depressions in the mucous membrane, elongated gland vesicles lined with secreting cells; 2, the aggregated or conglomerate glands, in which a number of vesicles are grouped into lobules, and these again into lobes joined by loose areolar tissue, like the salivary, mammary, pancreatic, prostate, and lachrymal glands, and also the liver; 3, the convoluted tubular glands, as the kidneys and the testes, ending in dilations, cul-de-sacs, or loops. In all a large extent of secreting surface is packed in a small compass; while one end of the gland and duct opens on a free surface, the opposite end is closed, with no direct communication with blood vessels or other canals. The glands of secretion have been divided into 2 classes, according as their product is excrementitious and to be cast off, or to be used within the system; the former are called more properly excretory glands, and include the liver, kidneys, testes, and prostate, and those which supply the cutaneous and pulmonary transpiration and the peculiar fecal fluids of the lower part of the intestinal canal; the true secretory glands are the gastric, salivary, mammary, sebaceous, mucous, lachrymal, Brunner's, and the pancreas. The kidneys, liver, mammary glands (secreting respectively urine, bile, and milk), and the pancreas will be described under their proper titles; the salivary and gastric glands have been noticed under *Digestion*; the sebaceous, ceruminous, odoriferous, and sudoriparous glands (secreting the oily, waxy, odorous, and perspiratory matters of the surface), will be treated in the article *Skin*; the follicles of Lieberkühn (in the small and large intestine), Brunner's glands in the duodenum, and the solitary glands most numerous in the cæcal region, will be described under *Intestine*; the lachrymal glands are spoken of under *Eye*; the so called glands of Pacchioni and the pineal body or gland are alluded to in the article *Brain*. The air passages of the chest and head, the alimentary canal above the stomach, and the genito-urinary apparatus, are provided with solitary and aggregated glands and follicles for the secretion of their lubricating mucus; the tonsils are glandular masses principally, and there are numerous follicles in the posterior fauces, and in the neighborhood of the epiglottis and entrance to the larynx, whose diseased secretions and ulceration constitute the kind of *folliculitis* popularly called "clergyman's sore throat."—Another system is that of the vascular or ductless glands, which possess all the elements of glandular structure, except the efferent ducts; restoring therefore to the blood whatever they take from it, it is generally admitted that they perform some part in the process of sanguification, probably acting upon such nutrient materials as are taken up directly by the blood vessels without in the first instance passing through the absorbents. These glands are the

spleen on the left side of the abdominal cavity; the thymus gland, a fetal organ in the anterior mediastinum; the thyroid body, on the anterior portion of the neck; and the supra-renal capsules, surmounting the kidneys; these will be described in their alphabetical order. They are composed of vesicles or sacculi, simple and closed, or branched, of a delicate membrane surrounded with a vascular plexus, and filled with an albuminous fluid containing fat granules and nucleated cells. The opinion that these glands serve for the higher organization of the blood materials is supported by the fact that they are especially large and active during fetal life and childhood, when the most abundant supply of nutrient fluids is necessary; they are also believed to be concerned in supplying the germs of cells which are ultimately to become blood corpuscles. They are not essential to life in the adult; the thymus entirely disappears, the thyroid may be completely disorganized, and the spleen be removed (as has been often done in animals), without any apparent ill consequences; the supra-renal capsules seem to preside over the production of the pigment cells, and their morbid condition or atrophy is connected with the peculiar disease known as "bronzed skin."—The last group includes the absorbent glands, the patches of Peyer, the mesenteric, and the lymphatic glands. The lacteals and the fluid they convey have been described under *Absorption* and *Chyle*. Peyer's glands, most numerous toward the ileo-cæcal valve, are intimately connected with the lacteals; whether single or in clusters, they are always in that portion of the intestine which joins the mesentery; they are capsules, containing fatty and albuminous matters, with nuclear particles and cells, all apparently undergoing rapid changes; the exterior and interior of the capsules are freely supplied with blood. In the mesentery are situated the mesenteric glands, which bear the same relation to the lacteals that the absorbent glands do to the lymphatics; each gland is enclosed by a fibrous sheath, which forms by its partitions an internal supporting framework; the intervening alveoli are filled with a grayish pulp, as in Peyer's patches, penetrated by a fine capillary plexus, and in free communication with the afferent and efferent ducts between which they are situated; the number of corpuscles of the chyle is greatly increased by passing through these glands, which perform a most important part in the blood-making or assimilating process. No lacteal or lymphatic reaches the terminal thoracic duct without passing through one or more of these glands. In the lower vertebrates plexuses of lymphatics occupy the places of the glands of birds and mammals. Glands are situated all along the course of the lymphatic vessels, both superficial and deep-seated. Familiar examples are the glands in the groin, the seat of syphilitic and scrofulous abscesses, and often swollen from irritation of any portion of the lower extremity; the axillary glands in the armpit, often requiring surgical interference for enlargements and ab-

scesses; and the glands on the sides of the neck, the seat of frequent suppuration in scrofulous children and adults.

GLANDERS, a contagious and fatal disease, arising in man from the introduction into the system of a specific animal poison from the horse, characterized by glandular swellings and abscesses in various parts of the body, by pustular and gangrenous eruptions and ulcers on the skin and mucous membranes of the air passages, and by a profuse and fetid purulent discharge from the nose. In the horse there are two forms, which have received different names, though they are stages of the same disease; when seated in the lymphatic glands and vessels, it is called farcy, and when in the nasal cavities, glanders; the purulent matters of either of these forms will produce the other, and the former will proceed to the latter if the animal live long enough, though glanders generally arises first. The hard cord-like swellings of the lymphatics and their glands are called farcy buds; these suppurate, and form fistulous ulcers, discharging a thin sanious matter. In glanders in the horse, there is a constant flow from the nostrils, at first thin and watery, afterward thick and opaque, and finally purulent, bloody, and fetid; the vesicles which form on the Schneiderian membrane become foul ulcers, involving even the bones of the nose; the soft parts of the face swell, ulcerate, and become gangrenous, causing speedy death from putrid fever or the slower process of exhausting suppuration. Glanders in man has been called *equinia* by Elliottson, indicating its origin from the horse family, and corresponding in termination to *vaccinia*, or small pox modified by passing through the system of the cow. This disease has been long known in veterinary medicine, but it is less than 40 years since it was ascertained that it could be communicated from horses to man as a specific affection equally fatal to equine and to human life; since then the cases have so multiplied that there cannot be a doubt that the accidental inoculation of glanderous matters from the horse will produce the same disease in man; it has been positively asserted that the glanders may be communicated by infection without actual contact with the morbid products, but this may reasonably be doubted. Acute glanders has a period of incubation varying from 3 to 8 days, when the symptoms attending the action of animal poisons begin to show themselves, such as severe wandering pains, high fever, delirium, profuse and offensive perspiration and discharges; the inoculated part becomes red, swollen, and painful, and the lymphatic vessels and glands inflamed, followed by diffused abscesses in the neighborhood of the large joints, and by symptoms of typhoid fever and great prostration. In a few days a shining livid inflammation invades the face, and the characteristic viscid, offensive, and sanious discharge is poured out from the nostrils; at the same time numerous hard and large pustules appear

on the face; these pustules spread over the neck and body, the nasal discharge is accompanied by gangrene, the abscesses increase in size and number, and death occurs in the low muttering delirium of the putrid fevers. In chronic glanders there is the peculiar nasal discharge, with pain and swelling of the nose and eyes, emaciation, profuse perspiration, abscesses, and gradual exhaustion of the vital powers. In acute farcy the first symptoms are those of inflammation of the lymphatics leading from the wound or abrasion, followed by abscesses, pustular eruptions, and nasal discharge of glanders. In chronic farcy the progress is slower, the abscesses degenerating into foul ulcers, and the disease terminating, perhaps after the lapse of months, in acute glanders, if the patient survive the exhausting suppuration. The pustules commence in the skin or on the mucous membranes, but the unhealthy inflammation soon involves the underlying areolar tissue, forming greater or smaller purulent collections; the foul ulcers of the nasal passages and their connected sinuses commence by a pustular eruption on the mucous surfaces; the ulcers often extend to the pharynx and larynx, and small abscesses are found in the lungs, the consequence of purulent absorption; the veins and lymphatics are usually more or less filled with pus, and always inflamed in the vicinity of the inoculated part. The average duration of this disease is from 15 to 20 days; it sometimes proves fatal in one week, and may be prolonged to the 6th. The glanders was formerly confounded with the malignant pustule, from which it is distinguished by the general symptoms preceding the eruption, by the numerous abscesses, and the peculiar nasal discharge; in ordinary purulent absorption there is not the pustular and gangrenous cutaneous eruption, neither will the inoculated pus reproduce the specific lesions of glanders. The general assemblage of symptoms will also sufficiently distinguish it from malignant small pox, scurvy, and gangrenous typhoid fevers. Glanders in the horse may arise spontaneously when the animal is exposed to insufficient or unwholesome food, foul air, and confinement; but there is no record of these or any other similar causes having produced the disease in man; he always contracts it from the horse or ass by actual contact with the glanderous matter; the miasmata of the disease will often convey a malignant and fatal form of fever to man, but never, as far as is known, the true glanders. The blood of a glandered horse injected into the veins of a healthy one will produce the disease; it appears in from 8 days to a month after inoculation, according to circumstances ill understood. It does not appear that ruminating or carnivorous animals are subject to glanders; it is probable that other solipeds, as the jaghtai, quagga, and zebra, are susceptible to the disease, which seems peculiar to the *equidae*. The prognosis in the acute disease is highly unfavorable, a little less so in the chronic form, though recovery in either case is a rare

exception; of course those having charge of glanderous horses should take the greatest precautions against inoculation of any wound or abrasion, though some constitutions seem proof against even this highly contagious disease. It is produced by the introduction into the blood of man of a specific animal poison, existing in its most intense form in the nasal secretions and purulent discharges of glanderous horses; the disease in the horse and in man is unquestionably the same; the nasal discharge in the latter is less remarkable, and indeed may be absent, because in him, prostrated on his back, the secretions of the nose fall down into the throat, and are spit from the mouth, while in the horse the fetid matters would naturally flow from the nose. If any thing were wanting to complete the chain of evidence, we have it in the fact that the inoculation of the nasal and purulent matters from men affected with glanders has always produced the same disease in the horse and ass. No treatment has been found effectual in this disease; the blood being poisoned from the beginning, the indication is to support the strength by stimulant and antiseptic tonics, especially wine, ammonia, and ether; all depletion is out of the question; swollen glands may be extirpated, abscesses opened as soon as formed, and the nasal cavities injected with creosote and chlorinated solutions; nervous irritation may be quieted by narcotics, and the foul odor annihilated by chlorine and other disinfectants. Creosote, according to Elliotson, is the best remedy; iodide of potash and iodine have been successfully employed in acute farcy.—For fuller details on glanders and farcy, the reader may consult Elliotson in vols. xiii., xviii., and xix. of the "London Medico-Chirurgical Transactions;" Rayer, in the *Mémoires de l'Académie royale de médecine* (1837); Dr. Burgess, in his translation of Cazenave on "Diseases of the Skin" (London, 1842); and occasional cases in the domestic and foreign medical journals.

GLANVIL, or GLANVILLE, RANULF DE, chief justiciary of England in the reign of Henry II., and supposed author of one of the oldest treatises on the laws of England, died in 1190. He was of Norman descent, signalized his valor under Henry II. in repelling the invasion of England by William of Scotland, accompanied Richard I. on the crusade, and perished at the siege of Acre. The work ascribed to him is entitled *Tractatus de Legibus Consuetudinibus Regni Angliæ, Tempore Regis Henrici Secundi*, was first published in London in 1554, ranks with those of Britton, Bracton, and Fleta, and is relied upon as authority by the principal modern authors. Some of the manuscripts state only that it was written in his time, without ascribing it to him. The best edition is that by John Wilmot (1780). The only English translation is by John Beames (1812).

GLANVILLE, JOSEPH, an English divine and philosopher, born in Plymouth in 1686, died in Bath, Nov. 4, 1680. He was educated at Oxford, became a priest, and was made rector of

the abbey church, Bath, in 1666. He became chaplain in ordinary to the king, and in 1678 was appointed a prebendary of Worcester cathedral. He is distinguished as an opponent of Aristotelianism, as a believer in witchcraft, and as the first writer in England who presented philosophical scepticism in a systematic form. His first work, entitled the "Vanity of Dogmatizing," was published in London in 1661, and a 2d and enlarged edition of it appeared in 1665, under the title of "Scep sis Scientifica, or Confessed Ignorance the way to Science," with a dedication to the newly founded royal society, which body at once elected him a fellow. The design of the book is to show the necessary ignorance of man and the impotence of reason in respect to the most important objects of knowledge, and especially to censure the verbal and captious character of the prevalent peripatetic philosophy, with its meaningless terms and definitions. In his treatment of the question of causation he prepared the way for Hume. His style is animated and elegant. He made another attack on the ancient philosophy in his "Plus Ultra, or the Progress and Advancement of Knowledge since the Days of Aristotle" (1668), in which he exalted Bacon and Boyle and the inductive method. Notwithstanding his scepticism, he credited the stories of sorcery and witchcraft. The account of a drum that was heard every night in a house in Wiltshire, which furnished Addison the idea of his comedy of the "Drummer," appears to have been the occasion of Glanvill's "Philosophical Considerations concerning the Existence of Sorcerers and Sorcery" (1666), the convictions expressed in which are repeated in his *Sadducismus Triumphans*, published posthumously (1681), with an account of his life and writings by Dr. Henry More. Among his other works are *Lux Orientalis* (1662), in which he treats of the preexistence of souls, following the views of Henry More; "Essays on Several Important Subjects in Philosophy and Religion" (1676); an "Essay on Preaching" (1678); and a volume of sermons, edited by Dr. Horneck (1681).

GLARUS, or GLARIS, one of the smallest of the Swiss cantons, bounded N. and E. by St. Gall, S. by the Grisons, and W. by Uri and Schwytz; area, 280 sq. m.; pop. in 1850, 80,218, of whom 26,281 were Protestants and 8,932 Catholics. The principal of the mountain chains which occupy almost its entire surface extends from the Hausstock to the Scheibe, and has an average height of 8,000 feet, but there are many separate peaks of much greater elevation. The Doedi or Tödi, 11,887 feet high, in the S. part, is the loftiest mountain in E. Switzerland. Traversing the canton from N. to S., and extending from the land between the lakes of Zürich and Wallenstadt to Mts. Doedi and Scheerhorn, is a large valley through which flows the river Linth, and opening into this are 3 or 4 minor valleys, each the basin of a river of its own name which empties into the Linth. The chief of these are the Sernft and

the Klön. Only their deepest and most sheltered parts are habitable throughout the year, and even in such places snow often remains until the middle of April. There are several lakes, shut in by the wild and romantic scenery characteristic of this Alpine region, but none remarkable for size. The lake of Wallenstad forms about 8 miles of its northern boundary. Not more than $\frac{1}{4}$ of the surface is susceptible of tillage. The most fertile land lies in the valley of the Linth, where grain and fruit, particularly cherries, are cultivated with success. The accessible parts of the mountains are occupied by pastures. From these snow-capped hills, the cradles of vast glaciers, innumerable torrents pour into the valleys during the spring and summer, and often cause fearful devastation. With the exception of marble, slate, and gypsum, there are no minerals of much importance. Small quantities of coal are found, and there are ancient mines, now almost exhausted, of silver, copper, and iron. The principal kinds of timber are pine, beech, ash, maple, and chestnut. The flora, ranging from an altitude of 1,500 feet above sea level to the highest point of vegetation, is varied and rich. The chief species of game are the chamois, fox, hare, marmot, and badger. The pastures feed about 10,000 horned cattle, 12,000 sheep, and 6,000 goats. One of the most important manufactures is that of the well-known *schabzieger*, or "green cheese," made of the milk of cows and goats, mixed with churned milk, and colored and flavored with the blue pansy, locally called *klee*. The other manufactures comprise cotton, woollen, linen, and silk goods, prints, muslins, writing slates, and many articles in wood. An active trade is carried on with Germany and Italy, transportation being effected through a number of mountain passes, and by means of 2 canals which connect the Linth with the lakes of Wallenstadt and Zürich. Glarus, which occupies the 7th place in the Swiss confederation, enjoys a singularly democratic form of government, the supreme power residing in a general assembly of all the males over 16 years of age, who meet annually to elect magistrates and accept or reject the laws proposed by the executive council of 80 members. Taxation is very light, crimes are few, and education is almost universal. The canton contributes 8,615 francs to the federal treasury, and 482 men to the army. The chief towns are Glarus, Mollis, Enneda, and Schwanden.—The name Glarus is supposed to be a corruption of St. Hilarius, in whose honor a church was built in this canton about 490 by an Irish monk called Fridolin, the founder of the convent of Seckingen on the Rhine. The upper part of the valley became the property of this convent, while the lower was dependent upon the nunnery of Schännis. It was afterward subject to bailiffs nominated by the house of Hapsburg, to escape from whose tyranny the inhabitants joined the Helvetic confederation in 1852, and in 1888 secured their independence by the famous victory of Näfels.

Zwingli was curate of Glarus from 1506 to 1516. The introduction of Protestantism gave rise to many disturbances.—GLARUS, capital of this canton, is a thriving manufacturing town, situated in a secluded Alpine valley at the foot of Mts. Glarnisch and Schilt, on the left bank of the Linth, here crossed by 2 bridges; pop. 4,500. It contains a Gothic church, used by both Catholics and Protestants, a free school for 700 children, a new government house, an old town house, and a printing office. The streets are crooked and narrow, and the houses are fantastically painted. Cottons, woollens, muslins, and hardware are the principal manufactures. In mid-winter the town is almost continually in the shadow of the mountains, the sun being visible only during 4 hours of the day.

GLASGOW, the chief commercial and manufacturing city of Scotland, situated on both banks of the river Clyde, 20 m. from the sea, in the county of Lanark, lat. 55° 51' 32" N., long. 4° 17' 54" W.; distant from Edinburgh, W. by S., 43 m. by road and 48 by rail, and from London, N. E., 404 m.; pop. in 1851, including the suburbs, 844,986, of whom 162,933 were males, and 182,053 females. Following the ratio of increase of the preceding 10 years, the population would now (1859) be 401,516. Glasgow is $\frac{1}{4}$ m. in length, and 2 m. in width. The city proper stands wholly on the N. bank of the Clyde, with the burgh of Gorbals and districts of Hutcheson and Kingston S. of the river, Anderston W., the burgh of Blytheswood and Port Dundas W. and N., and the burgh of Calton E., so blended together as to form but one city, under a common municipality and police. Glasgow is a royal, municipal, and parliamentary borough, governed by a lord provost (mayor), 8 bailies (aldermen), and 39 councillors, beside the dean of guild and the deacon convener of the trades, who are members of council *ex officio*. Two of the council exercise a species of admiralty jurisdiction over the river and frith of Clyde. About 5,000 prisoners pass through the gaols annually. The police force consists of 627 men, and the total cost of the police in 1854, including lighting and cleansing, was £64,726. The burgh returns 2 members to the house of commons. The average annual mortality is 1 in 38, and of children under 5 years of age 1 in 8. The climate is temperate, but humid; the mean annual fall of rain is 32 inches, and the mean range of temperature 49° to 75°. Glasgow has been lighted with gas since 1817. It has a large supply of water, of indifferent quality, furnished from the Clyde by a water company, and within a few years an arrangement has been made for investing the corporation with power to convey water from Loch Katrine. The ground plan of the city is tolerably regular. A principal street runs E. and W. parallel to the river, on the N. side, for a distance of $\frac{1}{4}$ m., under the several names of Argyle street, Trongate, and Gallowgate. Parallel to this are many fine streets, as Ingram, St. Vincent, George, &c., these being intersected

by other streets running N. and S., of which the principal and most ancient is the High street and Saltmarket. The Green is a well kept park of 140 acres, lying along the N. side of the Clyde, at the E. end of the city. This is emphatically the people's park, where the various peculiarities of Glasgow life and conversation may be studied to advantage. Kelvin grove, written of by Burns, has been purchased by the city, and is being laid out as the West End park from designs by Sir Joseph Paxton. A botanical garden of 40 acres lies about 1 m. N. W. from the city, and is mostly used in connection with the botanical classes of the university, but is open to the public, at stated periods, on payment of one penny. There are many fine buildings. The cathedral or High church is the best specimen remaining in Scotland of the old ecclesiastical architecture. It stands conspicuously on high ground in the N. E. section of the city. It was commenced in 1133, but was not completed for 3 centuries. It is in the early English style, 320 feet in internal length, and 68 in breadth; the height of the choir is 90 feet, and of the nave 85 feet. A square tower rises from the centre of the building, surmounted by an octagonal spire 225 feet in height from the floor of the choir, which itself is 104 feet above the level of the Clyde. Many of its windows are of exquisite workmanship. Under the cathedral is an extensive crypt formerly used as a chapel. The whole number of churches in 1851 was 143, distributed as follows among the various denominations: Baptist, 7; Episcopalian, 5; Established church, 25; Free church, 30; Independent, 11; Roman Catholic, 7; United Presbyterian, 23; other denominations, 85. S. W. of the cathedral stood the bishop's castle, erected in 1430, but the ruins were removed in 1789 to make way for the infirmary, a fine edifice, wholly supported by voluntary contributions. The royal exchange, the handsomest building in the city, is in the florid Corinthian style, with a colonnade. Its news room is 122 feet long by 60 broad, with an ornamented roof supported by 18 pillars. Among the other edifices of a public nature are the new city and county buildings, containing all the municipal offices, as also the merchants' hall; the court house, at the W. end of the Green, with a frontage of 215 feet, in the Doric style, &c. Five bridges, all of modern construction, cross the Clyde. The Victoria bridge, 467 feet long and 60 feet wide, with 5 arches of freestone cased with granite, is one of the finest structures in Europe. Glasgow bridge, designed by Telford, with 7 arches, is 560 feet long and 60 feet wide. Glasgow contains several public monuments, among the chief of which are an equestrian statue of William III., in the Trongate; an obelisk to Nelson, in the green; a bronze statue by Flaxman of Sir John Moore, a statue by Chantrey of James Watt, and one of Sir Walter Scott on a Doric column 100 feet high, all in George square; a statue of Pitt by Chantrey, in the town hall, which also contains some historical portraits; a statue

of Sir Robert Peel; an equestrian statue of the duke of Wellington, in front of the royal exchange, by Marochetti; a statue of Queen Victoria, to commemorate her visit to the city in 1849, also by Marochetti; and one of John Knox on an obelisk in the necropolis. The commercial institutions of Glasgow are a chamber of commerce, instituted in 1788; the royal exchange and Lloyd's room, with 2,000 subscribers; E. and W. India associations, &c.; with 11 joint-stock banks and branches, and 1 savings bank. The educational institutions of Glasgow are of the highest rank. The university, founded under a bull of Pope Nicholas V. in 1451, is annually attended by 1,000 students. They are all non-resident, and pay only the fees for tuition, boarding where they please. Sixty foundations, or bursaries, in value generally from £5 to £25, a few being worth £40, and one £50, per annum, are distributed among the students, and are held for 4 or 6 years and applied in payment of tuition. In addition to these are 10 of £120 per annum, and 4 of £20 for 10 years to scholars of the Glasgow university studying at Baliol college, Oxford. There is but one session annually, from the last Wednesday of October to May 1, and the academic course extends over 4 years. Whatever other studies they pursue, students are required to attend Greek the 1st year, having previously a knowledge of Latin, logic the 2d, moral philosophy the 3d, and natural philosophy the 4th. The academic body of the university consists at present of the lord chancellor, the lord rector, the dean of faculty, the principal and vice-chancellor, 22 professors, and 1 lecturer. The office of chancellor, formerly a royal appointment, is now an honorary election for life. The university buildings are in the Elizabethan style, and have a front of 305 feet on High street, with a depth of 282 feet, forming 4 quadrangular courts, 3 stories high, with turrets, and having a spire 153 feet high; its lightning rod was erected in 1772 under the auspices of Dr. Franklin. The university contains a library of 60,000 vols. Immediately behind the college is the Hunterian museum, containing the library, coins, and anatomical collection bequeathed by Dr. William Hunter to the university. The collection is valued at £180,000. The Andersonian university is an institution on the plan of a college for the working classes. It was founded by Dr. Anderson, professor of natural philosophy in the Glasgow university, and brings within reach of operatives the study, under able teachers, of the physical sciences, medicine, literature, and the arts. It had 1,685 pupils in 1854-'5. A mechanics' institute and government school of design are also in successful operation. The high school, or grammar school, is believed to be older than the university, to which it is preparatory. Glasgow has 2 normal training schools, belonging respectively to the Established church and Free church of Scotland. The philosophical, literary, and various antiquarian societies have each their collections of

special libraries. There are several publishing houses in the city, but that business is mostly absorbed by Edinburgh. The daily and weekly newspaper press is conducted with ability. The charitable institutions are very numerous, comprising asylums for the aged and destitute, for the deaf, dumb, blind, and insane, hospitals, charity schools, and various benevolent associations. Hutcheson's hospital distributes alms to about 500 persons annually, most of whom are women, and educates and clothes between 150 and 200 boys.—Glasgow is most favorably situated both for manufacture and commerce, and beside its ocean navigation is the centre of a system of canals and railways. The Forth and Clyde canal, 85 m. long, having its Glasgow terminus at Port Dundas, unites the 2 seas E. and W. of Scotland, with 10 feet of water; the Monkland canal, 12 m. long and 6 feet deep, connects with the coal and iron mines; and the Paisley and Johnstone canal unites the city with the 2 towns from which it has its name. The railways are the Glasgow and Paisley; Monkland; Glasgow, Paisley, and Greenock; Edinburgh and Glasgow; Glasgow and south-western; and the Caledonian. There are steamship lines to New York, Liverpool, Belfast, *via* the Clyde, Dublin, Bristol, Waterford, Cork, Londonderry, Stranraer, and Portrush, together with the lines of 18 companies to all parts of the Scottish highlands and islands. The Clyde has a course of 115 miles, but is of no value as a water-course above Glasgow. The improvement of the river navigation has been intimately connected with the growth of the city. Its channel has been almost made by artificial means since 1555. In 1662 the magistrates purchased a port 16 m. down the river, and built a harbor called Port Glasgow. In 1688 a small wharf was built at the Broomielaw, but for the next 100 years no vessel drawing more than 6 feet of water could come up. The depth of water in 1855 was 19 feet. The wharves extend over 2 m. in length, with sheds and all other needful accommodation, in immediate connection with the various railways. The harbor has 48 acres of water surface. The river for 7 m. below the city has been widened and embanked with stone. Till the American war the Glasgow merchants enjoyed almost the monopoly of importing tobacco. After that event they turned their attention to the West Indian trade. Their traffic with the East Indies dates from 1816. Their timber trade with the British N. A. provinces is very extensive, and an important business is now done in Australian emigration and supply. The establishment of steamships to New York has also enabled exporters to fill orders direct, which formerly flowed through other ports. The principal articles of export to the United States are iron, coal, cotton thread, bleaching powders, sewed muslins, Turkey-red cambrics, red and yellow prussiates, jaconets, shawls, tobacco pipes, cast-iron water and gas pipes. The following table exhibits the commerce of the port in 1856:

Vessels.	Entered.		Cleared.	
	Number.	Tonnage.	Number.	Tonnage.
Steam.....	1,656	406,275	1,696	416,273
Sailing.....	1,581	226,428	2,344	274,881
Total.....	3,237	632,708	4,940	791,153

Of these totals the coasting trade employed 1,656 steam vessels (tonnage 385,544) and 112 sailing vessels (tonnage 99,981) inward bound, and 1,612 steam vessels (tonnage 384,622) and 2,378 sailing vessels (tonnage 151,478) outward bound. The entries and clearances from and to the countries chiefly interested in the foreign trade of Glasgow were as follows:

Countries.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
United States.....	92	59,102	101	65,613
Italian States.....	64	11,981	43	8,410
France.....	54	7,635	800	28,951
Portugal and the Azores.	40	5,184	67	8,000
Egypt.....	35	9,296
Spain.....	29	2,966	28	4,474
Russia.....	20	3,710	8	1,410
Central and S. America.	18	6,846	46	13,991
Germany.....	18	1,848	16	1,627

In the same year Glasgow owned 413 sailing vessels of 150,621 tons, and 145 steamships of 53,039 tons; total 558 ships, with an aggregate tonnage of 203,660. The value of exports from Glasgow in 1854 was £4,905,557, and the amount of customs dues collected on imports £666,818.—The manufactures of Glasgow are cotton goods, woollens, silks, shawls, carpets, glass and pottery, chemicals, iron, and machinery of all kinds, particularly marine steam engines. It has beside distilleries, breweries, dye works, bleach fields, paper mills, and an endless variety of fancy hand-loom fabrics. In and near the city in 1854 there were 95 cotton factories employing 22,000 hands, 7 woollen works with 700 hands, 4 silk factories with 700 hands, 4 flax with 1,300 hands, and 11 calico print-works with 3,000 hands; in all, 121 manufactories with 27,700 persons engaged in the place in the production of textile fabrics, together with the population of the weaving villages for a large circuit around the city, and the factories at Blantyre, Lanark, Rothesay, &c., which are properly included in Glasgow industry. In 1856 the number of spindles employed in cotton spinning was about 1,800,000, consuming annually 120,000 bales of cotton, and supplying 27,000 power looms, which produced daily 670,000 yards of cloth. Embroidery and the manufacture of sewed muslin give employment to a large number of females of the surrounding counties. Glasgow has long been noted for its Turkey-red dyes. The dye works, of all colors, employ 1,000 hands. The iron manufactures are equally important with the textile. Situated in the immediate vicinity of the mineral district, Glasgow has every facility for competing in this branch of production with the most favored localities. The introduction of the hot blast in the process of smelting increased the number of furnaces from 16 in 1830 to 102 in

1854, producing, in the district including Lanark and Ayr, 717,600 tons of pig iron. Five of the 6 forges of malleable iron in Scotland are near Glasgow, and the 6 produce annually 123,400 tons. The district consumes annually 2,500,000 tons of coal. In 1854, the value of the coal and iron industries was £4,872,866, employing 38,908 persons. The St. Rollox chemical works employ 1,000 workmen in the manufacture of soda, bleaching powder, sulphuric acid, &c. There are other chemical factories in which the production of nitric and muriatic acids, chemicals of lead and iron, iodine, alum, potash, cudbear, naphtha, and bituminous oils is carried on. Since the increase of steam navigation the building of steamships and construction of engines has become a large source of industry on the Clyde. This occupation began to develop itself in 1821, and has continued to increase since.—Glasgow has but little history apart from the general history of the country. The Romans had a station on the Clyde in the locality of the city, and Antoninus's wall commenced a few miles W. of it. Local tradition assigns the foundation of Glasgow to St. Kentigern, afterward its first bishop, A.D. 539. William the Lion made it a burgh by royal charter, between the years 1175 and 1178. In 1800 a battle between the Scots under Wallace and the English under Percy was fought in the High street, when Percy was defeated and slain. In 1850, '80, and '81, Glasgow was visited by the plague. About 1543 the regent Arran besieged the earl of Lennox in the bishop's castle, obtained it upon promise of terms, and put the garrison to the sword. The same leaders soon afterward fought a battle at the Butts in the E. part of the city, where the regent gained the victory and plundered the city. In 1560 reformed superintendents superseded Catholic bishops. In 1638 the famous assembly of the Presbyterian church was held, when episcopacy was abjured. For several years thereafter the city was a prey to both parties in the civil wars. Fire, plague, plunder, and famine desolated the place. On June 4, 1690, a charter of William and Mary conferred on the townsmen the right of electing their own magistrates. Glasgow was strongly dissatisfied with the union of Scotland and England, but in 1715 and again in 1745 sided with the house of Hanover and raised a force against the Stuarts, for which the pretender's army on the retreat from Derby levied contributions and threatened to burn it. On the breaking out of the American war Glasgow raised a regiment of 1,000 men, and fitted out 14 privateers carrying 14 to 22 guns each, with an aggregate force of 1,000 men. In 1820 the public peace was disturbed by radical political riots, and in 1848 similar demonstrations were made by the char-
 lists.

GLASS (*Sax. glas*). In chemistry any product of fusion having the peculiar lustre known as vitreous, hard and brittle, whether transparent or not, is called glass. In common use the term expresses the transparent product de-

rived from the fusion of silica with an alkali to which lime or a metallic oxide is added. No material invented by man is to be compared with glass in the service it has rendered. To its aid, applied in a thousand different forms, the sciences, particularly chemistry and astronomy, are essentially indebted for their advancement. It has served alike to bring within the ken of man solar systems too remote for unassisted vision to detect, and to open new worlds of living creatures too minute for their forms to imprint a sensible image upon the delicate mechanism of the eye. Thus has it extended and magnified our conceptions of the universe, and of the power of Him who created it. In every direction we find it in homelier ways applied to add to the physical comforts of man. In his habitations it is used to admit the light of day, while it serves as a screen from the wind and rain and cold. As a mirror it is made to throw back the rays that fall upon it; and perfectly reflect the images of objects, while through its transparent sheets every ray is transmitted; and in the vessels of the laboratory the processes going on in their interior are made sensible to the eye. The purity of its material causes the presence of foreign substances to be instantly detected, and it is consequently the most cleanly substance, and especially suited for vessels for holding and keeping liquids. It resists the action of nearly all the powerful chemical reagents; and but for this substance many of them would never have been known, nor could they now be made and kept.—Nothing is known with certainty respecting the early history of this invention. The fact that glass beads or other ornaments of the same material, imitating precious gems in color and beauty, have been found with mummies more than 3,000 years old, carries back the manufacture in Egypt to a very remote time. At Thebes a bead of material similar to crown glass has been found with the name of a monarch inscribed upon it who lived 1,500 years B. C.; and hieroglyphics, that must be as old as the sojourn of the Israelites in Egypt, represent glass blowers at work much after the fashion of the present day. The passage in Job xxviii. 17 is sometimes referred to as an allusion to this material, but when citing the onyx and the sapphire, the term "crystal" is very likely to have been applied to quartz or amethysts, of which cups were in those days made. In the ruins of Nineveh glass lenses, vases, bottles, &c., have been found; but there is no indication of the use of glass for windows. It is not unlikely that the substance was known long previous to the time when it was produced in beads and lenses and blown into useful shapes; for in extracting the metals of the ancient brass from their ores, and in baking bricks and articles of pottery, the workmen must often have drawn out the glassy cinders into strings, and observed the vitreous glazing produced when the clay was mixed with ashes. The lavas of

volcanoes, too, often presented to them rude forms of glass, exhibiting its plasticity, and the various colors of these artificial and natural products often no doubt suggested the possibility of imitating successfully the precious stones—those true and perfect natural glasses. From such hints the ancient Egyptians probably derived their first knowledge of glass; and profiting by them, they soon reached a high degree of excellence in the manufacture. From them the Phœnicians are supposed to have received the art, little credit being due to the tale of Pliny that it was the invention of some merchants of their nation, who observed the sand upon the beach melted by the fire and forming glass in contact with some lumps of soda. A stronger heat than could be obtained from an open fire would be required to effect this result. Nor is much more credit to be attached to his accounts respecting the production of a glass of malleable character, which when thrown upon the ground was merely indented, and could be restored to shape with a hammer, as if it were brass. Some metallic salts, as chloride of silver, possess ductility at the same time with a glassy appearance, and of one of them the articles referred to may perhaps have been made; but all modern experience is opposed to the possibility of malleability existing in a vitrified body. At Sidon and Alexandria glass works were in operation in the time of Strabo and Pliny; according to Theophrastus, the art was practised 370 years B. C., and the processes of cutting or grinding, of gilding and coloring, were then in use. Articles of exquisite workmanship were produced, but of great cost, and known only as luxuries. Vases and cups, some enamelled and beautifully cut and wrought with raised figures, and some remarkable for the brilliancy of their colors, were furnished to the Romans; and it is said that the tribute from Egypt was required by the emperor Aurelian to be paid in articles of glass. Among the most celebrated of the ancient works in glass is the Barberini or Portland vase, found in the tomb of Alexander Severus, who died A. D. 235. It is of a deep blue color, with raised figures in a delicate white enamel. The manufacture of glass was introduced into Rome in the time of Cicero; and in the 3d century articles of the material were in common use. Utensils of it have been found in Herculaneum, and in one or two instances it has been met with in windows in Pompeii. This, however, is not at the present day a very important use for glass in warm climates; and the Romans, moreover, possessed an excellent substitute for it in sheets of mica, which were in use where a protection of this sort was required. Colored window glass is known to have been used in churches in the 8th century; but for private houses glass long continued to be a rarity, and in England in the 12th century houses provided with glass windows were regarded as magnificent. In the time of the crusades the manufacture of glass was brought from

the East and established at Murano, one of the islands adjacent to Venice. Here it was long successfully prosecuted, being sustained by the fostering care of the government, and its workmen being invested with extraordinary privileges. Glass mirrors were probably first made here, and they became famous all over Europe, gradually taking the place of the mirrors of polished metal which were before in use. Many of the ornamental objects they produced were exceedingly ingenious, and are reproduced and admired even at this day. Such are the glass beads and the Venetian balls lately introduced for paper weights, made by combining together colored pieces of waste filigree glass to imitate the forms of flowers, &c., and introducing these into globes of transparent glass, which are made to collapse upon the designs by the glass blower drawing in his breath, and thus exhausting the air from the globe. The lens form of the outer covering increases the effect by magnifying the object within. The filigree work is produced by glass rods of different colors, which are melted to the outside of lumps of glass when partially shaped into decanters or other vessels. The Venetian frosted glass is an old invention, recently rediscovered by Mr. Pellatt. It is made by dipping the hot glass before blowing into cold water and instantly taking it out, softening it by heat and blowing before the cracks are melted in. The Bohemians next acquired reputation in this art; and owing to the purity of the materials found in abundance in their country, as well as to their skill, their wares still continue famous. The French, perceiving the importance of the business, early imitated the example of the Venetians, and gave extraordinary encouragement to any of the nobility who would prosecute the manufacture. In 1684 attempts were made to produce mirrors from blown glass, as was practised so successfully by the Venetians; but about the year 1666 it was found necessary to procure workmen from Venice. Works were then erected at Tourlaville near Cherbourg, which was selected from the resemblance of the locality to that of the works at Murano. In 1688 Abraham Thevart introduced in Paris the method of making large plates by casting the glass instead of blowing; he thus produced heavy plates measuring 84 inches by 50, while those previously made had barely reached in length the smaller figure named, and were necessarily thin. New works were then established at St. Gobain (in the department of Aisne); and the two companies afterward united their interests. In the 18th century the business became very successful, and has continued so to the present time, the products of the establishment ranking among the first in quality in the world.—The manufacture of window glass, according to an old builder's contract, brought to light by Horace Walpole, and copied into his "Anecdotes of Painting," was conducted in England as early as the year 1489; but a decided preference was given to that "from beyond the seas." It was

commenced in London in 1557; and soon afterward flint glass also was made there. The production of plate glass was undertaken in 1670 at Lambeth by the duke of Buckingham, who imported Venetian workmen. The government encouraged the enterprise by a bounty upon the glass intended for exportation; and under this protection, also extended to the different branches of the manufacture, by which the cost was reduced from 25 to 50 per cent., many other glass factories sprung up in different parts of the kingdom; but their prosperity and the progress of the art were afterward greatly checked by the excise duties imposed, and the surveillance of crown officers over all the operations of the works. The bounties and the duties, with their annoying restrictions, were annulled in 1845, when the suddenly increased demand for home consumption brought into existence many more establishments. In 1847 there were in all 24 window glass factories in Great Britain. In 1868 the number was reduced to 8. The capacity of their production is, however, immense, as is shown by the fact that the firm of Chance and co. executed the large order in sheet glass for the crystal palace in 1851 without materially affecting their ability to fill their general orders. The British exports of glass in 1844 amounted to £26,694 in value; in 1855 they exceeded £500,000. The quality of their crown glass is unrivalled.—Belgium is said to be the greatest glass-producing country in the world. In 1854, as stated by Mr. Hartley of Sunderland, the annual production of sheet glass had amounted to 50,000,000 square feet, or 22,800 tons, which was one fourth more than was made in England of both crown and sheet glass. Of this, 85 per cent. was exported, 6 per cent. being sent to England. Of the English production, 85 per cent. was at that time retained for home consumption.—Glass appears to have been one of the earliest branches of manufacture introduced into the United States; but to what extent it was carried on in early times is unknown. In Salmon's "Modern History" (London, 1746), vol. iii., p. 440, mention is made of glass works which were commenced at Jamestown, Va., and the completion of which was interrupted by the Indian massacre of March 22, 1622; and in Howe's "Historical Collections of Virginia," p. 39, is a quotation from "Smith, book iv. p. 18," in which, under date of 1615, it is said that "for a long time the labor of the colony had been misdirected in the manufacture of ashes, soap, glass, and tar, in which they could by no means compete with Sweden and Russia." But the first glass factory in the United States of which we have a precise account was built by Mr. Robert Hewes of Boston, Mass., in the town of Temple, N. H., in 1780. From information obtained by Mr. H. A. Blood, the historian of that town, it appears that the works were located there on account of the cheapness of fuel and labor. The building, of which the ruins are still to be seen, was 65 feet square, and the glass blowers, 33 in number, were German (Hessians and Wal-

deckers) deserters from the British army. In the winter of 1780-'81, in consequence of the carelessness of a drunken furnaceman, the works took fire and were destroyed. Some of the manufactured articles, of a greenish color, are still preserved. A large circular plate, the product of the first operations, was presented by Mr. Hewes to Harvard university. To encourage the rebuilding of the works, the state of New Hampshire, on the petition of Mr. Hewes, authorized him, by act of the general court of March 30, 1781, to issue lottery tickets, and by their sale raise the required capital. The attempt, however, was not successful. From an allusion to this subject by Washington in his diary (1789) it would appear that glass was made at that time in New Haven. In 1800 an unsuccessful attempt was made to establish the business in Boston. In 1808 a German named Lint took charge of the Boston works, and the state of Massachusetts agreed to pay the proprietor a bounty on every table of window glass made. Since that time the works have prospered, and many new enterprises have been started, but the greater number of these have been abandoned. The most important flint glass works now in operation are 3 factories in S. Boston, 2 in E. Cambridge, and one at Sandwich, Mass., 2 in Brooklyn, N. Y. (one of plate glass commenced in 1855, but now discontinued), one in Jersey City, and 2 in Philadelphia. In the southern part of New Jersey are the most extensive works producing window glass, and about Pittsburg, Penn., and the river towns below, and also in central New York, the manufacture is carried on in numerous factories. The first plate glass manufactory was established at Oheshire, Berkshire co., Mass., about 1853. The company afterward removed its works to Lenox, in the same county, and is known as the "Lenox Rough Plate Glass Co." It is the only establishment now in operation devoted to this branch. Henry R. Schoolcraft was engaged in his youth in the manufacture of glass at Oheshire, and in 1817 published a treatise entitled "Vitreology," designed to exhibit the application of chemistry to this art.—Glass is a chemical compound of variable ingredients, different substances of similar character replacing each other to produce its varieties. Silicio acid or silica is its principal element, which combines with the potash, soda, oxide of lead, lime, alumina, and other substances that may be added, to produce silicates of these bases. By the manufacturer the bases are classed as fluxes. Boracic acid may take the place of silicio acid to produce vitreous borates or glass. The proportions of the bases named admitting in their use of indefinite variations, a wide scope is given for the exercise of the skill of the manufacturer in producing any particular quality of glass. The metallic oxides also afford him abundant resources for imparting any desired hue to his product, according as these are judiciously selected and introduced. The important requisite in all the varieties of glass is a fusible compound, which solidifies on

cooling into a transparent mass, without assuming a crystalline structure. Such a substance is a product of the process of reducing metallic ores. It results from the earthy matters of the ores and fluxes being of the composition and proportions fitted to melt together into a fluid cinder, leaving the metal, deoxidized by the carbon of the fuel, free from foreign admixture, and in a condition to drop readily through the glassy fluid. The more perfect a glass is thus obtained the more successful is the operation. But the glass is not the ultimate end of the process, and is too variable and uncertain in quality to be converted to useful purposes. The compounds produced by the glass manufacturer range from the most fusible combinations of one part of silica with 2 or 3 of soda or potash, which melt at a cherry red heat and dissolve in cold water, to the hard and refractory silicates of lime and alumina, some of which, as that represented by the formula $Al_2O_3, 8SiO_2$, require the powerful heat of a furnace to soften them. Potash especially increases the fusibility of glass; the oxides of lead and of zinc, and to some extent barytes, produce a similar effect, while they also add to its softness, its lustre, its specific gravity, and its power of refracting light, and do not interfere with its perfect freedom from color, unless the lead be used in excess, when it gives a yellowish tinge. Iron, in the state of the silicate of the protoxide, imparts a dark green color; but by the addition of a small quantity of bin-oxide of manganese (MnO_2) the color disappears, as the protoxide is converted into the sesquioxide (Mn_2O_3), and the manganese, losing one atom of oxygen, becomes MnO . But if so much bin-oxide has been added that the sesquioxide of this metal is produced, this communicates an amethystine color to the glass. Other metallic oxides, as those of uranium, copper, silver, and gold, are also employed to

give intense colors. Without reference, however, to substances used for imparting or removing colors, or those which may be present by reason of the impurities of the materials employed, as magnesia, alumina, and oxide of iron, the essential materials of the ordinary kinds of glass may be regarded as silica and boracic acid, the alkalies, lime, and oxide of lead. The varieties of glass running into each other, their classification is necessarily somewhat arbitrary. Tomlinson makes this simple division: "1. Silicate of potash and oxide of lead. Examples: flint, crystal, and strass. Flint contains more lead than crystal, and strass more than flint. 2. Silicate of soda and lime; or, silicate of potash, soda, and lime. Examples: common window, English crown, and plate. 3. Silicate of potash and lime. Examples: foreign crown, refractory Bohemian glass. 4. Silicates of soda, lime, alumina, and oxide of iron. Example: coarse green wine bottle glass." The arrangement of Dr. Knapp is as follows: 1. Bottle glass, including the varieties worked into hollow vessels and tubes, as common bottles, glass for medicinal bottles, white bottle glass for vials, tumblers, tubes, &c. The dark-colored varieties are distinguished for their large proportion of oxide of iron and alumina, and none contain oxide of lead. The white bottle glass contains silica, soda or potash, and lime. 2. Window glass, including English crown and cylinder or sheet glass; this is a silicate of potash or soda, lime, and alumina. 3. Plate glass, differing from the preceding only by the greater purity and freedom from color of the materials. 4. Flint glass, used for grinding, &c., composed of silica, potash, and oxide of lead. 5. Crystal, for optical purposes and table ware, consisting of silica or boracic acid, potash, and more lead than the preceding. 6. Strass, the paste used for imitations of precious stones; it contains much oxide of lead, and also metallic oxides used for the

ANALYSES OF GLASS (from Dr. Knapp's "Chemical Technology").

* Relation between the oxygen of the acid and the total amount of oxygen in the bases.

colors. 7. Enamel, composed of silica, soda, and oxide of lead, but rendered opaque by oxide of tin or antimony, which form a stannate or antimoniate with the soda. To these may be added the soluble glass, which is a simple silicate of soda or of potash, or a mixture of the two silicates. The chemical formula of bottle glass No. 4 (see table on preceding page) is $\text{KO} + 8\text{CaO} + 2\text{Al}_2\text{O}_3 + \text{F}_2\text{O}_3 + 8\text{SiO}_2$; of window glass No. 1, $8\text{NaO} + 5\text{CaO} + 12\text{SiO}_2$; of plate glass No. 1, $2\text{NaO} + \text{CaO} + 6\text{SiO}_2$; of white glass No. 3, $\text{KO} + \text{CaO} + 8\text{SiO}_2$; of flint glass No. 2, $6\text{KO} + 9\text{PbO} + 20\text{SiO}_2$; or of strass (flint glass No. 3), $3\text{KO} + 9\text{PbO} + 16\text{SiO}_2$. The last variety, well known to chemists, is of variable composition, some qualities melting readily. To the later editions of Dr. Knapp's work are added the following more recent analyses by Peligot:

Varieties of glass.	Silica.	Potash.	Lime.	Alumina.	Soda.	Oxide of tin.	Oxide of lead.	Mel. copper.	Oxide of iron.

Bohemian mirror	67.7	21.0	9.9	1.4

The second of these is a remarkable glass, being a simple silicate of potash with 10 per cent. more silica than is contained in Fuchs's soluble glass (a notice of which is introduced near the close of this article). Particles of glass are dispersed through the semi-transparent, imperfectly melted mass. The compound is not attacked by boiling water, and does not attract moisture from the air. The ingredients of glass appear to be in the proportions of chemical equivalents—results, however, obtained by practice and not by mixtures made with this view. Various causes affect the stability of the combinations and the qualities of the compounds. The alkali in window glass powdered and moistened is detected by its action upon turmeric paper, and may be partially dissolved out by long continued digestion in boiling water. Atmospheric agents sometimes remove it in part from window panes, leaving a film of silica or silicate of lime. The glass of stable windows is liable to change its appearance, and assume prismatic colors, from the action of the ammoniacal vapors upon the silica. Changes in the degree of oxidation of its metallic ingredients, which are sometimes induced by atmospheric causes, are also attended by changes of colors. Long continued cooling has the effect of changing the structure, causing it to lose its transparency and become devitrified. Its ingredients form among themselves a new arrangement of their particles, and compounds are produced which assume a crystallized structure. By remelting, the vitreous character may be restored, though with a loss of a portion of potash which was volatilized in the devitrification. In making articles of glass, and especially bottles, it is necessary to guard against this tendency to crystallize, and shorten the process of annealing on account of it. Devitrified glass was first

described by Réaumur, and has hence been called Réaumur's porcelain. In consequence of the ease with which it may be made into any shape, and its tenacity and refractory nature, not unlike porcelain itself, it has been thought that it may be employed as a cheap substitute for this material, especially in many articles used in chemical laboratories.—The specific gravity of glass varies with its composition, from 2.4 to about 8.6. The determination of this may afford some hints as to the composition of crystal or flint glass, but is no index to that of the other varieties. Its density and also its refractive property are increased with the proportion of oxide of lead it contains. Brittleness is a quality that limits the alteration of the shape of glass within narrow bounds, after it has cooled; but when softened by heat while it is highly tenacious, no substance is more easily moulded into any form, and it can be blown by the breath into hollow vessels of which the substance is so thin that they may almost float in the air. It may also be rapidly drawn out into threads of several hundred feet in length; and these have been interwoven in fabrics of silk, producing a beautiful effect. In the soft plastic state it may be cut with knives and scissors like sheets of caoutchouc. It is then inelastic like wax; but when cooled, its fibres on being beaten fly back with a spring, and hollow balls of the material have, when dropped upon the smooth face of an anvil from the height of 10 or 12 feet, been found to rebound without fracture to $\frac{1}{2}$ or $\frac{3}{4}$ the same height. It has the valuable property of welding perfectly when red hot, and portions brought together are instantly united. When moderately heated it is readily broken in any direction by the sudden contraction caused by the application of a cold body to its surface. It is also divided when cold by breaking it along lines, cut to a slight depth by a diamond, or some other extremely hard-pointed body of the exact form suited for this purpose; and it may be bored with steel drills, provided these are kept slightly moistened with water, which forms a paste with the powder produced. Oil of turpentine, either alone or holding some camphor in solution, is also used for the same purpose. Copper tubes fed with emery also serve to bore holes in glass. Acids and alkalies act upon glass differently according to its composition, and reference should be made to this in storing different liquids in bottles. Silicate of alumina is readily attacked by acids, and bottles in which this is in excess are soon corroded even by the bitartrate of potash in wine, and by the reaction the liquor itself is contaminated. A glass that loses its polish by heat is sure to be attacked by acids. Oxide of lead when used in large proportion is liable to be in part reduced to a metallic state by different chemical reagents, and give a black color to the glass. All glasses are attacked by hydrofluoric acid.—The crude materials employed in the manufacture of glass are selected with more or less care according to the quality of the

articles to be produced. Silica is obtained in the form of quartz sand from sea beaches and from the disintegration of quartzose rocks in the interior. It was in England once procured from flints calcined and ground to powder, whence the name flint glass. Sand is now used instead, and a highly prized article is imported into England from Australia. In the United States the purest is from Lanesborough, Mass. It is disintegrated quartz rock, a member of the metamorphic group. As quarried, it retains the marks of stratification, and thin films of white talc coat its seams. It is easily broken down by the pick, and lumps of it are crushed in the hand. The sand is washed in a stream of water to separate the talcose impurities, and is then ready for the market. The grains are remarkable for their purity; in the mass they appear white, but under the microscope each grain is limpid like a clear quartz crystal. This sand is suitable for the best flint and plate glass. Other qualities are procured in various parts of the country. Lime may be used either in the state of quicklime or in limestone of the purest qualities. Common wood ashes have been used to furnish potash, and ashes of sea plants to furnish soda; but these have been replaced by the crude alkalis obtained from them and other sources, and for some purposes the refined pearlash is employed. The carbonate of soda is also extensively prepared from common salt; and at Newcastle, England, black bottles are made from rock salt and sand from the bed of the river, with carbonate of lime of the soap works and the tank waste of the alkali makers. Sulphate of soda, the waste product of many chemical works, is successfully used, except for plate glass. Of the oxides of lead, the minium, or red lead (Pb_2O_3), is preferred to the litharge (PbO), on account of its finer state of division and the beneficial effects of the excess of oxygen, which carries off with it any carbonaceous impurities or particles of soot that may be present in the melted mass. Saltpetre and bin-oxide of manganese and arsenic also are often introduced into the mixtures with the view of promoting the same object. Alumina and oxide of iron are commonly not intentionally used; they come from the impurities of the other materials. Waste glass, called cullet, forms a considerable proportion of the raw materials in some works; it promotes the fusion and the chemical union of the silica and bases mixed with it, but must be well sorted, so that no qualities be introduced inferior to that intended to be made. Feldspar, which contains the essential elements of glass, is recommended to be used as one of the raw materials. Basalt also might no doubt be made to serve a useful purpose, as the lavas of the extinct volcanoes of central France were successfully employed in the last century in the manufacture of glass bottles. The following receipts give the proportions of the ingredients used for various kinds of glass at different works; 100 lbs. of sand being employed in all cases where it is not specified:

ORDINARY FRENCH BOTTLE GLASS—Varec, 30-40 lbs.; lixiviated ashes, 160-170; fresh ashes, 30-40; clay containing iron, 80-100; broken glass, 100.

ENGLISH BOTTLE GLASS—Lixiviated ashes, 100 lbs.; kelp, 40-90; wood ashes, 30-40; clay, 50-100; cullet, 100.

CHAMPAGNE BOTTLES—Feldspar, 200 lbs.; lime, 20; common salt, 15; iron slag, 125.

ORDINARY GREEN BOTTLE GLASS—Lime, 72 lbs.; lixiviated wood ashes, 230-275.

DARK GREEN BOTTLES—Dry Glauber's salt, 20 lbs.; soap boiler's flux, 18; Scheffel (Pruss.) lixiviated ash, 1; glass from the hearth, 30; green cullet, broken glass, 179; le-salt, 45.

APOTHECARIES' VIALS—Potash, impure, 30-35 lbs.; lime 17; ashes, 110-120; bin-oxide of manganese (cullet), 0.25-0.54.

BOHEMIAN CRYSTAL FOR GRINDING—Purified potash, 6-8 lbs.; chalk, 8; broken glass, 40; manganese, 0-73.

SEMI-WHITE—Crude soda, containing lime, 100 lbs.; cullet, 100; manganese, 0.5-1; or, potassa, 30; lime and decolorizing matters, 13.

CLEAR WHITE—Calcined potash, 65 lbs.; fullers' lime, 4; white cullet, 100; manganese, 0.5.

WHITE (for chemical purposes)—Potash, 41.4 lbs.; lime, 17.3.

WINDOW GLASS, FRENCH—Sand, 100 lbs.; chalk, 35-40; dry carbonate of soda, 28-35; broken glass, 60-150; manganese, 0.25; arsenic, 0.20; of the last two, sometimes much more.

WINDOW GLASS, FRENCH.

Materials.	No. 1, lbs.	No. 2, lbs.
Sand	100	100.0
Dry sulphate of soda	44	53.0 to 73.0
Charcoal in powder	4	4.5 to 5.5
Slaked lime	6	13.0 to 15.0
Broken glass	20 to 100	25.0 to 101.0

WINDOW GLASS, ENGLISH.

Materials.	No. 1, lbs.	No. 2, lbs.	No. 3, cwt.
Sand	560	448	16.00
Chalk	154	146	5.00
Carbonate of soda	119	168	5.00
Sulphate of soda	68	17	1.25
Arsenic	2	2
Cullet	448	448	16.00

PLATE GLASS, ST. GOBAIN.

Materials.	No. 1, lbs.	No. 2, lbs.
Pure sand from Senlis	100	100
Pure salts of soda	35	60
Lime crumbled	5 carb.	18
Broken glass	100	100
Decoloring matters	110, 0.5 small.

PLATE GLASS, ENGLISH—Lynn sand, washed and dried, 730 lbs.; alkaline salt, containing 40 per cent. of soda, 420; lime, slaked and sifted, 80; nitre, 25; broken plate glass, 425; product, 1,200 lbs. of glass.

FLINT GLASS, ENGLISH (A. Pellatt)—Carbonate of potash 175 lbs.; red lead or litharge, 224; sand, washed and burned, 386; saltpetre, 14-28; oxide of manganese, 0.25-0.75; broken glass, *ad libitum*.

FLINT GLASS, FRENCH.

Materials.	Summer use, draft poor.		Coal for fuel.	Wood for fuel.
Pure sand	500	800.00	100	100
Minium	215	180.00	70	45
Purified potash	110	120.00	30	35
Nitrate of potash	10
Borax	12
Cullet	800.00
Arsenious acid	0.45
Oxide of manganese	0.60

OPTICAL GLASS, BONTAPPE.

For flint glass.		For crown glass.	
Sand	48.5	Sand	60
Red lead	48.5	Carbonate of soda	35
Carbonate of potash	10.0	Carbonate of lime	14
Nitrate of potash	8.0	Arsenic	1

OPTICAL GLASS (Faraday's heavy)—Protioxide of lead, 164 lbs.; silicate of lead, 24; dry boracic acid, 25.

STRASS, THE BASIS OF ARTIFICIAL GEMS.

Materials.	No. 1.	No. 2.	No. 3.
Ground quartz crystal, or pure sand	100.0	100.0	100.00
Pure minium.....	156.0	154.00
White lead.....	171.0
Pure caustic potash.....	54.0	82.0	54.00
Boric acid.....	7.0	9.0	6.00
Arsenious acid.....	0.8	0.8	0.16

The proportions given in the above receipts are variously modified by different manufacturers. Compounds will not produce the same results in all furnaces, nor in the same furnace under different conditions of draft, fuel, weather, &c. As in the smelting of ores, a skilful manufacturer will know how to vary the charges to suit circumstances.—The fuels used for melting glass may be bituminous coal or its coke, thoroughly seasoned wood, and perfectly dry peat. Pine wood is preferred to the harder kinds; and all are improved by kiln drying, carried to the point of browning the wood. Rosin is used in some American works to the exclusion of other fuel; it is pulverized and added in small quantities at a time, leaves no residuum in burning, and does not produce any impurities that can mix with or injure the glass. The raw materials, thoroughly ground, mixed together, and sifted, are well incorporated with from $\frac{1}{4}$ to $\frac{1}{2}$ of their weight of broken glass before being introduced into the melting pots. These are already heated to a white heat in the furnace, and receive only $\frac{1}{4}$ of a charge at a time, more being added as the first portion melts down. The pot being at last filled with the melted "metal," the fires are vigorously pushed, and the progress of the operation is judged of by the workmen dipping iron rods from time to time into the mixture and examining the appearance of the drops withdrawn. A nearly homogeneous product, which becomes transparent on cooling, indicates that the most refractory ingredients have been all dissolved. Their mixture has been facilitated by the continual disengagement of carbonic acid gas, which in its escape caused the whole to be thrown into ebullition. Some of the gas remains in the mass, rendering it spongy and full of vesicles. Unless in the manufacture of the finer qualities of glass, for which the purest materials are employed, there is also a scum, called glass gall or sandiver, floating upon the surface, consisting of the insoluble matters, and the sulphates of soda and lime not taken up by the mixture. This is removed by lading, and the "metal" is next fined, which is done by increasing the heat to the highest degree, and keeping the contents of the pots in a state of perfect fluidity from 40 to 48 hours; in this time the bubbles disappear and the insoluble matters settle to the bottom. The furnace is then allowed to cool until the metal has become viscid, so that it may be taken out and worked; and it is afterward kept at sufficiently high temperature to maintain the glass in this condition, that it may be used as required. The arrangements of the great circular glass furnaces, with their central

fire surrounded with 8 to 12 pots, each reached by its own arch under the general dome, admit of enough material being melted at once to employ all hands the first 4 working days of the week, the men working day and night in 6 hour shifts. The materials of the furnaces and pots, calculated to withstand the excessive heat and the action of the various melted ingredients, must of course be carefully selected from the most refractory substances, and the work must be most skilfully executed. The construction of the great melting pots is an object of special solicitude, and the placing of a new one in the furnace while this is in operation is a task of no little apparent difficulty and danger.—Such is a mere outline of the means employed to bring the materials of glass into their desired combination. The production of each kind of glass is a separate branch of manufacture, involving many curious details and processes, too numerous even to be named in this account, and all dependent upon illustrations for an intelligible description. The tools employed are few and simple, and differ but little from those described in the work of Blancourt, "On the Art of Glass," published in London in 1699. The first in importance is the pipe or blowing tube, made of wrought iron, 4 or 5 feet long, with a bore from $\frac{1}{4}$ to 1 inch in diameter, a little larger at the mouth end than at the other. It is a long hand, with which, the end being heated red hot, the workman reaches into the pot of melted matter and gathers up the quantity he requires, and which afterward holds the article in the manipulations to which he subjects it; and it is at the same time the air tube through which the breath is forced to expand the vessel, or through which water is sometimes blown to produce the same effect by the steam it generates. A solid rod of iron, called a ponty or pontil, serves to receive the article upon its end when freed from the pipe, adhesion being secured by the softness of the glass or by a little red-hot lump already attached to the pontil. Spring tongs, like sugar tongs, are used to take up bits of melted glass; and a heavier pair, called pucellas, furnished with broad but blunt blades, serve to give shape to the articles as the instrument in the right hand of the workman is pressed upon their surface, while, seated upon his bench, he causes with his left hand the rod holding the article to roll up and down the two long iron arms of his seat, upon which it is laid horizontally before him. The operation is like the shaping of clay vessels upon the potter's wheel, the pipe or the pontil serving in the place of the wheel or of a lathe. It is more complicated, as the vessel is also shaped from the interior as well, and is occasionally applied to the opening of the furnace to soften it entirely or only in some part to which greater distention is given by blowing. Another important instrument is a pair of shears, with which a skilful workman will cut off with one clip the top of a wine glass, as he twirls it round with the rod to which it is attached held in the left

hand. The edge softened in the fire is then smoothed and polished. Beside these a wooden utensil called a battledoor is employed, with which the glass is flattened by beating when necessary; compasses and calipers and a measure stick are at hand for measuring; and a slender rod of iron forked at one end is used to take up the articles, and carry them when shaped to the annealing oven, in which they are left for some time to be tempered. (See ANNEALING.) The marver (Fr. *marbre*, marble) is a smooth polished cast iron slab, upon the surface of which the workman rolls the glass at the end of his tube in order to give it a perfectly circular form. Those used in the manufacture of common black bottles are furnished on one edge with several concavities, in which the mass of metal taken from the melting pot is first roughly shaped as it is rolled over and over and made to swell by gentle blowing. The fine ornamental bottles of flint glass are shaped more completely by blowing them in moulds of brass or iron, which are made in two parts hinged together, so that they may be opened and shut with the foot. Bottles for champagne and aerated waters are made of extraordinary strength, and are sometimes tested by the pressure of water before using. They ought all to be able to support a pressure of from 25 to 35 atmospheres; some have been known to withstand a pressure of more than 40 atmospheres, or more than 600 lbs. on the square inch.—The method of drawing out tubes affords an interesting and not very familiar example of the curious and ingenious manipulations in the making of this substance. The workman, called the gatherer, introduces the red-hot end or nose of the blowing tube into the pot, and gathering up a portion of the metal, takes it out, suffers it to cool a little, and blows into it, to make it swell. Another dip accumulates more, and so on till enough is gathered. This being then blown into a globular form with very thick walls, the pontil, by means of a lump of melted glass at one end, is secured by another workman exactly opposite the tube, the two lying in one line, which passes through the centre of the globe. The two men then separate from each other as quickly as possible. The globe immediately contracts across its centre, which, being drawn out to the size of the tube desired, cools, so that the hotter and softer portions next yield in their dimensions, and so on until a tube of 100 feet or more in length hangs between the two men, sagging in the middle like a heavy rope. It is kept constantly rotating in the hands, and is straightened as it cools and sets by placing it on the ground. It is cut into suitable lengths while hot by taking hold of it with cold tongs. The diameter of the bore retains its proportion to the thickness of the glass; hence thin tubes must be drawn from globes blown to large size, or from small ones containing very little metal.—Tubes thus drawn out from colored glass are converted into beads

by processes which further illustrate the various and curious manipulations of this art. This branch of the manufacture is extensively practised at Murano. The tubes are drawn out 150 feet in length, and to the diameter of a goose quill; those for the smallest beads by the workmen receding from each other at a pretty rapid trot. The tubes are cut into lengths of about 27 inches and assorted for size and color. Women or boys then take several together in the left hand, and run them on the face of an anvil up to a certain measure, and with a blunt steel edge break off the ends all of the same length, which is commonly about twice the diameter of the tubes; the bits fall into a box. These are next worked about in a moistened mixture of wood ashes and sand, with which the cylindrical pieces become filled; and they are then introduced with more sand into a hollow cylindrical vessel, which is placed in a furnace and made to revolve. The glass softens, but the paste within the bits prevents their sides from being compressed; they become spherical, and their edges are smoothed and polished by the friction. When taken from the fire and cleaned from the sand, they are ready to be put up for the market.—Glass for window panes, commonly known as English crown glass, is one of the hardest varieties, and of unsuitable quality for shaping into vessels or manufacturing by cutting or grinding. In making it, the glass is first blown into a globe, and this is flattened out into a circular disk, which is afterward cut up into panes. The workman learns by experience to gather upon the tube the exact quantity of glass required, which varies not over an ounce, more or less, from 9 pounds. The pipe being cooled to admit of handling, the lump is rolled upon the marver to give it a conical form, and a boy blowing at the same time through the tube causes the glass to swell. It is now heated by holding it in the furnace, and is then again rolled and enlarged by blowing. The most of the glass is worked down to the end of the conical or pear-shaped lump, the upper part being hollow. The solid end is called the bullion. This being softened in the furnace, the tube is laid across a rest and twirled around, while the glass is blown into a globe. The heavy soft end is moreover supported by a boy, standing opposite to the man who blows, and holding it up by the end of an iron rod placed in line with the blowing tube. The globe at the end of the tube is now pointed toward the flame of the furnace, and being constantly twirled, the extreme end toward the fire flattens out, the bullion point still forming a prominence of thicker metal in the centre. To this centre a pontil with a lump of molten glass at its end is next attached, and the blowing pipe is separated by applying a piece of cold iron around the nose. As it breaks away it takes a portion of glass with it, leaving a circular opening. Taken up by the pontil, the glass is held with the nose (or portion to which the blowing pipe had been attached) presented to the so called nose hole

of the furnace. Here it is softened almost to melting, while it is all the time twirled around; it is then presented to the flame issuing from the great circular opening of the so called flashing furnace, the man holding it being protected from the fire by a covering over his head and face. Rapidly revolving in this flame, the opening in the end grows larger; the heated air within prevents the two opposite faces of the flattened spheroid from coming together, and the centrifugal force is constantly enlarging its diameter. The opening rapidly increases, the portion next the fire seems to roll inside out; a glimpse is caught of a large circle with a double rim; and in an instant it has burst open into a flat circular disk with a noise like that produced by suddenly opening a wet umbrella. The disk removed from the fire is kept rapidly revolving until it is cool enough to retain its form. The pontil is then cracked off, and the disk or table is removed upon a fork to the annealing oven and set up on edge with the rest, arranged in rows and supported by iron rods so as not to press against each other, and the thicker part in the centre, called the bullion point or bull's eye, also keeping the tables apart and open for the circulation of air. The annealing is completed in from 24 to 48 hours. Tables are thus commonly made of 52 inches diameter; but some have been produced of 70 inches, and some were exhibited by the Messrs. Chance in the great exhibition of 1851 of 66 inches diameter. A single pot containing half a ton commonly produces 100 tables; and in the crown glass houses it is customary to empty 8 such pots in 3 days every week. From the annealing kiln the tables are taken to the warehouse and sorted according to their different qualities and defects. Each one is then laid in turn upon a "nest" or cushion, and is divided by the diamond into two pieces, the larger one containing the bull's eye. These are next cut up into rectangular panes. The shape and the bull's eye involve considerable waste in cutting; but the remarkable brilliancy of the glass compensates for this loss. The best used for windows, excepting plate glass, is the English crown glass, made as above described; until the year 1838 it was the only kind successfully made for this purpose in England. Another process was in use on the continent, by which a coarser article, known as spread window glass, cylinder glass, &c., was made; and this method being introduced by the Messrs. Chance and co. of West Bromwich, near Birmingham, in 1832, was in a few years perfected, to the great improvement of the manufacture. The process, however, can hardly be called new, for in the *Dictionarium Artis Schedula*, a work probably of the 18th century, it is described; and it was practised in England and given up for the rotary method at a very early period, as this on the continent was abandoned long ago for the other. The same material is used in both cases; but by converting the glass spheroid into the form of a cylinder, cutting off or bursting open the ends of this,

and with a pair of shears or other method alitting the cylinder its whole length, a broad sheet of glass can then be spread out, making a much larger pane than can be procured by the rotary process. Of crown glass it is difficult to obtain panes of 84×22 inches; but the common size of sheet glass, as the cylinder glass is called, is 47×82 inches, and it is sometimes made 50×36. Cylinders indeed have been blown 77 inches long, requiring a lump of glass of 38 lbs. weight. To obtain the cylindrical form the following method is practised, and usually by a number of workmen together, each at his own furnace hole, of which 10 are sometimes ranged side by side with a raised platform extending in front of each furnace 10 feet above the bottom. Standing upon this, each man gathers a proper quantity of metal, and getting it first into a spheroidal state by blowing and applying the lump to a wooden mould, he holds it after reheating vertically over his head, that the sphere may flatten down, still blowing into the tube. The tube is then brought down, and swung in the pit below the platform, so that the glass may elongate into the form of a cylinder, the blowing being continued; and if the extension takes place too rapidly, it is again held up inverted. Thus the operation is dexterously managed until the cylinder obtains its full dimensions of about 47 inches long, and 10 to 11 inches diameter. The closed end being softened by holding it to the fire, and the pipe being closed by the thumb at the same time, the air within is expanded by the heat and bursts that end open. The edges are next brought out to the full diameter and trimmed. The tube end is cut off when the glass is cool by the application of a red-hot curved iron around its surface, and letting fall a drop of water upon the heated line; and the cylinder is split either in a similar way or better by the diamond, which is applied along a rule laid inside the cylinder. The cylinders are now taken to the flattening furnace, and introduced one by one upon a spreading plate or flattening stone, the slit uppermost. Here as they soften they open out in a sheet, the workman introducing an iron rod, and with it aiding the movement; with another rod, having a block of wood at its extremity for polishing the sheet, he next works down the protuberances and irregularities of the surface. The sheet is then passed into the adjoining oven for annealing. In every one of the processes to which it has been subjected, it was exposed to some imperfection, and some of the sheets bear the peculiar defects of them all, and are worthless; others answer for inferior uses, and but few are perfect; none have the brilliancy of crown glass, and the effect of the unequal lengths of the inner and outer surfaces of the cylinder is to produce a kind of undulating appearance called cockles, which distorts objects seen through the glass. The uneven surface of the sheets rendered attempts to polish the glass unsuccessful, until the ingenious method devised by Mr. James Chance was applied to

this purpose. Each sheet was laid and pressed upon a sheet of soft leather, which, acting as a "sucker," adhered to the glass by atmospheric pressure. Two plates thus treated were laid face to face, and by ingenious machinery rapidly rubbed with the intervention of polishing sand and water. After the removal of the leather the sheets by their elasticity regained their former somewhat curved surface, but in the mean time the faces were thoroughly polished and made as beautiful as plate glass. Excepting for mirrors, the cheap glass thus made is equal to the most expensive kinds. The Venetian method of polishing the great mirrors by imbedding them in plaster of Paris admitted of their being ground to a perfect level and acquiring a brilliancy equal to that of the cast plate. The practice was extended into Bohemia and Bavaria, and is now carried on in Germany, and was applied to plate window glass of moderate sizes. The introduction of soda ash about the year 1885, for the sake of economy in fuel by the greater fusibility it caused in the glass, gave it the bad quality of "rusting," or becoming dull by exposure to the air, rendering it unfit for windows. One German factory alone retains the old practice, and supplies the fine plate glass for the house of Messrs. Roosevelt and son of New York. Sheet glass manufactured by Messrs. Chance and co. was used for the building of the great exhibition of 1851. The cylinders when flattened cut 49×30 inches, and were subdivided into 8 panes of 49×10. The number of these required was about 300,000, of more than 400 tons weight. The setting of them was accomplished as rapidly as their manufacture. In one week 18,392 panes were set by 80 glaziers, and one man set 108 panes in a single day.—Plate glass, largely used for mirrors, and of late for windows also, is now made, as already mentioned, by casting. The mixtures employed do not vary much from those for making sheet glass, except by the introduction of a considerable proportion of soda, which has the effect of making the compound more fluid, but it is apt to impart to it also a greenish or bluish tinge. The greatest care is required in the selection and preparation of the materials to insure a pure and transparent glass free from all defects which tend to refract or reflect the light irregularly and distort the image. As the glass is melted in the pots it is ladled into cisterns or *cuvettes*, placed in the fire by the side of the pots, or, as in Berkshire, Mass., the pot is raised and emptied directly upon the casting table. In France 16 hours are allowed for the melting, and the same time for the metal to remain in the *cuvettes*; but the latter term is sometimes extended to 24 or even 48 hours, the object being for the aeriform bubbles to escape, and the excess of soda to be volatilized. Toward the last the temperature is allowed to fall, and the glass then acquires the slight degree of viscosity suitable for casting. The annealing furnace is at the same time heated, and the metallic plate or table upon which

the glass is to be cast is covered with hot coals for the same purpose. This important part of the apparatus used formerly to be made of bronze; and the great slab of St. Gobain of this alloy weighed 50,000 lbs., and cost 100,000 francs. The British plate company found cast iron less liable to crack, and this metal is now used for the purpose. At the Thames plate glass works the tables are 20 feet long, 11 broad, and 7 inches thick. The extent of the foundry room at Ravenhead is said to be 339 by 155 feet, the furnaces occupying the centre, and the annealing ovens ranged along the sides in front of the furnaces. Each oven is 16 feet wide and 40 feet deep; and its floor is level with the surface of the casting table. The cistern of melted glass taken from the furnace is swung by a crane and carried to the casting tables, the surface of which is carefully cleaned. The melted glass is skimmed with a copper blade, and the cistern being then hoisted to a proper elevation it is cantoned over, and the glass is poured out over the table; ledges of metal around the sides prevent its flowing over, and by their height regulate the thickness of the glass. A copper cylinder 8 feet in diameter extends across the table, resting on the ledges; and being rolled forward, it sweeps before it the excess of glass, and spreads it in a sheet of uniform thickness. The operation is a beautiful one from the brilliancy of the great surface of melted glass and the play of colors exhibited upon it after the passage of the roller. The plate being trimmed of the superfluous glass around its edges, and the back end being turned up like a flange, an iron rake-like instrument is applied to it, by which the plate is thrust forward upon the sanded brick floor into the annealing oven, the temperature of which is that of dull redness. By the force thus exerted the upper surface is somewhat wrinkled, but the marks of this disappear in the subsequent polishing. Another plate is now immediately cast upon the hot table, and the annealing oven when filled is closed up and left for 5 days or longer to cool; in France less time is given to this process. When removed from the oven the plates are carefully examined to see how they will out to best advantage and avoid the parts which exhibit defects. They are cut in squares with a diamond, and the roughness of the edges is removed with a pair of pincers. Different methods of grinding and polishing the plates are in use, the most approved of which is a late American invention introduced into England in 1856, and adopted in the British plate glass works. A circular plate of cast iron, sometimes 10 feet in diameter and 2 inches thick, is secured upon the upper end of a vertical shaft, so as to revolve with it. Above the table frames are arranged to hold the plates of glass, which are laid in a bed of plaster of Paris, with the face to be polished resting upon the table. These frames also revolve on their centres by the friction of the table upon the glass, of course slowly, but so as to present each side of the plates they

hold to an equal amount of rubbing as they are moved nearer to the centre of the table or further from it. Sand is used to grind down the glass, and this is fed from a box above as required. The grinding by this process is found to be even and equal, and the machinery to work smoothly and steadily from the facility with which the plates accommodate themselves to the power applied. In other operations one plate has been ground upon the face of another, being turned over and ground on their opposite sides when the first are completed. After grinding they are smoothed with emery powder of finer and finer qualities, and are thus prepared for polishing. This is accomplished in the American machine by having the cast iron table covered with rings coated with felt, which are screwed to its surface. The polishing material applied to the felt is oxide of iron or rouge. Polishing sometimes brings out defects which were before concealed; the plates are consequently again assorted, and, if need be, reduced to smaller sizes. (For the methods of silvering them, see MIRROR.) Bending the large plates or the smaller sheets of glass for the purpose of fitting them for bow windows, &c., is an especial branch of the manufacture, more extensively practised at the works of Messrs. Cooper and Belcher at Newark, N. J., than elsewhere. A core of refractory material and suitable shape is introduced upon the floor of the furnace; and upon this is laid the sheet to be bent, which as it softens by gravity conforms itself to the shape of the bed upon which it is laid. —Of the various kinds of glass in common use, none require more care to insure the purity of the materials employed than the crystal or flint glass, of which are made many choice articles for domestic purposes, some of which are subjected to the processes of cutting or grinding and polishing. It possesses the properties of great transparency and high refractive power, which fit it for lenses for optical instruments. Flints calcined and ground were formerly used to furnish the silica, but pure sand is now generally used instead. Oxide of lead enters largely into its composition, and to this are due its brilliancy, density, and comparative softness. The oxide should be prepared especially for the purpose to insure its purity. Oxide of zinc has been found to produce similar effects. As the glass is essentially and peculiarly of metallic composition, it might better be distinguished by this name than by those now applied to it. In the melting it is found necessary to use pots closed at the top with the opening made in a short neck on one side; this is to protect the melted matter from the smoke, which would discolor it, but the economy of direct exposure to the flame is thus lost. The English pots hold each about 18 cwt. The fusion must be rapid and at intense heat, and this must be reduced as soon as the metal is thoroughly melted and refined by the escape of the bubbles of gas, or the product acts upon the alumina and iron of the pot, and is thus so contaminated as

to be worthless. The method of shaping the articles by blowing them in a mould is applied to many of the vessels made of flint glass; and that the polish may not be affected it is necessary to keep the moulds nearly at a red heat as they are used. This glass is also shaped by the American process of pressing the soft metal in a die of the required form, into which it is introduced. For large articles considerable pressure is applied. The die is kept at a heat approaching redness, and at each operation must be furnished at once with the exact quantity of melted glass necessary to fill it, a feat which requires skill and practice. The process called cutting glass is in reality grinding and afterward polishing it. It is easily effected upon the soft flint glass by applying the surfaces to be cut to the face of revolving disks of iron or copper fed with emery, or, for coarse grinding, with sand and water. Stones are also used instead of the metallic disks. The marks of the rough grinding are removed by a smooth grindstone, and the polishing is then completed by wooden disks, to which pumice or rotten stone, and finally the preparation of tin and lead called putty powder, are applied. The fine polishing of chandelier drops is effected by a lead wheel supplied with fine rotten stone and water. Glass globes and lamp shades acquire their interior ground surface by the wearing action of sand placed within them, the globes being themselves introduced into the interior of a drum which is caused to rotate rapidly. Letters and designs are engraved on glass by means of small disks of copper set in rapid revolution, and fed with fine emery mixed with oil (see GEM ENGRAVING); or they may be etched. —No glass is of such importance in the arts as that of which the lenses of optical instruments are made. Both flint and crown glass are applied to this use, each of which has its defects; the former, from the great difference in the densities of its ingredients, is with much difficulty obtained of homogeneous structure, an essential requisite in all glass used for optical purposes; and the latter is difficult to procure of uniform composition and texture, from the high temperature required for its fusion and the consequent tendency to devitrify in cooling; or if this is obviated by increased proportion of alkali in the composition, the excess of this causes attraction of moisture from the air and a damp surface to the lens. So difficult was it to obtain even a moderate quantity of homogeneous glass, that until the production of the lenses of Guinand, a Swiss clockmaker, in the early part of the present century, the size of the largest objectives was limited to about $8\frac{1}{4}$ inches. By methods of his own he made with his own hands the furnaces, crucibles, and mixtures he employed, and produced the glass, which he shaped and polished, giving without knowledge of mathematics the requisite proportion to the curves of its surface, and completed lenses of flint glass of great perfection of structure, 9 inches in diameter. The secret of his success in making the glass is believed to

have consisted in keeping the mixture agitated by stirring when at its greatest liquidity, and then suffering it to cool and anneal in the pot. From the most perfect portions of the comparatively homogeneous mass thus obtained, the lenses were cut out by a process similar to that of sawing blocks of stone. By one of the sons of Guinand the secret was imparted to M. Bontemps; and in 1828 lenses were made in France of 12 to 14 inches diameter. In 1848 Bontemps removed to England, to join with the Messrs. Chance and co.; and the result of their operations has been the production of disks of flint glass 29 inches in diameter, weighing 2 cwt., and of crown glass 20 inches. These are of pure color, and of such homogeneous structure that the light is transmitted without polarization. Prof. Faraday, one of a committee appointed by the astronomical society of London to experiment upon the means of producing optical lenses, while Guinand's secret method of making these 6 inches in diameter was exciting the admiration of the scientific world, discovered the heavy glass called by his name, the composition of which has already been given, and which has proved of importance in investigations connected with the polarization of light; but its liability to change unfits it for general optical uses. Lenses both of flint and of crown glass are used in the object glass of achromatic telescopes, serving by their combination to counteract the unequal tendency of each to disperse the rays of light. The new optical glass of M. Maës of France has been found an excellent substitute for the crown glass lens; its basis is oxide of zinc, to which borax or boric acid is added. The subject will be further treated in the article *LENSES*.—The colored glasses are produced either upon the colorless composition called *strass* for imitations of precious stones (see *GEMS, ARTIFICIAL*), or by introducing the various oxides used for coloring into the materials of flint or other kinds of glass. Pigments are also applied to the surface of glass, and sometimes by their greater fusibility are burnt or melted in. Flint glass designed for vessels ornamented with colors may be employed of the composition already given as that of Mr. A. Pellatt, and to 6 cwt. of it the following ingredients are added for producing the respective colors: soft white enamel, 24 lbs. arsenic, 6 lbs. antimony; hard white enamel, 200 lbs. putty, prepared from tin and lead; blue transparent glass, 2 lbs. oxide of cobalt; azure blue, about 6 lbs. oxide of copper; ruby red, 4 oz. oxide of gold; amethyst or purple, 20 lbs. oxide of manganese; common orange, 12 lbs. iron ore and 4 lbs. manganese; emerald green, 12 lbs. copper scales and 12 lbs. iron ore; gold topaz color, 8 lbs. oxide of uranium. The colors produced by the metallic oxides are found to vary with the degree of heat employed. All the colors of the spectrum may be obtained with oxide of iron; and these various results do not seem to depend upon the different degrees of oxidation, but are thought to result from variations in mole-

cular arrangement, induced perhaps by the action of light. Some of the methods of coloring the surface of glass are too ingenious and curious not to be noticed. The quantity of coloring matter required is often exceedingly small, and may advantageously be incorporated merely with the outer portion of the glass. This is effected in the blowing by dipping the lump of clear glass, when shaped upon the marver, into the pot of melted colored glass, and then blowing it to the shape required, and flashing out if desired to convert it into panes. The color may be afterward reduced in intensity by grinding, and colorless facets be produced by cutting through the outer portion to the clear glass beneath. "Casing" is a somewhat similar process. The article of flint glass when partially blown is inserted into a thin shell of colored glass, prepared at the same time for its reception, and the blowing is continued till the inner one fills the shell, with which it is afterward well incorporated by softening in the furnace and further blowing. Several partial casings of different colors may be thus applied. Painting is the external application of colors mixed with a flux of much easier fusion than the glass, and with some vehicle, as boiled oil or spirits of turpentine. The mixture is laid on with a brush as in ordinary painting, or by blocks as in printing cloths; and the glass being then exposed to heat, the flux melts and sinks into the body. None of the clear bright colors are perceived until the work is completed, and the artist consequently labors under great disadvantage in applying the materials that are to produce them. He is guided either by lines drawn on the back side, which show through, or by a cartoon or drawing on paper placed there. The flux, if the coloring oxides are such as not to be affected by oxides of lead and bismuth, is composed of 100 parts of pulverized quartz, 135 of oxide of lead, and 50 of oxide of bismuth; or, if otherwise, with the same quantity of quartz are mixed 75 parts of glass of borax, 12½ of saltpetre, and 12½ of pure carbonate of lime. In the early use of glass for windows, especially those of churches, brilliant colors were highly esteemed, and great success was attained in the methods of coloring. The art fell into disuse, and the processes were lost, though the receipts for them were still to be found in the ancient treatises. This was particularly the case with the bright red color, which was imparted by the ancients with the protoxide of copper. In later times it was found impracticable to succeed with this on account of the tendency of the copper to pass to a peroxide and produce a green tinge; of late the practice is again introduced with success by the Tyne company in England, at Choisy in France, and other places. The discovery of the preparation of gold and tin, called purple of Cassius, also afforded another means of producing a brilliant red, as noticed in *GEMS, ARTIFICIAL*. Notwithstanding the introduction of processes not formerly known, and a more

exact understanding of the effects of the various oxides, which probably cause the art to be now better understood than ever before, the colors are considered less brilliant than those of ancient times. From this description it appears that what is called glass painting, which is more properly a process of staining, differs from all other styles of the pictorial art, except the painting of porcelain. The colors are different, being wholly of mineral composition, and are not merely laid on the outside, but are fixed by being fused into the material, undergoing in the operation chemical changes that develop the brilliancy and transparency of which the compounds are susceptible. Thus the colors are removed from the influence of external causes of change, and are permanently retained upon the most fragile of materials.—Soon after the introduction of glass into windows its appropriateness as a medium when colored for ornamentation of churches and other public edifices was perceived, and its first use for this purpose is believed to have been at the time when the ancient basilicas were converted into Christian temples, which, it is said, were adorned with stained glass. The magnificent churches erected on the continent of Europe in the 9th century were also generally thus ornamented. The glass was in small pieces brilliantly colored throughout, and set in leaden lines which were the outlines of the designs. Pictorial illustrations are not known to have been introduced before the 11th century. At that period there was a glass picture in a church window of the monastery of Dijon, which represented the mystery of the holy eucharist. In the year 949 mention was made, according to Mrs. Merrifield, of "a portrait of King Constantine (VII.) admirably executed on stained glass." In the ancient glass pictures the figures were formed of pieces of stained glass, and the shadows were laid on with dark colors and fixed in the fire. Intense colors were exclusively employed, the ruby and blue always predominant. The ground was mosaic in circles, squares, and lozenges, of massive forms, and filled with foliated ornaments in the Roman style. Over this were medallions representing historical and biographical subjects from the lives of the saints. When figures came to be introduced they were generally grotesque and distorted; but the costumes were remarkably correct. The designs always harmonized with the style of architecture, stately and magnificent in the Norman structures, and light and elegant in those of the early English models in the 13th century. In these the brilliant positive colors were made more subsidiary, appearing in borders, geometric bands, and central points, while the ground was of a neutral gray, produced by lines crossing each other at right angles. The designs were also more correctly drawn, and shaded with greater delicacy. For the violet tint always before used for the faces of the figures was substituted a gray or brown upon colorless glass. The pieces of glass were of larger size, and a single figure often was made to occupy a

whole window, standing beneath an elaborate blue or red canopy. In the background among the architectural fragmentary designs still appeared the old Roman foliated ornaments, but intermixed with original studies from nature, a style of the art which was afterward carried to great perfection. Not only leaves, plants, and trees, but even landscapes and buildings in perspective, appeared in the latter half of the 15th century; the smaller objects being introduced among the elaborate geometrical figures, which were arranged somewhat like frames around the principal figures. The Scripture pieces were often explained by legends painted upon the phylacteries, and in the background were represented rich blue or red hangings of damask. Among the glass pictures of the 16th century are found the finest specimens of the art. The most eminent painters practised it, as Albert Dürer, Claude, Palissy, and others, and their works are still admired in the churches of that period, as the Cologne cathedral, York minster, and many others. But in the next century the art had entirely declined, and has since found few votaries, for the reason, as Labarte suggests in his "Illustrated Handbook," that its intention was perverted in the transformation of an art of purely monumental decoration into an art of expression. For this oil painting possessed greater resources, and glass painting necessarily fell into neglect. In some modern attempts it is remarked that the primary object of the glass in transmitting light appears to be overlooked and sacrificed in the opaque shadows introduced. In 1890 a gorgeous glass picture representing the tourney between Henry VIII. and Francis I., at Ardres, June 25, 1520, was exhibited in Oxford street, London. It was a window 18 feet by 24, consisting of 850 pieces of glass, fitted into metal astragals, which were so concealed in the shadows that the whole appeared as one sheet of glass. It contained more than 100 life-size figures, 40 of which were portraits, among which were the two queens, Anne Boleyn, and Cardinal Wolsey. The picture was unfortunately destroyed by fire on the night of June 31, 1832.—ENAMELLED GLASS. Two varieties of enamelled glass, one known as "etched enamelled glass with clear ornaments," and the other as "flocked enamelled glass," are now largely made in Newark, N. J., in the works of Messrs. Cooper and Belcher of New York, the only manufacturers in the United States of the articles in large sheets, and the contractors for the enamelled glass for the New York crystal palace, for which 60,000 feet was furnished. The increasing demand for these beautiful varieties has recently led them to more than double the capacity of their works. The vitreous enamel which gives the opacity to this kind of glass was first devised by John Davenport of Burslem, England, who patented the process in July, 1804. From that time till 1887 the ornamental etching was effected by a tedious and expensive method by hand. Mr. William Cooper, then of Edinburgh, now the

senior partner of the above named firm, in that year secured a patent for a new method of cutting ornamental devices by machinery, &c., on which is based the system now in use. The enamel substance is ground to an impalpable powder, and laid with a brush in a pasty state upon the glass. After the paste is dried, the ornament is etched out by machinery or by hand, and the glass is then softened in the intense heat of the reverberatory furnace till the enamel is vitrified and incorporated with it. From this it is removed to the annealing kiln, the capacity of which is 2,000 or 3,000 superficial feet of large sheets, which is the usual amount of a week's work. The flocked variety of enamelled glass is prepared by the same method as that of the clear etched glass just described, except that a fine, smooth, opaque surface, like satin, much softer and smoother than that of ground glass, is previously given to the whole surface before the enamel is applied. This variety has in great part supplanted the other, and is justly much admired for the softness of the light diffused through it, and for the delicacy and beauty of the elaborate and artistic designs with which it is ornamented. Sheets of it are prepared up to 60 inches in length.—Etching is also applied to the ornamenting of glass, a process which is effected by the property of hydrofluoric acid to eat into the material, as described in the article FLUORINE. The glass is first covered over with a varnish that resists the action of the acid, and when this coating is dry, the lines to be etched are marked through it by means of a point. The acid is then poured on, and is allowed to remain till it has produced the desired effect. The difficulties and danger attending the use of the acid restrict this process to the ornamenting of large polished plates, and to the labelling in indelible letters the bottles of chemists and apothecaries.—GLASS, SOLUBLE, also known by the name of soluble silica, is a preparation of silica and caustic potash, either in equal parts, or in the form of a double silicate of potash and soda, which is soluble in boiling water. Attention was first directed to it by the chemist Von Fuchs as a suitable composition for rendering combustible bodies fire proof; and in 1824 portions of the new theatre in Munich were coated with it. He also employed the composition in the style of fresco painting called stereochromy, as a means of fixing the colors permanently (see FRESCO PAINTING); and it was used not only upon plastered walls, but with perfect success by Echter directly upon the sandstone of the Strasbourg minster. Von Fuchs proposed to render wood fire-proof, and even linen also, by means of it; to protect surfaces from the action of the weather; to prepare with it artificial stone; and to use it as a cement for glass and porcelain. But it appears to have been most successfully applied by Prof. Kuhlmann at Lille, who, as described by Liebig, manufactures it in enormous quantities to prevent the decay of walls and edifices, even when built of

very inferior stone, and for the use of print works and tapestry factories in fixing colors upon cotton and paper. In England also its preparation was early undertaken by Mr. F. Ransome of Ipswich, where many tons of the material are produced every week at the works of the "Patent Silicious Stone Company." Its preparation as a protective coating or as a cement depends on the principle, that when a caustic alkali in combination with silica becomes carbonated by exposure to the atmosphere, the silica is deposited in the pores of the material to which it is applied, and adheres closely to it; or if the stone be calcareous, as marble for instance, a chemical union takes place between the lime and liberated silicic acid. Mr. Ransome, finding this preparation imperfect from the liability of the silica to be washed away by the rains before it could set, applied a second solution consisting of chloride of calcium, which has the effect of causing a silicate of lime of great tenacity and indestructible by atmospheric influences to be immediately produced. His process is as follows: The walls being cleaned, a solution of silicate of soda or potash (the specific gravity of which may be varied to suit the nature of the stone) is applied with a brush; and when dry, the coating is in like manner brushed over with the chloride of calcium solution. The lime immediately combines with the silica, filling the pores of the stone, while the soluble salt of chlorine and soda which is also produced is removed at once by an excess of water. The union of the silica with the stone is found to be as perfect as that of the original particles of the stone itself. The soluble silica is prepared by dissolving carbonate of soda or potash in water, and then rendering the alkali caustic by the use of quicklime. The lime being removed, quartz crushed to powder is dissolved in the liquid in an iron boiler with the aid of steam pressure.

GLASS PAPER, a preparation similar to that of emery paper, made by dusting pulverized glass obtained from the fragments of broken wine bottles upon paper, which is brushed over with thin glue. The glass is first assorted by sifting into lots of different fineness. Instead of paper, thin cotton cloth is sometimes used.

GLASS SNAKE, a North American reptile, improperly called a snake, of the genus *ophisaurus* (Daudin), belonging to the order *sauriphidia* of Gray, and to the chalcidian or cyclo-saurian family of saurians of Duméril and Bibron. The head is lizard-like, sub-oval, with rounded snout, covered above with numerous polygonal plates, large anteriorly, the frontal the largest; the tongue arrow-shaped, triangularly grooved in front, free in its anterior extremity, on which the papillæ are granular; the nostrils are near the snout, lateral, opening upward; the eyes are small, protected by 2 movable unequal lids; there are several rows of short conical teeth, about 86 in number, on the roof of the mouth, chiefly on the pterygoid bones; the intermaxillary teeth are conical, the

maxillary simple and nearly cylindrical, about 40 in all above and 86 below; the external ear is a small oval opening just behind the angle of the mouth. There is no distinct neck; the body is elongated and snake-like, covered with small, smooth, slightly imbricated scales, disposed in circles around the body, about 120 in number; there is no vestige of anterior or posterior limbs externally, and only their rudiments internally; there is a deep groove separating the sides of the body from the abdomen, most visible during respiration, and which doubtless affords the free movement of the ends of the ribs necessary for progression. The tail forms at least $\frac{1}{3}$ of the total length, round, and tapering gradually to the tip, covered with about 140 rings of scales. Though the shape of this reptile is snake-like, the movable lids, external auditory openings, less movable vertebrae, less extensible tongue, rudimentary sternum, and above all the consolidation of the bones of the skull and jaws, sufficiently show its saurian affinities. The length varies from $2\frac{1}{2}$ to $3\frac{1}{2}$ feet. The head above is mottled with black and green, with a yellowish tinge on the jaws; the body and tail above are marked with longitudinal and transverse lines of black, green, and yellow, each scale marked with these 3 colors; the under surface is yellowish, brightest on the abdomen; some slight varieties of color are described. It is found on the Atlantic coast from southern Virginia to Florida, and as far west as the Mississippi, Missouri, and Ohio rivers; it has been seen west of the Alleghenies as far north as Michigan. From the smallness of its gape it cannot destroy and swallow large prey, like the serpents; it cannot climb nor swim, but passes its life on the surface of dry places or in natural cavities in the ground, living principally on mollusks, insects, annelids, and other small animals, and perhaps also partly on vegetable food like the sweet potato. It can move with considerable speed, and is taken uninjured with difficulty on account of the ease with which the joints of the tail are separated; the name of glass snake was given on account of this extreme fragility. The breaking of the tail into small pieces in this and in some scincoid reptiles seems to be the result of a reflex action in the spinal cord, as an irritation of this nervous centre will cause a separation even after the tail is divided from the body. Dr. Barnett ("Proceedings of the Boston Society of Natural History," vol. iv. p. 228) ascertained that the caudal muscles in this reptile do not pass from one vertebra to another, but that a portion are inserted into the skin, while others terminate midway between one vertebra and the next, dovetailed as it were between the fibres sent from that vertebra, and attached to them only by the *myolemma*; so that there is no rupture of muscular fibres, but only a separation of one layer of muscles from the adjoining one, when the tail of the animal is broken; the detached portion is said to be reproduced in a year. The glass snake in its anatomical

peculiarities of structure resembles the chalcidian amphibiaena and the scincoid blindworm (*anguis fragilis*), which see.

GLASSBRENNER, ADOLF, a Berlin humorist, born March 27, 1810. His principal work, *Berlin wie es ist und trinkt*, was published from 1832 to 1850. A new edition of his *Verbotene Lieder* appeared in Berlin in 1851, and of his *Neuer Reineke Fuchs* in 1854. His racy delineations of life, some of which have appeared under his *nom de plume* of Brennglas, have become very popular, especially in Berlin. Banished from that city in 1850 on account of his sympathies with the democratic party, he has since chiefly resided in Hamburg.

GLASSITES, a religious sect in Scotland, whose founder was John Glass (1695-1773), a minister of the Scottish established church, who was deposed in 1728 for avowing opinions adverse to all legal establishments of religion. Robert Sandeman advocated the same opinions about the middle of the century, from whom the sect is sometimes called Sandemanians. They hold peculiar views of justifying faith and ecclesiastical polity, maintaining a spiritual union of their members which is not represented by any visible church. They observe also certain practices which they suppose to have been prevalent among the early Christians, as love feasts, washing of each other's feet, plurality of elders, and mutual exhortations. In 1851 there were 12 Glassite congregations, with accommodations for about 2,000 persons.

GLASTONBURY, a market town and parish of Somerset, England, 25 m. S. W. from Bath; pop. in 1851, 3,125. The town occupies an eminence nearly surrounded by marshy flats, and derives its interest and importance almost wholly from its ruins, prominent among which are those of a famous Benedictine abbey, founded, it is said, by St. Augustin in 605, rebuilt in great splendor about a century later, and enriched by the liberality of successive princes until the time of Ethelred I. It suffered from the Danes, and before the conquest, when the Normans robbed it of both wealth and influence, had gained considerable importance and celebrity. Its half ruined walls were rebuilt by Stephen and Henry II., and its abbot was honored with a mitre and a seat among the barons in parliament. At one time it was annexed to the see of Wells, the incumbent of which was called bishop of Glastonbury. On the suppression of monasteries by Henry VIII. it enjoyed a revenue of £3,508 13s. 4d. In 1539 Richard Whiting, the last abbot, for refusing to surrender the abbey to the king, was hanged in his robes on Torhill with two of his monks. The abbey ruins, consisting of portions of the church, the chapel of St. Joseph of Arimathea, and a building called the abbot's kitchen, are comprised in a quadrangle of 60 acres, which was once encompassed by a high wall. A reputation for sanctity clung to Glastonbury long after the reformation, and as late as 1751 we hear of 10,000 invalids flocking hither in a sin-

gle month to drink from a spring said to have wrought miraculous cures. A work on the efficacy of these waters, entitled "Wilt thou be made Whole?" was published at Bath in 1751.

GLATZ, a county, circle, and town in the Prussian province of Silesia. The county comprises the circles of Glatz and Habelschwert in the district of Breslau; pop. 144,000. It forms a broad and uneven valley, surrounded by mountains, which separate it from Bohemia and Austrian Silesia, and is watered by the Neisse and its affluents. The soil in the vales is fertile, and on the mountain sides is favorable for grazing. There are mineral springs and coal mines, and flourishing linen and cotton manufactories. The possession of the county was long in dispute between Poland and Bohemia, and it frequently changed masters till conquered with Silesia by Frederic the Great; it was finally ceded to Prussia by the peace of Hubertsburg (1763).—The town is situated on the left side of the Neisse, and is strongly fortified, being defended by an old citadel, a modern fortress, and other works; pop. 10,650. It has a Roman Catholic gymnasium and college, a hospital, infirmary, barracks, and several factories. It was fortified as early as the 11th century, and has sustained numerous sieges. It capitulated in 1622 to the imperial troops, and in 1742 to the Prussians.—A part of the Sudetic mountains is often designated by the name of Glatzer Gebirge.

GLAUBER, JOHANN RUDOLF, a German chemist, born in Karlstadt in 1604, died in Amsterdam in 1668. He was a physician and alchemist, boasted of possessing several wonderful secrets, and was called the Paracelsus of his age. He passed his life in his laboratory, successively at Salzburg, Frankfurt, Cologne, and Amsterdam, and first exhibited the production of artificial salts, and discovered the salt to which his name is given. He wrote voluminously both on chemistry and alchemy, and a collection of his works were translated into English by C. Packe (London, 1689).

GLAUBER'S SALT, sulphate of soda, found native and artificially produced. The artificial salt was named from its discoverer (see above), who obtained it in making muriatic acid. The natural salt is usually met with as an efflorescence, sometimes deposited around hot springs, as at Carlsbad and Cheltenham, or about saline ponds, as in the country between the head waters of the Arkansas and Santa Fé, on the route to the Rocky mountains. It also occurs in a cavern near a volcano on Hawaii, one of the Sandwich islands, where it is produced by the action of the volcanic heat and gases upon the sea water. It is found as an efflorescence on the limestone rocks below the Genesee falls, Rochester, N. Y. It crystallizes in forms derived from an oblique rhombic prism. The crystals effloresce in the air, and lose their water of crystallization. It is most soluble in water at the temperature of 98.2° F., when, according to the experiments of Löwel, 412.22 parts of the

hydrated salt are dissolved by 100 of water; at 77° only 98.48 parts are taken up, and at 68°, 58.85 parts. The salt has a taste cool at first, then saline and bitter. It is white, transparent to opaque, of vitreous lustre, of hardness from 1.5 to 2, and specific gravity 1.481. Its composition is represented by the formula $\text{NaO}, \text{SO}_3 + 10\text{HO}$, making its equivalent 161, and the percentage of water 55.76. It is artificially prepared by decomposing common salt by sulphuric acid (as in the preparation of hydrochloric acid, of which process it is the residue), with an excess of acid, which is taken up by the addition of carbonate of lime. It is very largely manufactured in England and France in order to prepare from it carbonate of soda and soda ash; to avoid the production of muriatic acid, a process has been introduced of making the salt by the reaction of common salt and sulphate of iron upon each other. It is also obtained as a residuum in the manufacture of bleaching salts, muriate of ammonia, &c., and from sea water, by exposing the water to intense cold, when this, the least soluble salt, separates by crystallizing.—Sulphate of soda is principally of value as a medium for obtaining the other salts of soda. Formerly it was much used in medicine as an aperient and diuretic; but sulphate of magnesia has taken its place, though it is still an ingredient in Seidlitz powders. By dissolving it in hydrochloric or dilute sulphuric acid, cold is produced, by which water may be frozen in summer; and wine coolers have been made designed for its use, in which, with 12 lbs. of the salt and 10 lbs. of acid, 10 to 12 lbs. of ice have been formed in the course of an hour. (See FREEZING MIXTURES.) The salt is an ingredient in some kinds of glass.

GLEE (Sax. *glia*, from *glig*, *gligg*, sport, music), a vocal composition in 8 or more parts, which is generally performed without instrumental accompaniment. Gleees have for nearly 8 centuries formed a favorite musical recreation in England, although the term itself was not in use previous to the latter part of the 17th century.

GLEIG, GEORGE, a Scottish bishop and writer, born in Boghall, Kincardineshire, May 12, 1758, died in Stirling in Feb. 1889. He was educated at the university of Aberdeen, took orders in the Episcopal church, became in his 21st year pastor of a congregation at Pittenween, in Fifeshire, and was raised to the bishopric of Brechin in 1808. He was through life devoted to literature, was active in obtaining the repeal of the penal laws against the Episcopalians of Scotland, and edited the later volumes of the 3d edition of the "Encyclopædia Britannica," and wrote almost without assistance the 2 supplementary volumes. He is also the author of occasional sermons, and of "Directions for the Study of Theology" (London, 1827).

GLEIG, GEORGE ROBERT, son of the preceding, a Scottish clergyman and author, born in Stirling, April 20, 1796. He abandoned his studies at Oxford to join as a volunteer a regiment

going to Spain in 1818, and served both in the Peninsula and in America. On retiring from the army he resumed his studies at Oxford, took his degree, was ordained, and was subsequently appointed chaplain to Chelsea hospital, and in 1846 chaplain general to the forces. His exertions to establish a system of education for the soldiers have since gained for him the inspector-generalship of military schools. The works of Mr. Gleig are for the most part histories or novels. Of the former, the "Family History of England" (1836; 2d ed. 1854) and the "Military History of Great Britain" (1845) are most esteemed; and of the latter, the "Subaltern" (1835), "Chelsea Pensioners" (1829), and "Country Curate" (1834). His eulogistic "Memoir of Warren Hastings" (1841) has been severely criticized. In 1858 he collected 2 vols. of his "Essays," chiefly from the "Edinburgh" and "Quarterly" reviews.

GLEIM, JOHANN WILHELM LUDWIG, a German poet, born in Ermsleben, Prussia, April 2, 1719, died in Halberstadt, Feb. 18, 1803. He published odes, fables, tales, and songs, which obtained for him the title of the German Anacreon. One of his best fables is *Die Grille und die Ameise*. He was an enthusiastic admirer of Frederic the Great, and his best productions celebrated his exploits. His *Siegeslied nach der Schlacht bei Rossbach* is the most famous of his battle songs. Gleim was very popular in Germany, and exercised for about 40 years a master influence on literature, less by his genius than by his generous patronage of young authors. He was a bachelor, but his home, kept by his accomplished niece Sophia Dorothea Gleim (whom he celebrated in his songs under the name of Gleminde), was a favorite resort of the most eminent German poets and scholars. An edition of his works, which appeared in 7 vols. in Halberstadt (1811-'18), was completed by an 8th vol. (Leipzig, 1842).

GLENCOE, one of the wildest and most gloomy of the Scottish glens, in the district of Lorn, Argyleshire, about 10 m. in length, and enclosed by lofty mountains. The lower part of the glen near Loch Leven is cultivated and wooded, but the upper part is exceedingly rugged and barren, the mountains rising almost perpendicularly in fantastic forms, seamed with deep furrows worn by the winter torrents. A small lake, from which issues the Cona, lies in the middle of the valley. The path through the glen is lined by immense masses of rock. Near its N.W. extremity is the scene of the "massacre of Glencoe." After the revolution of 1688 many of the Scottish clans continued in arms for King James against King William. In Aug. 1691, the government of William issued a proclamation offering an amnesty to such insurgents as should take the oath of allegiance on or before Dec. 31. All the chiefs submitted within the prescribed time except the aged Maclean or Macdonald of Glencoe, whose tribe, a few hundred in number, inhabited this secluded valley. He went, Dec. 31, to Fort William and offered to take the oath; but the

colonel in command, not being a magistrate, could not administer the oath, and referred the chief to the sheriff at Inverary. Macdonald made his way to that place as speedily as possible over rugged mountains covered with snow, and took the oath of allegiance on Jan. 6, 1692. Three great Scottish nobles, the earls of Breadalbane and Argyle, and the master of Stair, who were then in London, determined to avail themselves of this unintentional delay to effect the destruction of the tribe of Macdonald, to whom Argyle and Breadalbane were hereditary enemies. The master of Stair was secretary of state for Scotland, and by representing to William that Glencoe had not submitted, and that the dwellers in the valley, whom he described as a band of robbers, were the only remaining obstacle to the complete pacification of the highlands, he obtained from the king an order for their extirpation. It was executed with horrible treachery and cruelty. On Feb. 1 a body of soldiers, 120 in number, commanded by Campbell of Glenlyon, were sent to occupy Glencoe. They came professing peace and friendship, were received with the kindest hospitality, and for a fortnight lived at free quarters in the utmost familiarity with the people. On the evening of Feb. 12 the officers supped at Macdonald's house, and played cards with himself and his family. That same night, one of these officers, Lieut. Lindsay, with a party of soldiers, returned to the old chief's house, knocked, and was admitted. Macdonald rose from his bed to receive them, and was calling to his servants to bring refreshments for his visitors when he was shot through the head. His wife received such barbarous usage that she died the next day. Two of his attendants were also murdered. The commanding officer, Glenlyon, lodged in the house of a sub-chief, Inverriggen. At 5 in the morning the highlander and 9 of his family, among them a boy of 12 years old, were dragged from their beds and murdered in cold blood. At another house 8 persons sitting at breakfast were shot dead. In all, 40 persons were killed, among them several women. It was the intention of the butchers to slaughter the whole tribe, but owing to the inclemency of the night a detachment of soldiers sent to guard the outlets from the valley did not arrive in season, and the greater part of the people, aroused by the report of the fire-arms, fled naked to the mountains, where many of the women and children perished with cold and hunger. No punishment was inflicted on the authors of this crime. A graphic account of the massacre of Glencoe is given by Macaulay in his "History of England," vol. iv., and Campbell has made it the subject of a poem, "The Pilgrim of Glencoe." A writer in "Blackwood's Magazine," July, 1859, accuses Macaulay of partiality in his account of Glencoe, and charges the responsibility of the massacre on William III., acquitting him, however, of any intention of sanctioning treachery and breach of hospitality.

GLENDOWER, or GLENDWR, OWEN, a Welsh

chieftain, born in Merionethshire about 1849, died Sept. 20, 1415. His father was Gryffydd Vychan, and his mother, Elena, was granddaughter of Llewellyn, the last Welsh prince of Wales. He studied law at the inns of court in London, and became a barrister, but soon quitted the profession for that of arms. He was made squire of the body to Richard II., to whom he adhered to the last of his disastrous reign. In 1387 he was knighted, and at an early age married Margaret, daughter of Sir David Hanmer. After the deposition of Richard II., he retired to his lordship of Glendwrddwy in Wales. His retirement was wrongfully construed into disloyalty to the new king Henry IV., and his estates were declared forfeited, and seized by Lord Grey de Ruthyn, an Anglo-Norman nobleman whose domains adjoined those of Glendower. Thus driven into rebellion, Glendower proclaimed himself prince of Wales, and called his countrymen to arms. The Welsh bards, who hated the English, by whom they were persecuted and treated as vagabonds, espoused with ardor the pretensions of Glendower, to whom they attributed supernatural and necromantic powers, and whose fame they spread so rapidly that he was soon at the head of a considerable force of enthusiastic partisans. In the summer of 1400 he invaded and seized upon the estates of Lord Grey. That nobleman in reprisal, with the help of Lord Talbot, who had been sent to his assistance by the king, surprised and captured the residence of Glendower, who narrowly escaped being made prisoner. Rallying his followers, he pillaged and burned the town of Ruthyn, and made such progress that the king in person took the field against him. A long contest ensued, in the course of which Glendower, in 1402, made prisoner his old enemy, Lord Grey, who was compelled to pay a ransom of 10,000 marks, and to marry Jane, the 4th daughter of the Welsh chieftain. He next destroyed the cathedral of Bangor, and the cathedral and palace of St. Asaph, defeated Sir Edmund Mortimer at Pilleth Hill, near Knighton, in Radnorshire, with a loss of 1,000 men, took Sir Edmund prisoner, and treated him with such kindness that he became Glendower's partisan, and arranged for him an alliance with the Percys of Northumberland. The confederates agreed to divide the kingdom among themselves. The earl of Northumberland was to have all north of the Trent; Glendower all west of the Severn; and Mortimer, in the name of his nephew Edward Mortimer, the rightful heir to the crown, was to have the rest. Glendower, who was now at the height of his power, called together the estates of Wales, and was formally crowned prince at Machyulleth. In 1403 the confederates gave battle to Henry near Shrewsbury, and were defeated, Percy being killed in the action. In 1404 Glendower entered into an alliance offensive and defensive with Charles VI. of France. He gained some victories, but in March, 1405, he was defeated with the loss of 800 men at

Grosmont castle, and a second time in the same month at Mynydd pwl Melyn, with a loss of 1,500. For a time he wandered a fugitive through Wales, concealing himself in woods and caves. The French king, however, sent him a reinforcement of 12,000 men, to whom Glendower joined 11,000 Welsh, and marching into England, penetrated as far as Worcester. Here several indecisive engagements took place, and at length the French and Welsh allies retreated into Wales, and shortly afterward the French returned to their own country. For some years Glendower, protected by his mountains and forests, waged a partisan and predatory war with varying success, and at the time of his death was negotiating with Sir Gilbert Talbot, who had been sent by Henry V. to offer Glendower and his followers a free pardon on condition of returning to their allegiance. Glendower had 5 daughters and several sons, most or all of whom fell in battle in 1400.

GLENTWORTH, GEORGE, an American physician and surgeon, born in Philadelphia, July 22, 1785, died there, Nov. 4, 1792. After visiting various parts of Europe in 1755, he was graduated at the university of Edinburgh in 1758. He became a junior surgeon in the British army during the last French war in America. In 1777 he relinquished an extensive practice, and became first a regimental surgeon, and afterward senior surgeon, in the American army. In this capacity he extracted the ball received by Lafayette at the battle of Brandywine. Subsequently he was appointed director-general of hospitals for the middle division.

GLIDDON, GEORGE ROBERT, an English Egyptologist, born in Devonshire in 1809, died in Panama, Nov. 16, 1857. He went at an early age to Alexandria, where his father was a merchant, and also U. S. consul. He resided in Egypt 28 years, and was during part of the time U. S. vice-consul at Cairo. After leaving Egypt he came to the United States, and lectured at Boston, New York, and Philadelphia, on Egyptian antiquities. At the time of his death he was agent for the Honduras inter-oceanic railway company. He was the author of the following works: "Appeal to the Antiquaries of Europe on the Destruction of the Monuments of Egypt" (1841); "Discourses on Egyptian Archaeology" (8vo., London, 1841); "Oria Egyptiaca" (1849); "Ancient Egypt" (1 vol. 4to., London and Philadelphia, 1850; new ed., 8vo., London, 1853); "Types of Mankind," written in conjunction with Dr. J. O. Nott and others (Philadelphia, 1854); "Indigenous Races of the Earth," also partly written by Dr. Nott and others (8vo., Philadelphia, 1857).

GLINKA, the name of a Russian family, to which the following literary men, all natives of the government of Smolensk, belong: I. GZEOZI, born in 1774, died in Moscow in 1818, served as page at the imperial court and as an officer in the army, held various civil offices, officiated as teacher of the Russian language at the university of Dorpat, and accompanied the

grand dukes Nicholas and Michael on their travels in Russia and abroad. He wrote "The Ancient Religion of the Slavi" (1804) and various minor works, and translated a number of French and German books, chiefly on historical subjects. II. *Сумароков*, born in 1774, died in Moscow in 1847, served in the army, which he left in 1799 with the rank of major, and was engaged as teacher in the Ukraine and at Moscow. Among his works are: "Natalia," a drama (1805); a translation of Young's "Night Thoughts" (1806); "Prince Michael of Tchernigov," a tragedy (1807); "Fair Olga," an opera (1808); "History of Russia for Young People" (10 vols., 1817 *et seq.*). He also edited the "Russian Messenger" from 1808 to 1821, and an autobiography of Suwaroff (1819). III. *Фадор*, born in 1788, served in the Austrian campaign of 1805 against Napoleon, and during the invasion of Russia in 1812, became colonel, was accused of being a member of secret societies and sent to Petrosavodsk in the government of Olonetz, and became after his return to the capital president of the "Society of Friends of Russian Literature." He is highly esteemed both as a poet and as a military historian, his chief productions being "Letters on the Campaigns of 1805-'6 and of 1812-'15" (8 vols., 1815 *et seq.*), historical novels, and poetical translations from the Bible. IV. *Михаил*, born in 1804, died in Berlin in 1857, was the author of various national Russian operas, and became the director of the imperial opera as well as of the choir of the imperial chapel at St. Petersburg.

GLOBE, ARTIFICIAL, a hollow sphere of sheet metal, plaster, pasteboard, paper, or other material, upon the surface of which is delineated a map of the earth or heavens, with the various circles to which points are referred to determine their positions. Globes are thus of two sorts, severally called terrestrial and celestial. They serve as models to impart correct ideas of the form and movements of the earth and of the heavenly bodies, of their position in relation to each other at different times, also of the relative positions of places upon the earth, and of the principle of designating these by lines of latitude and longitude. Globes are also applied to the mechanical solution of various astronomical problems, as the difference of time in different places, dependent on the position of the sun in relation to those places, the times of the rising and setting of the sun at any place, and many other similar questions, which may be approximately determined without recourse to mathematical calculations. It is however chiefly for the sake of the clear instruction in general geography, which many persons fail to derive from maps, that globes are especially valuable. It is unknown when they were first constructed; but the first terrestrial globe is supposed to have been made by Anaximander of Miletus, a pupil of Thales, who flourished about 600 B. C. Ptolemy made use of one provided with the universal meridian, such as is applied to those now in use. The ancients are also said

to have had celestial globes. Martin Behaim, the celebrated navigator, constructed a terrestrial globe at Nuremberg toward the close of the 15th century. Tycho Brahe had one of copper nearly 5 feet in diameter. Another was made in Venice in 1683 for Louis XIV., 12 feet in diameter. Another, 11 feet in diameter, constructed by Brousch of Limburg, attracted the attention of Peter the Great, who caused it to be purchased and removed to St. Petersburg. It was large enough to accommodate 12 persons sitting around a table within it. Its inner surface was celestial, the stars being represented by gilded nails; and the outer surface was terrestrial. The imperial library of Paris has 2 globes of over 14 feet diameter. A magnificent copper globe made for Louis XVI. is in the Mazarin library; and another of the same material and of admirable workmanship, designed by Poirson, for the instruction of the king of Rome, and bought by Louis XVIII. for 86,000 francs, is in the museum of the Louvre. In 1851 a globe of mammoth dimensions and novel construction was built in Leicester square, London, by Mr. Wyld. It was 56 feet in diameter, and the delineations were upon the inside only. These were modelled in slabs of plaster of Paris, which were set like a ceiling on the ribs of zinc which formed the framework of the structure. The slabs were cast in clay moulds, which were prepared with care from the most correct maps on a scale of 10 miles to the inch. About 6,000 slabs were required to cover the whole surface, their dimensions varying from 2 feet square as the width diminished toward the poles. The topographical features were represented in relief, and the surface finally painted in colors. A stairway wound around from the base by which the circular platforms one above another were reached that brought the spectators near to the inner surface of the great shell. —The globes used by geographers in the middle of the last century were very similar in their details to those now in use. Much attention was directed to their manufacture, and a treatise on their construction and use was published in 1769 by Mr. George Adams, mathematical instrument maker to his Britannic majesty. The first requisite is a ball to receive precisely the printed map; this is therefore first accurately measured, and due allowance is made for the shrinking each segment will experience after being wet. The diameter being determined, a silver-steel semicircle $1\frac{1}{2}$ inches wide and $\frac{3}{4}$ inch thick is next made, of precisely half this diameter less that of the wires intended for the poles. A globe of wood is now made $\frac{2}{3}$ of an inch less in diameter than the steel circle. Into 2 opposite points of this so called mould bits of No. 7 wire are inserted for poles. Dry paper is laid all over it to prevent the pasted paper to be next laid from adhering. This is of coarse heavy quality, and some 8 or 10 layers saturated with paste are applied in succession as evenly as possible, covering the whole surface. As this coating becomes dry, it shrinks and fits tightly

over the mould. It is then hung by the poles in the front edge of a bench fitted to receive it, and by applying a knife on the line of the equator while the ball is made to revolve, the shell is cut through, so that it may be taken off the mould in two hemispheres. This being done, a turned stick of right length with a short wire in each end for poles is introduced, one end in each hemisphere, and the two shells being brought together are secured by glueing their edges. The ball, called in its present state the foundation, is placed in the steel semicircle, and coated with a composition of glue and whiting. Being made to revolve, the excess of the composition is removed by the circle, and the ball is thus turned smooth and true, after which it is carefully dried. The next process is to lay out the lines of latitude and longitude, which is done by a beam compass, commencing with the colures and ecliptic. The first meridian is usually made to pass through the intersections of the equator and ecliptic, the points of the vernal and autumnal equinoxes; and from the former of these points the reckoning of the degrees on the equator and ecliptic begins. The maps are now to be cut on the engraved meridians of each 15° , thus making 24 segments; and these are pasted in succession with white paste upon the foundation, the lines drawn upon it serving as guides. The fitting requires great care, that the edges may be made to exactly coincide, and some stretching of the equatorial portions is sometimes requisite. When dry the paper covering is colored, and then sized with gelatine and immediately varnished. The final process before mounting is to dry again at 200°F . Holtzapffell says: "A globe is usually covered with 26 pieces of paper, namely, 2 pole papers or circles, including 30° around each pole, and 24 gores meeting at the equator. Sometimes the gores extend from the pole to the equator; every gore has then a narrow curved central notch extending 30° from the equator." The globe is hung for support by its poles in a brass circle, which goes round it and is called the universal meridian, inasmuch as any point upon the surface of the globe revolving in this may be brought under it. It is divided into degrees, which on one side are reckoned from either pole toward the equator for the purpose of giving the elevation of the poles, and on the other from the equator toward either pole, to be used for finding the latitude of places. A frame or stand is prepared to receive the globe with its brass circle, the top presenting a broad horizontal circle with two vertical slots placed opposite each other for receiving the brass meridian; which when adjusted is free to slide around in its own plane, so that the poles may be upright, horizontal, or at any angle to the horizontal circle. Around this circle, which represents the rational horizon or imaginary plane passing through the centre of the earth, are drawn several concentric circles; the innermost represents the horizon, and the slots for the brass circle are on the N. and S. points; the

degrees on the northern 2 quadrants are reckoned from E. and W. toward the N., and those on the southern toward the S. Outside of this is the circle representing the calendar, with the names of the months and divisions corresponding to the days. The next circle contains the signs and degrees of the ecliptic, so arranged that against each day of the year is found the point of the ecliptic in which the sun is situated. In the globes recently constructed by Messrs. Moore and Nims of Troy, N. Y., the horizontal circle is made to revolve. It is attached to arms which extend below the brass meridian, and unite, supporting the adjusting clamp, which supports the brass meridian. A taper pin extends down 3 inches from the lowest part of the arms and fits into a socket in the iron base, thus securing by the revolutions of the meridian and horizon in their own planes the effect of a universal joint, so that any part of the globe can be brought under observation without changing the position of the base. Upon the N. pole of the globe is attached a small circle of brass, called the hour circle, the pole passing through its centre, and holding it so that the two move round together, but yet admitting the hour circle to be moved round by the hand upon the axis. The circle is divided into 24 equal parts, corresponding to the hours of the day, and either one of these can be placed upon any meridian by turning the circle. The quadrant of altitude is a brass slip equal in length to $\frac{1}{2}$ the circumference, and divided into 90° . It is fastened to the brass meridian, and is used for measuring degrees in any direction on the globe. A mariner's compass is sometimes attached to the frame of the globe for the purpose of placing the meridian in a N. and S. line. The various circles connected with the terrestrial globe are equally appropriate to the celestial; and as the latter are ordinarily constructed, the observer is supposed to be looking down upon the heavens presenting a convex surface, upon which the stars and constellations are mapped in their proper relative positions. To render the nature of the imaginary circles to which the points upon both globes are referred more clear for the student, the armillary sphere was contrived, which consists of the several circles in the form of graduated brass rings placed in their appropriate positions, and containing in the centre a small globe representing the earth. These circles are the horizon, meridian, equator, ecliptic, equinoctial colure, and the solstitial colure. The sphere formed by them is supported in a frame in the same manner as the globes.—To render the principles taught by globes more familiar and intelligible to students, these instruments were constructed many years since in England with blank surfaces, or at least with nothing more than the meridians and parallels of latitude drawn upon them. They were covered with a substance on which drawings could be made with a slate pencil and easily effaced. White globes were also in use

in the United States 30 years ago, adapted for similar practice with the lead pencil. The so called blank slate globes recently introduced are of the same character. The globes of Messrs. Blunt of New York have on them isothermal lines and deep sea soundings.

GLOGAU, a circle in the Prussian district of Liegnitz, formed of part of the former principality of Glogau in Lower Silesia; pop. 72,800.

—GLOGAU, or GROSS-GLOGAU, the capital of the district, is situated on the left bank of the Oder, 44½ m. by rail from Berlin, and 175 m. from Breslau; pop. 16,200. It is strongly fortified, and contains an old castle, 4 churches, a Protestant and a Roman Catholic gymnasium, extensive barracks, several hospitals, and various manufacturing factories. It is connected by a bridge with an island in the Oder, on which stand the cathedral and a strong fortress.

GLOMMEN, a river of Norway, rising in the mountains of the E. part of the province of Dronheim, in lat. 63° N., and flowing for the most part nearly due S., through several lakes, into the Skager Rack. Its length is about 360 m. The entire valley through which it flows is remarkable for picturesque scenery, cataracts, and forests of pine, producing the finest timber in Europe. From the town of Røraas to the Oieren lake, the river is a mountain torrent. The head of navigation is at Sarpsborg, about 10 m. above Frederikstad, which stands at the mouth of the river. About half a mile above Sarpsborg is the famous cataract of the Glommen, known as Sarpfoss. The river, a short distance above, is divided into two branches, which flow in parallel directions to the sea. The E. branch, having forced its way through a rugged defile, reaches the brink of a precipice, where, although divided at the summit by a projecting cliff, it falls an unbroken and perpendicular cascade, about 75 feet. The abyss is strown with large masses of granite, which break the volume of water into vast sheets of foam. On the brink of the fall, the stream is about 120 feet wide, and from 26 to 30 feet deep, according to the season. The rapids, for a short distance inward, are remarkably fine, but before reaching Sarpsborg the river has again become a smooth-flowing stream, and preserves this character for the remainder of its course.

GLONOINE, a compound of oxide of glycol with nitrous acid, obtained in the form of a heavy yellow oil by the action of nitro-sulphuric acid upon glycerine. The glycerine in sirup is slowly added to a mixture of 2 parts by measure of sulphuric acid, sp. gr. 1.838, and 1 part of nitric acid, sp. gr. 1.48, surrounded by a freezing mixture. The ingredients should be kept in constant agitation. By adding water the glonoine is precipitated, and may then be separated, dissolved in alcohol, and precipitated from this in a pure state. It is a sweet, aromatic, and pungent substance, remarkable for its action upon the animal system, the smallest quantity placed upon the tongue producing violent headache, and exceedingly minute doses

when swallowed being followed by giddiness, a sense of fullness and pressure in the frontal region, and headache. When a single drop is mixed with 5,000 globules of milk sugar, the peculiar effects of the substance are experienced by some persons on taking only 5 of these globules. Most persons are thus affected by 20 of the globules or $\frac{1}{10}$ of a grain. A cat has been destroyed by a dose of 4 drops, and another by 3 drops. The largest dose taken by a man has been $\frac{1}{10}$ of a drop. Coffee is found to be an antidote to the effects of a large dose. The name given to the compound is made from the symbols of its ingredients, with the termination *ine*.

GLOUCESTER. I. A S. W. co. of N. Jersey, separated by the Delaware river from Penn. on the N. W., drained by Big Timber, Oldman's, Raccoon, and Mantua creeks; area, 280 sq. m.; pop. in 1855, 16,261. The surface is generally level, and much of it covered with forests. The soil along the banks of the Delaware and for about 7 m. inland consists of a clayey loam, productive, and well cultivated. Marl is found here, and iron ore is obtained near Woodbury. The S. E. part of the county is sandy and mostly unimproved. The productions in 1850 were 880,221 bushels of Indian corn, 59,037 of wheat, 11,886 of oats, 258,964 of potatoes, 254,870 of sweet potatoes (the greatest quantity produced in any county of the state), 14,152 tons of hay, and 257,022 lbs. of butter. There were 19 corn and flour mills, 14 saw mills, 1 woollen and 4 glass factories, 1 newspaper office, 26 churches, and 3,656 pupils attending public schools. Organized in 1677, and named from Gloucestershire, England. Capital, Woodbury. II. A S. E. co. of Va., bordering on Chesapeake bay, bounded N. by the Piankatank, and S. W. by York river; area, about 280 sq. m.; pop. in 1850, 10,527, of whom 5,557 were slaves. The surface is level, and the soil light and productive. Among the most important exports are oysters and fish, the taking of which employs large numbers of the inhabitants, and wood, which is sent to New York and Philadelphia. The agricultural products in 1850 were 836,068 bushels of Indian corn, 65,551 of wheat, 11,934 lbs. of wool, 575 of tobacco, and 62 bales of cotton. There were 16 corn and flour mills, 8 saw mills, 2 tanneries, 14 churches, and 258 pupils attending public schools. Value of real estate in 1850, \$1,297,432; in 1856, \$1,879,792, showing an increase of 45 per cent. The county was formed in 1642. Capital, Gloucester Court House.

GLOUCESTER, a N. E. co. of New Brunswick, bounded N. by the bay of Chaleur, W. by the gulf of St. Lawrence, and drained by Nipisiquit, Cawaquette, Pohamoeche, and Tracadie rivers; area, 1,250 sq. m.; pop. in 1851, 11,704. The surface inland is diversified by hills, between which lie fertile valleys. The climate is favorable for agriculture, while the great extent of coast, off which are several islands, and the number of good harbors, afford opportunities for fishing and lumbering. Ship-building is actively carried on. Capital, Bathurst.

GLOUCESTER, a town and seaport of Essex co., Mass., on the S. side of the peninsula of Cape Ann, 28 m. N. N. E. of Boston; pop. in 1850, 7,808; in 1855, 8,935; in 1859, estimated at 12,000. Gloucester formerly comprised the whole of Cape Ann, and was 8 m. long by 5 broad; but in 1840 the E. portion of the peninsula was formed into the town of Rockport. The Indian name of Gloucester was Wingaersheek. It was occupied as a fishing station in 1624, and was the first place settled by the English on the N. side of Massachusetts bay. In 1642 it was incorporated under the name of Gloucester, some of the principal inhabitants having come from Gloucester, England. In 1692, a year of great spiritual commotion in New England, the people of the town fancied themselves infested by armed Frenchmen and Indians, who were frequently seen and fired at, and who in return fired at the inhabitants, though without effect. The alarm continued for 8 weeks, and several hundred men were kept under arms. It was finally concluded that these "unaccountable troublers" were spectral visitants, and the clergyman of the town, the Rev. John Emerson, expressed it as his opinion that "all rational persons will be satisfied that Gloucester was not alarmed for a fortnight together by Frenchmen and Indians, but that the devil and his agents were the cause of all that befell the town." A more tangible enemy, the British sloop-of-war Falcon, Capt. Linzee, assailed the town, Aug. 8, 1775, bombarded it for several hours, and attempted to cut out some vessels in the harbor. The people made a gallant resistance, and killed, wounded, or captured nearly half the Falcon's crew, and all her boats except a small skiff. In the second war with Great Britain, Sept. 8, 1814, Gloucester was attacked by the British frigate *Tenedos*, which, however, did no serious damage, but lost a barge and 18 men in the contest. In both of these wars the town sent out swarms of privateers, and contributed largely to the manning of the U. S. navy.—There are 4 distinct villages in the town of Gloucester: Sandy Bay, at the E. extremity of the cape, where a pier and breakwater have been constructed for the protection of shipping; Annisquam, or Squam, on the N. side of the cape, which has a safe harbor much resorted to by fishing vessels, and a beach 2 or 3 m. long, of white sand, of which large quantities are carried away and sold; West Parish, in which there is an ancient church, one of the oldest in New England, situated on a high hill, with a fine view of the sea; and lastly, Gloucester village, or "The Harbor," which has one of the best ports on the coast, capacious, safe, easy of access, and with sufficient depth of water to admit the largest vessels. The village is handsomely and compactly built, and is very beautifully situated, with extensive and picturesque sea views. Of late years it has become a fashionable summer resort for bathing and sea air, and several fine hotels have recently been erected. It is the first fishing town in the United States, and

the third in Massachusetts in foreign commerce. It has considerable trade with Surinam. In 1856 there were 203 arrivals from foreign ports; 18 ships and 320 schooners were owned in the place, tonnage 30,744. The fishing business employs a capital of about \$1,500,000. In 1859 the number of fishing vessels was 357 and the number of fishermen 8,890. In 1855, 43,201 barrels of mackerel were taken, worth \$388,809; the value of codfish taken was \$293,850. In 1857, 64,599 barrels of mackerel were taken, and in 1858, 64,562. In 1855 the value of the manufactures and other products of Gloucester was as follows: bar iron, anchors, cables, &c., \$50,800; sails, \$95,250; oil, \$18,035; soap and candles, \$11,480; boots and shoes, \$32,175; building stone (granite), \$75,000; bread, \$69,500; ice, \$15,000; coffee burnt and ground, \$30,000. Gloucester contains 11 churches; and 3 newspapers are published weekly, one of them also semi-weekly. There are 2 banks and a savings institution, 2 marine insurance companies, and a gas-light company. A branch of the eastern railroad connects the town with Boston.

GLOUCESTER, a city and municipal and parliamentary borough of England, capital of Gloucestershire, on the left bank of the Severn, 114 m. by rail N. W. from London; pop. in 1851, 17,572. The chief public edifices are the cathedral, which grew up from a monastery between the 7th and 15th centuries, several handsome parish churches, a college, blue coat and free grammar schools, the county hall, hospitals, &c. The college school was founded in 1536; the free grammar school, founded in 1539, has an income of £30 a year, and 2 exhibitions of £50 a year each to Pembroke college, Oxford; and the blue coat school, founded in 1666, and superintended by the corporation, supports, educates, and apprentices 20 poor boys. The handsomest portion of the town is at the S. end, around a spring of saline chalybeate water discovered in 1814. The staple manufactures are pins, hardware, bells, gloves, saddles, canvas, ropes, and soap. A bell foundry was established prior to 1500. Since the completion in 1827 of the Berkeley ship canal, by which vessels of 500 tons burden can come up to the city, the commercial importance of Gloucester has greatly increased. The city is probably of British origin. It became a Roman station under the name of Colonia Glevum, and under Claudius, received the name of Claudia Castra. The Saxons called it Glean-ceaster, and it flourished during the heptarchy. In the 17th century it was strongly fortified, and took a conspicuous part against the royalists. It is governed by a mayor, 6 aldermen, and 18 councillors, and returns 2 members to parliament.

GLOUCESTERSHIRE, an inland co. of England, bounded N. by Worcestershire and Warwickshire, E. by Oxfordshire, S. E. by Berkshire, S. by Wiltshire and Somersetshire, and W. by Monmouthshire and Herefordshire; area, about 1,258 sq. m.; pop. in 1851, 458,805. It is traversed from N. E. to S. W. by the Cotswold

hills, which separate the basin of the Severn from that of the Thames. The district between these hills and the Severn comprises the vales of Evesham, Gloucester, and Berkeley, of surpassing beauty and richness. Beyond the Severn the greater part of the shire is under forest, more than 20,000 acres of which still belong to the crown; it is called the forest of Dean, and was once deemed the principal support of the English navy. The chief rivers are the Severn, Wye, Lower and Upper Avon, Frome, Thames, Calne, Windrush, and Ledden. This county has been long famous for its butter and cheese. Large numbers of sheep are reared on the Cotswold hills and in the forest region, the latter being also noted for the excellence of its cider and perry. Coal exists in great abundance; lead, sulphuret of iron, oxide of zinc, limestone, coral, quartz crystals, celebrated as Bristol diamonds, and gypsum, are also found. The staple manufactures are woollens, cottons, silks, hosiery, hats, tick, hardware, glass, paper, and carpets. The shire is divided into 28 hundreds and 351 parishes. Capitals, Gloucester and Bristol. It returns 15 members to parliament—4 for the county, 2 each for the cities of Bristol and Gloucester and the boroughs of Cirencester, Stroud, and Tewkesbury, and 1 for Cheltenham.

GLOVE, a covering for the hand (sometimes extending up the arm), with a separate sheath for each finger, worn either as a protection to the hand, or as an ornamental article of dress. The use of gloves is traced back to very early periods. They are spoken of by Homer as worn by Laertes to protect his hands while working in the garden. Xenophon speaks of Cyrus going without his gloves. The custom of giving a glove as a pledge in concluding a contract is very ancient, and from this is supposed to have been derived the later custom of throwing down a glove as a challenge, which the opposite party accepted by picking up the glove and throwing down his own. This is traced back in England as far as the year 1245. In recent times a ceremony of the same import is performed by the parties interchanging their cards. In the middle ages gloves were an object of special regard. They were made in the most costly manner, ornamented with precious stones, and worn by kings and the church dignitaries upon ceremonial occasions. It was her glove which the lady of chivalric times gave her faithful knight to wear in his helmet as a pledge of her favor; and the same token was presented by the highest officials in conferring dignities and bestowing lands. Down to the present time curious ceremonies have been associated with gloves, as the custom in some parts of Europe of taking them off when entering the stable of a prince or great man; or else forfeiting them or their value to the servants. In hunting, the same ceremony must be performed under the same penalty at the death of the stag. Glove money is a term of ancient use, meaning money given to servants to buy gloves. Presenting a

pair of gloves for any favor rendered is a very old custom, which in the United States is retained among the Episcopalians and other religious sects, who at funerals make it a point to furnish the attending clergy and bearers with pairs of black gloves and scarfs. This had proceeded to such an extravagant extent in Massachusetts that the legislature forbade the practice under the penalty of £20.—Gloves are made of a variety of materials, according to the use they are designed to serve. In cold regions they are of the warmest wool, or of the skins of animals with the fur upon the outside. Thick buckskin, often lined with soft woolen, is also used, but in more moderate climates lighter qualities of leather, to the softest kid, are employed, and also worsted, cotton, and silk. The preparations of caoutchouc are applied to the same purpose. The art of glove making is carried to its highest perfection in the manufacture of kid gloves by the French. The English, who make excellent gloves of heavier varieties of leather, themselves admit their inability to attain the skill of the French in this department, and largely import the best Parisian gloves. The difference is exhibited even in the cutting of the skins to the best advantage; a process performed with a pair of scissors after stretching and rubbing the skin upon a marble slab with a blunt knife. A skin is first cut longitudinally through the middle, by which it is divided into two equal and similar parts, and the single strip for the palm and back is next cut off from one end of the half skin. The pieces for the thumb, the gussets for the fingers, and other small pieces to be inserted, must all be worked out either from the same skin or from others precisely similar. In this work, it is said, "a Frenchman will generally manage to get one or two pairs of gloves more than an Englishman can from the same skins, and these not inferior, or scanty, but as well and handsomely shaped as the rest. This clever and adroit manipulation of the leather is an object of great importance in France, where not less than 875,000 dozens of skins of all kinds are cut up into gloves every year." The nearly square piece cut off is folded over upon itself, giving a little more width for the side designed for the back of the hand; and upon this oblong double strip, the workman, measuring with his eye and finger, marks out the length for the clefts between the fingers, which he proceeds to cut and shape. Making the hole for the thumb is a matter requiring the greatest skill, for a very slight deviation from the exact shape would cause a bad fit when the parts are sewed together, resulting in unequal strain and speedy fracture when the glove is worn. By late improvements, introduced by M. Jouvin, the thumb piece, like the fingers, is of the same piece with the rest of the glove, requiring no seam for its attachment. The cutting also is performed in great part by punches of appropriate patterns, and some of these are provided with a toothed apparatus somewhat resembling a comb, which pricks the points for

the stitches. The seams are sewed with perfect regularity by placing the edges to be united in the jaws of a vice, which terminates in fine brass teeth like those of a comb, but only $\frac{1}{4}$ of an inch long. Between these the needle is passed in successive stitches. When the sewing is completed the gloves are stretched, then placed in linen cloth, slightly damp, and beaten, by which they are rendered softer and more flexible. The last operation is pressing.—The chief branch of the manufacture carried on in the United States is that of buckskin gloves, a kind of glove more peculiarly American than any other; and the most important seat of this business is at Gloversville, Fulton co., N. Y.

GLOVER, RICHARD, an English poet and politician, born in London in 1712, died in 1785. He was educated for a mercantile life, but early manifested a love of letters, and at the age of 16 wrote a poem to the memory of Newton. In 1787 he published an epic on the Persian invasion of Greece, entitled "Leonidas," which was thought to have an application to English politics, and was for a time much admired. A continuation to it, under the title of the "Atheniad," appeared in 1787. His "London, or the Progress of Commerce," and a ballad called "Hosier's Ghost" (1789), were written to rouse his countrymen to a war with Spain. He was active in politics as an opponent of Walpole, and was returned to parliament for Weymouth in 1760. He wrote several tragedies, and a diary which was published in 1818, and in the following year an "Inquiry" appeared attempting to prove that he was the author of the letters of Junius.

GLOW-WORM, a name given to the female of several sericicorn beetles, of the genus *lampyrus* (Fab.). The antennæ are short, with cylindrical and compressed articulations; the head is concealed beneath the anterior margin of the thorax; the eyes and the mouth are small; the body is rather soft and depressed, with the sides of the abdomen serrated; the elytra are coriaceous and slightly flexible. The females are wingless, with rudiments of elytra at the base of the abdomen, and their general appearance to the uneducated eye is that of a worm, explaining fully the popular name of glow-worm in England and *ver luisant* in France. In the old Linnæan genus *lampyrus* there were as many as 60 species, which have been distributed into different genera, so that there were only 9 species left in the genus in the last edition of Dejean's catalogue. There are 4 well known species of glow-worm in Europe, *L. noctiluca*, *Italica*, *splendidula*, and *hemiptera*; the second is probably the species whose luminous faculty was known to the ancients, the *λαμπροψης* of the Greeks and *cicindela* of the Romans. Both sexes are luminous, though the light is strongest in the female; the light does not come from the thorax as in the fire-fly (*steler*), but from the posterior part of the abdomen on its upper and under surfaces. The English glow-worm (*L. noctiluca*, Linn.) is the largest European spe-

cies, about $\frac{3}{4}$ of an inch long in the male, and the female about an inch; the male is brownish gray, with a reddish gray margin on the superior portion of the thorax, and has both wings and elytra; the female is wingless, of a uniform yellow white, with a very thin skin below; in both sexes the luminous spots show themselves as 4 bright points, 2 on the antepenultimate abdominal segment and 2 on the next posterior. The *L. Italica* is next in size, and is found in southern Europe, as the first is in the northern countries; the color is black, with red prothorax and legs; both sexes are winged, and much resemble each other, the apterous females spoken of by some entomologists being the larvæ. The *L. splendidula* is common in Germany; the male is winged, of a brown gray color with a bright glassy spot on the convex margin of the prothorax; the female, of a whitish yellow color with a brown spot on the centre of the prothorax, has no wings and very short oval elytra; the luminous spots are 2 transverse bands on the lower surface of the 2 penultimate abdominal segments, and in the female the whole abdomen diffuses a weak light. *L. hemiptera*, a southern species and the smallest, $\frac{1}{4}$ of an inch long, is of an opaque black color, lighter in the female, the posterior ventral plates being whitish; the males have truncated elytra, the females none; the light is diffused from 2 round spots on the penultimate segment; the larvæ are probably luminous, as those of the preceding species were found to be by Burmeister. The first 3 species conceal themselves in the daytime and appear at night, the males flying about in the warm summer evenings, while the females betray their situations by their tranquil light among the shrubs; the last species creeps also by day, especially in damp weather, appearing toward the end of April; the 3d species occurs about the end of May and the beginning of June, while the 1st is found most abundantly toward the end of summer. The light is greenish or more commonly bluish white, intermittent or continuous at the will of the insect, extinguished in time of danger, and increased by active motion, sexual excitement, or artificial heat; it may continue some hours after death, and when lost may be reproduced by warm water; poisonous gases destroy the light with life, while oxygen increases its brilliancy; electricity produces no effect on the light, while galvanism increases or reproduces it in dead insects. The researches of Kolliker and others show that at the shining spots is found a whitish, transparent, fatty mass, permeated by very numerous tracheæ; this mass will shine when removed from the body, and in warm water for a long time, and its particles rubbed upon the fingers display a light resembling that from phosphorized mixtures. This insect, from the beauty of its light, has always excited the wonder and admiration of mankind, and has been the subject of many exaggerated stories and not a few exquisite poems, and in the minds of the country residents in England

is associated with the most pleasing recollections of calm summer evenings and lovers' walks in the springtime of life. The eggs of the glow-worm, the larva, and the nymphs, are luminous; the eggs are hatched after a few weeks, and the larva resemble the perfect females, having a body of 12 segments, the first 3 of which bear each a pair of feet; the head is small, and, like the caudal segments, retractile; they thrive well in captivity when kept in moist earth or herbage, and supplied with slugs and snails, which they kill with their arched and sharp-pointed jaws, and eagerly devour; about a week is occupied in assuming the state of nymph, and in about 8 days longer they appear as perfect insects. The nymph is larger than the larva, but not quite so long; the color is at first pale yellow, with two reddish spots on the posterior part of the thorax and the segments, but the dull color of the perfect insect is visible toward the end of the nymph state; the larval jaws disappear, and the antennæ are seen to have 11 joints, and the tarsi 5; the last abdominal rings are very brilliant, and indeed the whole body seems phosphorescent. According to Dufour, the alimentary canal of the perfect female is twice as long as the body, and the cesophagus exceedingly short, immediately dilating into a short crop. The substance from which the luminous property is derived has been often made the subject of experiment, but as yet, according to Matteucci, without the detection of any phosphorus in it, though the circumstances attending the light resemble the conditions under which this substance is luminous, being increased by warmth, diminished by cold, and destroyed by irrespirable gases, oil, alcohol, acids, and strong saline solutions; these phenomena admit of a better explanation on Matteucci's theory. This author, in his *Leçons sur les phénomènes physiques des corps vivants*, explains all cases of animal phosphorescence on physico-chemical principles, regarding this as one of those singular mysteries of nature, seemingly introduced among the phenomena of life to lead man to consider and admire the power of the Creator. From his experiments we know that the light of the glow-worm may cease before the death of the animal, or may be considerably prolonged after this event; that the light is without heat, as far as our rude instruments can detect; that it ceases soonest in carbonic acid, and in hydrogen in from 20 to 40 minutes; that it is increased in oxygen, and lasts 8 times as long as in other gases, both for parts and for the entire insect; that it consumes a portion of oxygen, which is replaced by carbonic acid, and is therefore the product of a true combustion; that when not shining, and in contact with oxygen, none of this gas is taken up, and no carbonic acid is formed; that heat to a certain extent increases, while cold diminishes its brightness; that when the luminous substance has been altered by too great heat or the action of gases so as to lose its phosphorescence, this property cannot be reestablished; finally, that carbon, and not phos-

phorus, is one of the elements of this substance, and that the phosphorescence is produced by the combination of the carbon with oxygen. The luminous matter from the living insect, according to the same author, has a peculiar odor resembling that of the perspiration of the feet; it is neither acid nor alkaline, dries rapidly in the air, seems to coagulate in contact with dilute acids, is not sensibly soluble in alcohol, ether, or weak alkaline solutions, but is dissolved in concentrated sulphuric and hydrochloric acids with the aid of heat; chemical tests exclude the idea of the presence of albumen, and the ordinary ammoniacal products are disengaged by heat. The oxygen of the atmosphere introduced by the numerous tracheæ comes in contact with this substance, *sui generis*, composed principally of carbon, hydrogen, oxygen, and nitrogen. There are other instances of combustion of organic substances in contact with the air, which absorb oxygen and give out carbonic acid—as, for instance, wood and fish in process of decay, greased cotton, and charcoal in a minute state of subdivision—in none of which phosphorus is present; the heat disengaged is so small and escapes so readily, that there is not sufficient accumulation in most of these cases to be indicated by our thermometers. The phosphorescence of the sea is owing to minute organisms, which become luminous under certain physico-chemical conditions not satisfactorily determined; the annals of medicine furnished well attested cases of the appearance of flame arising from the bodies of the sick, before the days of mesmerism, and of phosphorescent transpiration of the feet, which are interesting in connection with the above mentioned odor in the glow-worm; these, and other similar facts, are at present not at all explained. According to some botanists, the heat developed during the flowering of plants is sometimes accompanied by phosphorescence. The intermittence of the glow-worm's light, and its sudden changes from darkness to brightness, as far as present investigations go, are dependent on the different amounts of air introduced into the tracheæ, and the varying activity of respiration and muscular action. The change in the food of the glow-worm, from animal juices in the larva state to tender plants in the perfect condition, explains the contradictory statements of authors as to the habits of this insect; and the failure of the attempts to introduce it as an ornament to shrubberies and lawns has generally arisen from ignorance of the fact that the larva cannot be raised on vegetable food alone; beside moist herbage or damp earth, minute land shells must be supplied.—Phosphorescence has been noticed in annelids and star-fishes (*ophiura*); this property has been explained by Quatrefages as depending on the irritability of the muscular fibres. A few specimens of an articulated animal which may be called a glow-worm have been of late years found in the summer season in various parts of southern New England. The following descrip-

tion will give an idea of the creature: the head is small and flat, with very short antennæ; the color is cream-white, the length about 14 lines, and the whole of this is lighted up at night with a permanent luminousness less than that of the elaters of the West Indies; the light begins to show itself between the segments, of which there are 12, and at the stigmata, from which it spreads until the whole animal is illuminated, seeming a stick of light without joints or stigmata; most brilliant soon after midnight, they gradually fade to the ordinary whitish color at daybreak.—In all these cases of phosphorescent articulates, it is difficult to say what is the precise purpose of the light, whether to illuminate their path, to enable their companions to find them, or to inspire fear in their numerous enemies. (See FIRE-FLY.)

GLUCINA (Gr. γλυκύς, sweet), an earth, first obtained by Vauquelin in 1798, consisting, according to Berzelius, of 2 atoms of the metal glucinum, united with 8 atoms of oxygen; but Awdew and others regard it as a protoxide, GIO. It is found only in a few minerals, as the emerald, beryl, euclase, &c., being contained in the first two in the proportion of 18½ per cent., combined with silicic acid. It is obtained in the form of a white powder, of specific gravity about 3, closely resembling alumina. It is distinguished by its solubility, when freshly prepared, in a cold solution of carbonate of ammonia, and by its tendency to form a carbonate by exposure to the air; also by not giving a blue color in the blowpipe test with nitrate of cobalt. The properties of glucinum, the metallic base of glucina, have been recently investigated by Debray (*Annales de chimie physique* [8], xliv. 5), who obtained it from the chloride by reduction with sodium, the original source being the emerald of Limoges. Its properties differ from those before given by Wöhler, who obtained it in a platinum crucible. He found it a white malleable metal, that could be rolled in sheets like gold, of density 2.1, its melting point below that of silver. It cannot be made to burn in pure oxygen, but appears in the trial to be slightly oxidized on the surface, by which it is protected from further change. It resists the action of sulphur, but combines with chlorine and iodine. Its alloy with silicium is a hard brittle substance, susceptible of a high polish. Glucinum is soluble in sulphuric and in hydrochloric acids, hydrogen being evolved. Nitric acid acts upon it only when heated, and then slowly. It dissolves in caustic potash. Its symbol is G; chemical equivalent, 4.7.

GLUCK, CHRISTOPH WILBALD von, the regenerator of the modern musical opera, known in literature as the Chevalier or Ritter von Gluck, was the eldest son of Alexander and Anna Walburga Gluck, born at Weidenwang in the upper Palatinate, not many miles from the Bohemian boundary, July 2, 1714, died in Vienna, Nov. 15, 1787. It is proper to state here that the dates and other particulars in this article, which the reader may note as different from those

usually given in biographical notices of Gluck, are drawn from documentary evidence substantiated or first given to the public by Anton Schmid, of the imperial library at Vienna, in 1854 (*Glucks Leben und tonkünstlerische Wirken*). Alexander Johannes Klukh, the father (as he always wrote his name), began life as huntsman of Prince Eugene of Savoy, afterward removing to Weidenwang as forester, where his son, the future composer, was born. In 1717 he entered the service of Count Kannitz in North Bohemia, in 1722 was appointed chief forester by Count Kinsky, in 1724 entered the service of Prince Lobkowitz at Eisenberg, and closed his career in 1747 at Reichstadt in the service of the grand duchess of Tuscany. Thus the young Christoph came into Bohemia at the age of 8 years, to the land which, owing to its great number of wealthy nobles and convents, was in the early part of the last century the most favorable to the development of musical talent. At that period, in the gymnasia and the Jesuit colleges, music was earnestly cultivated, and every nobleman had his musical chapel; all churches of any pretensions, very many of the smaller parish churches even, had their choirs, supported by ample funds. The treatment of Gluck and his brothers by the father was hard even to tyranny; the composer in his old age well remembered being forced with his brother Anton to follow his father in the coldest winter weather into the forests, sometimes barefoot "to make them tough." The children had the best school instruction in Kamnitz and Eisenberg, and from his 12th to his 18th year Christoph was sent to the gymnasium at Kommatou. The boy carried with him a good degree of knowledge both in singing and playing bowed instruments, and in the school of the Jesuits his musical talents were specially cultivated. He became a chorister in the principal church of the place, and gained some knowledge of the harpsichord and organ. At 18 years of age he finished his gymnasial course, and went to Prague to enter the university. His studies were not long continued there, for with the increase of his father's family the pecuniary aid from home became less and less, until the student was at length obliged to devote himself to music for his subsistence. He gave lessons in singing and upon the violoncello, sang and played in several of the principal churches for a small monthly salary, and during vacations sang and played in the villages of the surrounding country, sometimes being paid in one with eggs, which in another he exchanged for bread. So in time he gained skill and confidence to appear in larger towns as a virtuoso upon the violoncello, no more dreaming of the great future before him than Haydn did when playing with the street orchestra of Vienna 16 or 18 years later. By degrees the youth attracted the attention of the Bohemian nobles, and the family of Prince Lobkowitz became in an especial manner his protectors. When therefore in 1736 his love of music and desire for better opportunity of

study carried him to Vienna, the house of the prince was opened to him, and a salary was given which enabled him at length, at the age of 22, to enter upon the study of the fundamental principles of musical science. He now had opportunity also to hear the works of Fux, Caldara, the brothers Conti, Porcile, and other great dramatic and church composers, adequately performed—works which filled him with astonishment and delight, and aroused an ambition some time to be able to equal them. The Lombard prince di Melzi, hearing Gluck both as a singer and violinist, in the soirées of Lobkowitz, was so pleased with him as to appoint him chamber musician, take him to Milan, and place him under Sammartini, at that time a famous director, organist, and composer. This life of laborious study and musical practice in the house of the prince continued 4 years, during which the young German had given so many proofs of his talent in composition, that in 1740 he received an order to compose an opera for the court theatre of Milan. Feeling himself now equal to the work, he gladly accepted it. The old field of the Italian opera of Handel's time had now been nearly exhausted, and the works of the day, even those of the greatest masters, had gone down in the scale until they were little more than pieces of music written to give the singers opportunities to exhibit their powers. Real musical expression was one of the last things which entered into the thoughts of the composer. Hence the first work of Gluck, though not that in which he really opened a new era for the lyric stage, has an importance in musical history beyond any other of that time, unless the oratorios of Handel be excepted. The text chosen for him was the *Artaserse* of Metastasio, a libretto which in its form was sufficient—in case Gluck had then, which he had not, thought out the system which he afterward adopted and which produced an entire revolution in the musical drama—to have prevented him from striking out an entirely new path. Still the composer had an indistinct feeling of the hollowness and insufficiency of the then recognized forms of dramatic composition, and ventured to depart from them so far as possible, and make expression the great object of his music. He completed the work, with the exception of one air, in his own manner, and in 1741 had it in study. At the first rehearsal in the theatre a large company was present, full of curiosity and burning impatience to hear the new work. It proved so different from what they were accustomed to hear as to be generally received with smiles, and shrugs, and jokes upon the German composer. Gluck let all pass without remark. For the final rehearsal he composed the wanting air in the strictest style of the day. It was a beautiful piece for the singer, and when the audience heard it, they broke into the loudest applause, and with one consent attributed it to Sammartini. Gluck remained silent. The first public performance came off with appropriate scenery and action.

The house was crowded. The interest arose with every number, the music meeting with the most decided success, until the modish air, which proved so "stale, flat, and unprofitable," so out of character with all the rest, that Gluck had to withdraw it and substitute one more in the spirit of his work. The success was triumphant, and the composer was called from city to city of Italy to direct the *Artaserse*. He was now the great operatic composer of that era. In 1742 he wrote *Demofonte*, text by Metastasio, for Milan; *Demetrio* and *Ipermestra*, texts by the same, for Venice; in 1743, *Artamene* for Cremona, and *Siface* for Milan; in 1744, *Fedra* for Milan; in 1745, *Alessandro nell'Indie*, by Metastasio, under the title *Poro*, for Turin. His fame had now extended through Europe, and Lord Middlesex invited him to London to compose for the theatre in the Haymarket. In 1745 Gluck set out in company with Prince Lobkowitz for the English capital, but upon his arrival found the theatre closed. On Jan. 7, 1746, however, it was again opened, and with *La caduta de' giganti*, written in honor of, and performed before, the duke of Cumberland, music by Gluck. Burney describes this performance, and explains the ill success of the music as owing wholly to its inadequate representation. Even under this load it lived through 5 representations. The often quoted remark of Handel, that Gluck knew as much of counterpoint as his cook, deserves a word of notice. Gluck was not of the Saxon school, of which Handel and Bach are the two great names; nor does one go now even to his greatest works for distinguished examples in the contrapuntal style of composition. His excellences are of another order. The work of a still young man may have very naturally appeared feeble to Handel, who then looked upon music with the judgment of a man of 60 years. Handel's good will to Gluck is proved by an anecdote which Reichardt heard in London. Gluck, dissatisfied with the ill success of *La caduta de' giganti*, complained to Handel, and showed him the score. Handel said: "You have taken too much pains with your opera, that's all; that should not be done here; for Englishmen, you must think of something striking—something that hits right upon the drum head." This is said to have led Gluck to add trombones to the choruses, and with good results. The *Artamene* was afterward given very successfully. This journey to England was in fact the turning point in Gluck's life, although the fruits of his study and observation did not appear in full for many years. On his way to London he had remained some time in Paris, and there had opportunity to study the tragic declamation and extraordinary truth of expression in the works of Rameau, which wrought powerfully upon his imagination, and strengthened his own half-developed theory of operatic composition. In London the majestic character of both melody and harmony in Handel's oratorios, and the simple but natural dramatic style of Dr. Arne, made an equally deep impression. To all this

must be added the effective and dramatic use of chorus and ballad in the opera of Rameau. Here were so many means of the highest dramatic effects, each new, each worthy of being made his own, but not alone. The problem arose in his mind how to join them all in one magnificent whole. Before he left London he had a notable proof that the principle which lay at the groundwork of his first opera—that of composing music with regard alone to the expression of the passion and situation of the moment upon the stage—was a correct one. In addition to the two operas above named, he had been commissioned by the London managers to prepare a *pasticcio*, *Piramo e Tisbe*, that is, to adapt from other operas music to this new text. In doing this, he selected from his works none but the pieces which had been most highly applauded, and had become favorites with his audiences. These he adapted with all the skill and science of which he was master; but to his surprise, astonishment even, he found that with a new text, new action, and new situations, the music seemed to have lost all its power. He concluded from this that all really successful operatic music, having a higher aim than merely to please the ear, is necessarily of a character which unfits it for any other text and situation than that to which it owes its origin. Having thus arrived at a fundamental principle of dramatic composition, he took this as a starting point, and gradually wrought out a system, upon which, at a future period, he was to base the success of a series of imperishable operatic works. The leading points of this system are: 1, that dramatic music can only reach its highest power and beauty when joined to a text simple, truly poetic, and exhibiting natural and definite emotions and passions with the highest possible truth to nature; 2, that music might be made the language of emotion, capable of expressing the various feelings of the heart; 3, that the music must follow with all possible exactness the rhythm and melody of the words; 4, that in accompaniments, the instruments must be used to strengthen the expression of the vocal parts by their peculiar characters, or to heighten the general dramatic effect, by employing them in contrast to the voice, as the text or dramatic situation might demand. From these principles it followed that the beautiful arias, which then were held to be the highest efforts of the musical art, though in fact unsurpassable as means of sensual gratification to the ear, so perfect were many of them in form and delicious melody, could never deeply touch the soul nor rouse any lasting emotion. In his later years Gluck was in the habit of saying, when an air of this kind was commended: "Yes, it is right beautiful; but it does not draw blood." The composer left London toward the close of 1746, and returned to Germany. Dlahacz says he became a member of the electoral orchestra of Dresden with a respectable salary, which seems probable, but in fact none of the biographers

have cleared up the chronology of his life for the 2 or 3 years after his return. On June 29, 1747, an opera in one act, *Le nozze d'Ercole e d'Eda*, music by Gluck, was performed at Pilnitz, a few miles above Dresden, in honor of the marriage of Princess Anna, daughter of Augustus III. According to Schmid, *La Sémiramide riconosciuta*, text by Metastasio, music by Gluck, was performed at Vienna on Maria Theresa's birthday, May 14, 1748; and in the autumn of the same year a newspaper contains a paragraph of news from Hamburg, which is dated Oct. 8, and says: "Herr Gluck, so well known in music, is at present capellmeister here in place of Scalabrini." In 1749 he was called to Bohemia by the death of his father, and after settling the small estate left by him, went once more to Vienna, which city he made henceforth his home, only leaving it when called to Italy and Paris to produce his works. In the Austrian capital he soon became a welcome guest in all the musical circles, not more from his great excellence as a singer and a virtuoso upon the violin or violoncello, and from his fame as a composer, than from his great social talents. In the house of Joseph Pergin, a banker and wholesale merchant, he was received both as a friend and as music teacher of the two daughters. With Marianne he fell in love, and his passion was returned. The mother approved the match, but when the young man applied to the father for the hand of his daughter, he was rudely refused, as being but a musician, and with no prospect of being able to support the young lady in a style fitted to her rank and position. Surprised and deeply wounded, Gluck gladly accepted an order to compose *Telemaco* for the theatre Argentina at Rome, and left Vienna at once, in such haste to be away, that, without waiting for his passport, he smuggled himself across the boundary in the habit of a Capuchin monk. In 1750 news came to him that Pergin was dead. As soon as his opera was upon the stage, where it, like all his other works, was successful, he hastened back to Vienna, and on Sept. 15 celebrated his marriage with Marianne. The marriage proved childless, but few have been happier, and seldom even during his longest and most tedious journeys were Gluck and his wife separated. In 1751 he visited Naples, to produce his *Clemenza di Tito*; in 1754 he composed *Le Cinesi*, a fantastic production, performed at Schloßhof before the emperor and Maria Theresa; and the same year he was appointed chapelmaster of the imperial opera at Vienna, which office he held until 1764. Before the close of the year he was again called to Rome, and produced there *Il trionfo di Camillo* and *Antigono*, which gained him from the pope the order of knight of the golden spur. Hence his title in musical history, Chevalier or Ritter. In 1755 he produced the music to Metastasio's *La danza*; in 1756, *L'innocenza giustificata* in one act, and *Il re pastore* in three. Between

1755 and 1762 he composed also a great number of airs and other pieces for a series of 10 French operettas and vaudevilles performed in Vienna, at the same time laboring heroically to make up for the deficiencies of his early education. In 1760 his principal work was *Teside*, a serenata composed for the nuptials of the archduke Joseph; and in 1761 a most successful ballet, *Don Juan*, or *Das steinerne Gastmahl*, founded upon the same fable afterward employed by Da Ponte in his text to Mozart's immortal opera. In 1762, *Il trionfo di Clelia* was composed at Bologna, met with the invariable success of Gluck's productions, and then its author returned to Vienna to enter upon his new path. However satisfied the public was with his music, he was not so. He felt himself continually cramped by the character of Metastasio's libretti, which were rather lyric dramatic poems—though of the highest excellence in their kind—than true dramas. Two years before his journey to Bologna, Gluck had opened his mind upon this subject to Raniero Calzabigi, a councillor in the department of finance, and discussed it with him in all its length and breadth. Calzabigi, himself a poet, had long felt the defects of which Gluck complained, was rejoiced to find the views of so eminent a composer correspond so perfectly with his own, and promised to prepare a text which should enable the musician to bring their common views to the public test. Upon his return from Italy Gluck found ready for him the libretto of *Orfeo ed Euridice*. The poem differed so completely in construction from the Metastasian type, which then alone was recognized as classic throughout Europe, that Calzabigi was not without anxiety lest this fact should prove sufficient to insure its condemnation. A word against it from the old dramatic autocrat would suffice for this. He accordingly called upon Metastasio, and requested him not to declare himself openly against the new style adopted. The poet confessed himself dissatisfied with it, but consented to hold his peace—"the work would speak for itself." It would not be easy to find in musical history another case in which a new style of dramatic lyric composition, new ideas and principles, have been subjected to so severe a test as in this. Orpheus, Eurydice, and, in two or three short scenes, Amor, are the only characters represented. At the beginning and end a chorus of Greeks, in Tartarus a chorus of shades and demons, in Elysium a chorus of blest spirits, each occupying a single scene, with choral music and ballet, is all that divides the attention from the three leading characters. The subject, opening with a chorus at the tomb, lamenting the death of Eurydice, is the familiar myth, only changed at the close, where Amor appears and finally restores the beloved one to Orpheus. There is but little action, and that of the simplest character. Every thing depended upon exciting the sympathies of the audience at the outset, and holding them to the end, and this too by

musical means as new and strange then as those of the old Handelian opera would appear to us. Twice in this work Gluck has shown the daring of genius trusting to its own powers, in a manner not surpassed by Beethoven himself. At the close of the first chorus Orpheus dismisses his friends, and is left alone not merely to execute a recitative and single air, written expressly for the singer to exhibit his powers, but a series of them, in which not an ornament or cadenza is admitted, and which nothing but the depths of expression in Gluck's music could redeem even now from the fatal fault of tedium. The other case is that in which Orpheus entering Tartarus is confronted by demons and shades, who by the force of his music at length are led to give way and allow him to pass on to Elysium. The problem for Gluck to solve was so to write that the auditor might feel the means equal to the end. A failure here would have exposed the composer to a ridicule which would have condemned his work, and his theory too perhaps, for ever. On Oct. 5, 1762, the opera was performed in public. Surprise and astonishment were the emotions with which the audience left the house. All hearts had been strangely moved. It had interested the company from the first singer to the most insignificant dancer in the ballet, and was given with rare perfection, and, strangely enough, just as Gluck desired—no cabala, no rebellion against his authority. The novelty of the style was soon forgotten. The music made its way to all hearts, it became a most popular work in Vienna, and now, at the close of a century since its production, is still a stock piece in Berlin, having lost no particle of its freshness and pathos. In the next 8 years, 1763, '4, '5, Gluck composed *Ensis*, text by Metastasio; *La rencontre imprévue*, text by L. H. Dancovot (afterward very popular in a German translation with the title *Die Pilgrime von Mekka*); *Il Parnasso confuso*, a dramatic poem by Metastasio, performed in the palace at Schönbrunn by the 4 daughters of Maria Theresa, sisters of Maria Antoinette, their brother, the future emperor Joseph, playing the harpsichord; revised *Telemacco* for the Vienna stage, and composed *La corona* for the archduchesses. The last piece was never performed, owing to the sudden death of the emperor Francis. None of these works, although they gave Gluck opportunity to prove his inexhaustible fund of melodic and harmonic beauty, were such in dramatic form as enabled him to follow the path struck out in the *Orfeo*. In the mean time Calzabigi had prepared another text for him, founded upon the *Alceste* of Euripides. Admetus, king of Phera, is attacked by a mortal illness. Apollo obtains from the Fates a promise of his recovery if any one can be found to die in his stead. Alceste, the queen, offers to die for him, parts from her husband and children, but is at length saved by Hercules, and restored to them. On this slight framework the poet succeeded in building a drama full of feeling, and one which offered a great

variety of scenes and passions for the inspiration of the composer. The promise of the *Orfeo* was more than fulfilled. But it was not until after several performances that the public learned to understand and appreciate it. Then indeed admiration rose to the point of enthusiasm. In 1769 the *Alceste* was printed in score, with the celebrated dedicatory epistle to the grand duke of Tuscany, in which the composer ventured, after so successfully applying the test of experiment, to announce to the world the new principles of dramatic musical composition, which he had now reduced to a system. "When I undertook to set the opera *Alceste* to music," he writes, "I purposed carefully to avoid all those abuses which the mistaken vanity of the singers, and the too great good nature of composers, had introduced into the Italian opera; abuses which reduced one of the noblest and most beautiful forms of the drama to the most tedious and ridiculous. I sought therefore to bring back music to its true sphere, that is, to add to the force of the poetry, to strengthen the expression of the emotions and the interest of the situations, without interrupting the action or deforming the music by useless ornamentation. I was of opinion that the music must be to the poetry what liveliness of color and a happy mixture of light and shade are for a faultless and well-arranged drawing, which serve only to add life to the figures without injuring the outlines. I have therefore taken care not to interrupt the actor in the fire of his dialogue, and compel him to wait for the performance of some long tedious ritornello, or in the midst of a phrase suddenly hold him fast at some favorable vowel sound, that he may have opportunity by some long passage to exhibit his voice, or make him wait while the orchestra gives him time to get breath for some long *fermate*. Nor have I thought myself at liberty to hurry over the second part of an aria, when perhaps this is just the most passionate and important part of the text, and this only to allow the customary repetition of the words four times; and just as little have I allowed myself to bring the aria to an end where there was no pause in the sense, just to gain an opportunity for the singer to show his skill in varying a passage. Enough; I wished to banish all those abuses against which sound common sense and true taste have so long contended in vain. I am of opinion that the overture should prepare the auditors for the character of the action which is to be presented, and hint at the progress of the same; that the instruments must be ever employed in proportion only to the degree of interest and passion; and the composer should avoid too marked a disparity in the dialogue between air and recitative, in order not to break the sense of a period, or interrupt in a wrong place the energy of the action. Further, I considered myself bound to devote a great share of my pains to the attainment of a noble simplicity; therefore I also avoided an ostentatious heaping up of difficulties at the expense of

clearness; I have not valued in the least a new thought if it was not awakened by the situation and did not give the proper expression. Finally, I have even felt compelled to sacrifice rules to the improvement of the effect." In 1769 Gluck produced a 8d opera in the new style, *Paride ed Elena*, text by Calzabigi. Since 1764 he had been free from the cares and duties of chapel-master, and was able to devote all his energies and studies to his operas. The result, as we have stated, was, in the case of the *Alceste*, all that he could wish at home, in Vienna; in the new opera, although the music is equally masterly, the subject was unfortunate, and, as a drama, not of particular interest to the public. It became popular, therefore, only with musicians, and has in late years never been revived. The next year he published it in score, and in dedicatory epistles addressed to the duke of Braganza defended himself and his system against the attacks of the north German critics, whom he charged with pretending to judge of music written with a single eye to effect upon a grand stage, with every accessory studied to perfection, after hearing it inadequately performed, without due rehearsals and with imperfect properties and machinery, or what was still worse, after running the score through in a chamber at the pianoforte. Soon after producing the *Paride ed Elena* (1769), Gluck was called to Parma to compose festival music upon occasion of the marriage of the grand duke to Maria Amalia, daughter of Maria Theresa. Instead of a long opera, divided into acts, 4 short one-act pieces were prepared, *Le feste di Apollo*, *L'atto di Bauli e Filemone*, *L'atto d'Aristeo*, and for the 4th the *Orfeo* given in 7 scenes. The first 3, in the Italian style, were undertaken by the singers with delight, and awaited by the public with the brightest anticipations; but people shook their heads at the idea of a piece which in its construction ignored the principles of Metastasio, however much it might have delighted a German audience, being served up before the Italian public. Millico, the contralto, when the part of Orpheus was brought to him to study, shed tears that he was compelled to undertake a part which, as he thought, could do him no honor. Studying it, however, with Gluck himself, he soon felt its power. It became a masterpiece of singing and action in his hands, and his love and admiration for the composer became so strong that he afterward followed him to Vienna. The public, too, became so captivated with it that they utterly refused to hear the *Armida* of Fraetta, which the directors of the theatre some time afterward announced in place of the *Orfeo*. Gluck returned to Vienna, and remained there now several years, one of the marked men of the capital, one of the ornaments of the best society, whose house no stranger of distinction failed to visit. During this time he composed nothing for the stage, though his pen was not idle. He set many songs and odes of Klopstock, and some scenes of his

Hermannsschlacht, to music. But his mind was still dwelling upon the reform of the opera. Successful as his 3 operas in the new style had proved, he was not himself satisfied that he had succeeded in putting his system to such a test that it could admit of no further dispute. There existed at that epoch, so at least Gluck believed, but one stage in Europe, which, from the superiority of its singers, both as vocalists and actors, from the splendor of its decorations and the perfection of its machinery, the number of its chorists and dancers, and the great size and fine execution of its orchestra, offered to the composer all that he could in reason demand. This was the royal opera at Paris, and the idea of composing a tragic opera on the grandest scale for its boards, upon which he might lavish all the resources of his genius and the studies and experience of a life, now of nearly 60 years, was one which gained continually a more complete possession of his thoughts. At this time a French gentleman of genius and a highly cultivated taste, Bailly du Rollet, whom Gluck had known long before in Rome, was in Vienna, an attaché of the French legation in that city. With all his prejudices in favor of French music, which then formed a much more distinct school than in our days, Du Rollet was wonderfully impressed by the ideas of Gluck, and by the 8 operas in which those ideas had been exemplified. The magnificent *Iphigénie en Aulide* of Racine seemed to Gluck to offer a subject worthy of his highest efforts, and this Du Rollet undertook to reduce to a suitable form for musical composition. His task was completed to the satisfaction of the composer, who now laid aside everything else, devoting himself exclusively to the study of his text. He first perfected his plan from beginning to end, so that by no possibility could there be any want of due proportion in the parts. Not until this labor was fully perfected did he begin upon the music. In the style which he adopted he followed Rameau and the other best French models just so far as this was possible without invading the principles of dramatic composition, as explained by himself in his dedicatory epistles. When Dr. Burney visited Vienna in 1772, the *Iphigénie* was finished, but only a few of the finest scenes were committed to paper; the rest was retained in the memory of the composer. These scenes, however, had been performed in presence of the court, and had fully met the highest anticipations. On Aug. 1, 1772, Du Rollet wrote to D'Auvergne, a director of the Paris opera, giving an account of Gluck and his system, and a description of the new opera *Iphigénie en Aulide*. Instead of answering this letter, D'Auvergne printed it in the October number of the *Mercury de France*. In Feb. 1772, Gluck sent an article to the *Mercury*, in which he speaks of himself and his works with great modesty, and from which we extract a single sentence only. He would have been glad, he says, to have composed this work in Paris, because he "might perhaps have found means

there to have realized one of the cherished thoughts of his soul, i. e., to write music which should be alike expressive to all nations, and thus have done his part toward putting an end to the ridiculous difference in national music." Meanwhile D'Auvergne had written to Bailly du Rollet, and had received from him the first act of the *Iphigénie* for examination. After examining it he wrote again to Du Rollet, and made this remarkable proposition: "If the Ritter Gluck would bind himself to compose 6 such operas for the Paris academy of music, he would be the first person to interest himself in bringing them upon the stage; otherwise, not; for one such opera would be a death blow to all the previous French operas." Reichardt is authority for this statement, he having heard the fact from both parties. Unable to effect any thing with the directors of the *académie*, Gluck addressed himself to Marie Antoinette, at that time dauphiness, who had formerly been his pupil, and his petition was accompanied by strong recommendations from Maria Theresa and Joseph. Marie Antoinette conquered all obstacles, and invited Gluck to Paris with his score, promising him her protection. Late in the summer of 1773 Gluck journeyed to Paris, accompanied by his wife and his niece (adopted daughter) Marianna. To his surprise and disappointment, in no one respect did the academy of music answer to the descriptions he had heard of it, the expectations he had formed. Singing, acting, chorus, orchestra, ballet, all were worse than merely bad. Rousseau's invectives and sarcasms at a previous period were as well deserved now. Gluck had composed the opera; he had now the herculean task of forming singers, actors, and an orchestra adequate to its performance. He said afterward that, if the composer received 30 livres for his opera, he ought to have 20,000 for producing it. Gluck was a man of indomitable energy, and having the protection of the court to fall back upon, he pursued plans of making the resources of the academy equal to his demands. So autumn and two-thirds of the winter passed, and Feb. 18 was fixed upon for the first performance of *Iphigénie*. His enemies had reserved their master-stroke for this day. When it was too late to change the programme of the evening, as the cabal supposed, it was announced that the first singer was suddenly taken sick. Gluck demanded the postponement of the performance. This was refused, on the ground especially that the court had been notified, and it must go on. The composer at once applied to the highest authority, and the directors were forced to comply with his request. On April 19, 1774, the performance took place. We have no space here to detail the history of the warfare which followed between the followers of the old school of opera and the converts to the new ideas of Gluck. The contest in Vienna had been, upon the whole, a local one. Transferred to Paris, it became a contest of the whole musical world. A catalogue of the writings of the Gluckists and Piccinists on the two

sides of this question would fill one of our pages. The final result was the complete victory of Gluck. The composer followed up the *Iphigénie* with the "Orpheus and Euridyce," adapted to the French stage, with the very material alteration of changing the part of Orpheus to that of a tenor, to suit the voice of Legros, there being no contralto adequate to it. The success of the work was as striking in Paris as in Vienna and Turin. In Feb. 1775, Gluck produced *L'arbre enchanté*, in one act, at Versailles, a work of no great importance, and written merely for a festival given by Marie Antoinette to her young brother Maximilian, afterward elector of Cologne. Soon afterward the composer returned to Vienna, making the acquaintance of Klopstock, which ripened into intimate friendship, on the way to Strasbourg. In August his *Cythere assiégée* was produced at the academy, but met with no distinguished success. The subject was not one to enlist the feelings of the composer in any great degree, nor did the actors and singers have the advantage of his personal instructions. In fact, the work mainly belonged to a former period. Meantime he was zealously engaged upon 8 works, an adaptation of *Alceste* to the Prussian stage, and the operas *Roland* and *Armide*, texts by Quinault. The *Roland* he laid aside upon hearing that it had also been intrusted to Piccini, and wrote a sharp letter to Bailly du Rollet, which, without the consent of the writer, was printed in the *Année littéraire*, and seemed to embitter the other party to a high degree. Early in 1776 Gluck was again in Paris with his *Alceste*. It was produced, and hissed off the stage. The unlucky composer, who had been behind the scenes, rushed from the opera house, and meeting a friend, threw himself into his arms in tears, exclaiming: "The *Alceste* is fallen!" "Yes," said his friend, "fallen from heaven!" As this ill success was mostly owing to cabals among the singers and the personal efforts of Gluck's opponents, and as the composer had influence enough to insure its repetition, it made its way with the public, and soon took its place only below the *Iphigénie* and the *Orfeo*. The war of the wits and critics was, however, more bitter than ever. Gluck himself seems to have been not a little embittered, and his polemical writings are oftentimes excessively keen. In the midst of his ill success with the *Alceste* came the afflicting news that his niece Marianna, whose ill health had caused him this time to visit Paris alone, had been carried off with the small pox. Marianna Hedler, by adoption of the composer named Gluck, was the daughter of Gluck's youngest sister. Upon her the childless musician lavished all a father's love. She had been a pupil of Millico, and when but a child, as Burney records, was already a songstress of wonderful powers; and at the age of 16, at which she died, was probably among the very first of living singers in all the nobler qualities. Her death was the great grief of Gluck's life. It was not until Sept. 28, 1777, that the *Armide*,

text by Quinault, from Tasso, was produced. It was rather coldly received, not being at once comprehended, but gained upon the public, and took the rank it still holds, being by many held to be the greatest composition of Gluck, and by others only inferior to his later work, the *Iphigénie en Tauride*. Again crowned with success, Gluck returned to Vienna to work upon a new text, *Iphigénie en Tauride*, by a young poet named Guilbard. In Nov. 1778, he was so far advanced with it that he returned to Paris, where on May 18, 1779, it was produced. Like Haydn's "Creation," written when he was nearly 70 years of age, this opera of Gluck, written at the age of 64, ranks among the highest efforts of the composer; with many, as before stated, it ranks the first. It was the work which made the profoundest impression when produced, and which held its place the longest in Paris. It is still in a German translation one of the favorite pieces upon the Berlin stage. It was the crowning triumph of Gluck's system of operatic writing, and ended the series of works which gave direction to the genius of Mehul and Cherubini in Paris, Mozart and Beethoven in Germany, in their works for the stage. Another piece brought by Gluck to Paris at this time was the *Écho et Narcisse*, the last of his dramatic works in order of performance, perhaps also in composition. It met with no great success. He returned to Vienna, but his life as an artist may be said to have ended. In 1788 he had an attack of apoplexy, which caused him to decline the text of *Les Danaïdes*, sent him from Paris, and give it to the young Salieri, who of all the rising composers was fullest of his spirit, and who owed to him his already great success as a composer. To his dramatic compositions Gluck added only for the church a *De Profundis*, a psalm, *Domine Dominus Noster*, and a part of the sacred cantata, finished by Salieri, *Le jugement dernier*. For months before his decease, Gluck had been obliged to use the greatest precautions to prevent a return of apoplexy. Finally, one day he invited two old Parisian friends to dine with him. After the meal, coffee and spirits were placed upon the table, and Madame Gluck went out to order the carriage for the daily drive prescribed by the physician. One of the friends excusing himself from emptying his glass, the host at last seized it, swallowed its contents, and laughingly told them not to let his wife know of it, as every thing of the kind was forbidden to him. The coach being ready, Madame Gluck invited the guests to amuse themselves in the garden for a short time. Gluck took leave of them at the coach door. It was his last adieu. Fifteen minutes afterward he had another stroke; the coachman hurried home; his master had already lost all consciousness, and a few hours later breathed his last.

GLÜCKSTADT, a town of Denmark, in the duchy of Holstein, on the right bank of the Elbe, 27 m. N. W. of Altona, the seat of various provincial courts; pop. 6,200. The inhab-

itants are chiefly engaged in commerce and the whale fishery. The town was founded in 1620 by Christian IV. It was formerly fortified, but its fortifications were demolished in 1814. It is connected by railway with Altona, Kiel, and Rendsburg. From this town is derived the name of Glückstadt, which was applied to the dukedom of Holstein. The famous academy of the town was closed in 1858.

GLUE. See GELATINE.

GLUTEN, or VEGETABLE FIBRINE, a tough elastic substance, named from its adhesive glue-like property, an ingredient in wheat especially, and in smaller proportion in most of the cerealia and in some leguminous plants. When wheat flour is well kneaded upon a sieve under a stream of water, the soluble starch and sugar are washed away and the gluten remains behind. This was supposed by Beccaria, who first noticed it, to be a distinct principle; but it is found still to retain a little starch, and other ingredients are separated from it according to their different reactions when treated with boiling alcohol. The pure vegetable fibrine is then found to constitute about 72 per cent. of the original gluten, while an albuminous substance called gliadine, vegetable caseine, and a vegetable oil make up the remainder. Gluten from rye flour contains very little of the tenacious ingredient, gliadine; and other grains furnish gluten of variable proportions of its ingredients. It is gluten which gives to the dough of wheat flour its peculiar tenacity, and it is owing to this that the escape of carbonic acid gas is arrested in the fermentation of wheat bread, and the product is consequently lighter and more spongy than other bread. Macaroni and vermicelli are preparations of gluten, and the flour of the south of Europe is said to be peculiarly adapted for this manufacture, as it generally contains a considerably larger proportion of gluten than that grown further north. The proportion, however, is variable in wheat of the same vicinity, and it may be increased by the use of animal manures, especially those most rich in nitrogen. Liebig noticed that wheat manured with cow dung (which contains but little nitrogen) produced 11.95 per cent. of gluten; while another portion manured with human urine yielded the maximum of gluten, 35.1 per cent. Summer wheat grown in the *jardin des plantes* at Paris was found to contain 26.7 per cent. of gluten, while a sample of winter wheat gave but 8.83 per cent. As gluten is the most nutritious ingredient in the grains, its proportion has been carefully estimated by chemists. Vauquelin found it in wheat averaging 11.18 per cent.; Dumas, 12.50 per cent.; and Dr. Lewis O. Beck, from 33 samples gathered from different parts of the United States, found an average of 11.72, the range being from 9.85 to 15.25 per cent. Prof. Horsford, by ultimate analysis of the wheat, instead of separation of the gluten by mechanical washing, obtained an average of 15.14 per cent. from 6 samples. Payen found the proportions of gluten and other nitrogenous matters in

wheat to range from 11.20 to 22.75 per cent.; in rye, 13.15; barley, 13.96; oats, 14.89; corn meal, 12.50; rice, 7.05. Prof. Johnston found in English fine wheat flour 10, in bran of the same flour 18, in Scotch oatmeal 18, and in corn meal 12 per cent. of gluten. It is found by very careful and repeated analyses that the bran of wheat and of most other cereals is richer in gluten, and consequently more nutritious, than the rest of the grain. Hence the preference for flour that by thorough bolting has been most completely deprived of bran is unwise; and the whitest flour is less valuable for its nutritive qualities than that made from the whole grain. The bran sometimes constitutes $\frac{1}{2}$ and more of the grain, and, according to the analyses of Prof. Johnston, contains 14 to 18 per cent. of gluten, while the fine flour contains only 10 per cent. Gluten is readily reduced in quantity, and its tenacity is diminished by injury to the grain. Flour dealers and bakers judge of the quality of flours by the tenacity of the dough made from a few grains of it. An instrument for determining the quality of gluten is described under ALEUROMETER.—The subject is further treated under ALIMENT, vol. i. p. 361.

GLUTTON, a carnivorous mammal, belonging to the family *mustelida*, sub-family *martina*, and genus *gulo* (Storr). The dental formula is that of the true martens, viz.: incisors $\frac{3}{1}-\frac{3}{1}$, canines $\frac{1}{1}-\frac{1}{1}$, premolars $\frac{2}{1}-\frac{2}{1}$, molars $\frac{1}{1}-\frac{1}{1}=\frac{3}{3}$, in all 38; the first 3 molars in the upper, and the first 4 in the lower jaw, are small, succeeded by a larger carnivorous tooth. In dentition and general structure the glutton resembles the martens; but in its shape, and partially plantigrade feet, it so much resembles a small bear that many writers have placed it among the *ursida*. The head is rather pointed and bear-like, the eyes and ears very small, the body long and stout, the legs short and robust, the claws large and sharp, the soles covered for the most part with bristly hairs, and the tail short and bushy. The glutton of Europe (*G. luscus*, Linn.) is about as large as a badger, of a deep brown color, darkest on the back. The voracity of this animal, as its name would imply, is great, though it has been much exaggerated. It is nocturnal, inhabits the coldest countries, as Russia and Siberia, and is active all winter. The American glutton, called also wolverene and carcajou, seems to be a paler variety of the *G. luscus*; the color is dark brown above, passing into black; a pale band runs on each side from the shoulder around the flanks, uniting on the hips; tail with long bushy hairs. The inner fur is soft and short, the outer long and coarse, like that of the black bear; across the forehead, on each side of the neck, and between the legs, are patches and tufts of white hairs. The average length to root of tail is 24 feet, the tail from 10 to 12 inches, and the height at shoulder about a foot; the width of the hind feet is nearly 5 inches, so that their tracks in the snow are not unlike those of the bear. The wolverene is confined almost exclusively to the northern

regions of the continent, being most abundant in the Rocky mountains near the arctic circle; it is occasionally seen in northern New York, and in the west has been found as far south as Great Salt lake. The strength, agility, cunning, and voracity attributed to the glutton by the older writers are mostly fabulous; it is by no means ferocious, is slow and heavy in its motions, not remarkably voracious, neither strong nor agile enough to pounce upon and kill deer and other large game, and avoids entering water in pursuit of prey. The wolverene generally hunts at night, spending the day in holes and caves; its food consists principally of small quadrupeds, such as mice, marmots, and other rodents, grouse and other birds which have plunged under the snow; there is no proof that it destroys the beaver, except occasionally; it may sometimes finish larger animals disabled by the hunter, by old age, or by accident, and when hard pressed will eat carrion. It is notorious for following the traps of the hunter, and stealing therefrom both the bait and the captured animal, and for digging up and destroying *caches* of provisions. The wolverene is very suspicious, and rarely caught except in carefully concealed steel traps; it is a very strong animal for its size, its weight being from 25 to 80 lbs. The young are produced once a year, 2 to 4 at a time. The fur of the wolverene is used for muffs and sleigh robes. The specific name *luscus* was given by Linnæus to an American animal, which happened to have but one eye; should the European glutton be separated from the wolverene, it would be properly called *G. borealis* (Nilsson).

GLYCERINE (Gr. $\gamma\lambda\upsilon\kappa\upsilon\varsigma$, sweet), the sweet principle of oils, the base of the compounds found in animal fats and also in some vegetable substances. Its composition is represented by the formula $C_3H_5O_3 = 2(C_2H_5) + O_2 + .HO$, the substance being generally admitted to be an oxide of a compound radical, named by Berzelius lypil, and by Löwig glycil, both of whom give it the composition C_3H_5 . It is a colorless, transparent, sweet sirup, without odor, of specific gravity 1.28; it is inflammable, mixes freely with water, taking it from the air, is also soluble in alcohol, but not in ether, and dissolves salts that are soluble in water; it does not become rancid by exposure, but with yeast may be made to ferment. At a temperature above 600° F. it is decomposed, being converted into acroleine, acetic acid, and inflammable gases. Between 500° and 600° it may be distilled with only partial decomposition. Berthelot has succeeded in causing it to combine with the fatty acids, and has thus produced the organic fatty substances, stearine, margarine, oleine, &c. This was effected by keeping the mixture of acids and glycerine at a temperature of 212° for several days in close vessels. At higher heat much less time is required to complete the process.—Glycerine is a product of the process of saponification. As prepared by the pharmacutists, it was taken up with boiling water from its mixture in a free state with the plumbiferous soap,

called lead-plaster. The plaster is made by boiling together litharge (oxide of lead), olive oil, and water. The oil is decomposed by the lead taking its acids, and the glycerine is thus liberated. When hot water is added in equal quantity to the plaster, the mixture is well stirred, and the liquid part is decanted; any lead that may be present is thrown down by a current of sulphuretted hydrogen, and is got rid of by filtering. The water is finally removed by evaporation at a temperature below 212°, leaving the glycerine. Various other methods of preparing it are however in use. The mother liquor of the soap factories affords a convenient source of it. From these it is separated by first adding a slight excess of sulphuric acid, heating the solution with carbonate of baryta, filtering, and, after the filtrate has been concentrated by evaporation, taking up the glycerine with alcohol, which is afterward to be distilled off. A hot solution of fat has been decomposed by injecting into it superheated steam. The fatty acids and glycerine, collected in a receiver, separate in two layers, the glycerine at bottom. The acids can be drawn off, so as to leave the glycerine with no other mixture than water. The method of detecting the presence of glycerine when in small quantity is based on the marked qualities of the substance acroleine into which it is in part converted by heat. If the substance supposed to contain it be separated from foreign mixture as far as possible and rapidly heated, either alone or with a little anhydrous phosphoric acid, the acroleine generated, in case glycerine was present, will be detected by the pungent acrid odor, somewhat like that from the wick of a candle just extinguished.—Glycerine has been esteemed of little importance until within a few years. It first came into use in medicine, being introduced into the ear when this was deficient in the secretion of wax. Its property of long continuing moist, while it is not of a greasy nature, suggested its application in certain diseases of the skin characterized by dryness and hardness; this was attended with satisfactory results. It is said to act upon urinary calculi, for which it is now prescribed. Poultices are long kept soft by the addition of $\frac{1}{4}$ to $\frac{1}{2}$ of this substance; and it is made a vehicle for administering other medicines, whose properties are disguised by dissolving them in it as in water. For use in cosmetics and perfumery it is now largely manufactured, its soft, agreeable qualities, without greasiness or liability to putrefy, rendering it an excellent ingredient in soaps for the toilet, pomade, hair tonics, &c. It is lately employed in the photographic art, and its use is extending for a variety of new purposes. A glycerine ointment of much repute for chapped hands and excoriations is made as follows: $\frac{1}{2}$ oz. of spermaceti is melted together with a drachm of white wax and 2 fluid oz. of oil of almonds, by a moderate heat; the mixture is poured into a Wedgwood mortar, when a fluid ounce of glycerine is added to it and rubbed till the ingredients are thoroughly mixed and cold.

GLYNN, a S. E. co. of Ga., bordering on the Atlantic, and bounded N. by the Altamaha river; area, about 400 sq. m.; pop. in 1850, 4,933, of whom 4,232 were slaves. The state census of 1855 exhibits no returns from this county. The surface is level and occupied partly by sandy pine barrens, partly by vast swamps, which when drained are productive. The sea island cotton grows here in perfection. Several islands on the coast, one of which is about 12 m. long, are included in the county. The productions in 1850 were 49,739 bushels of Indian corn, 55,100 of sweet potatoes, 3,829,875 lbs. of rice, and 1,036 bales of cotton. There were 4 tar and turpentine distilleries, 2 ship yards, 1 saw mill, 6 churches, and 176 pupils attending schools and academies. This county is one of the oldest in the state, having been formed in 1777, and named in honor of John Glynn, an English lawyer noted for his friendship toward the American colonies. Capital, Brunswick. Value of real estate in 1856, \$867,860.

GLYPTODON, a gigantic fossil mammal, belonging to the edentate order with the *megatherium* and *mylodon*, but to the family *dasyptida* or armadillos, found in the tertiary deposits of the pampas of South America, and especially in the neighborhood of Buenos Ayres. This animal, with the fossil genera above mentioned, establishes the transition between the sloths and the armadillos, and also indicates some pachyderm affinities. Very full descriptions of the species of glyptodon have been given by Prof. Owen in the "Transactions of the Geological Society of London," vol. vi., and in the "Journal" of the same society, vol. i. He describes 4 species, of which the largest is the *G. clavipes* (Owen); this species, in the structure of the foot and the articulation of the lower jaw, approaches the pachyderms; it resembles the megatherioids in the strong descending process of the zygomatic arch, compressed from before backward; the cranium was protected by dermal plates, and its well developed ridges indicate the existence of very powerful muscles. The teeth, 8 on each side of each jaw, have a large proportion of hard dentine, and are characterized by 2 lateral sculptured grooves, whose wide and deep channels divide the grinding surface into 8 portions; hence the generic name applied by Owen, which means "sculptured tooth." The back and sides were covered by a carapace composed of thick polygonal bony plates, united by sutures, smooth on the inside, rough and sculptured externally, to the number of more than 2,000. The length of the largest living armadillo, covered with a flattened shield, is about 8 feet; the size of the glyptodon may be imagined from the measurement of its carapace in the museum of the royal college of surgeons: the length, following the curve of the back, is 5 feet 7 inches—in a straight line, or the chord of the arc, 4½ feet; the breadth, following the curve, is 7½ feet—in a straight line, 8½ feet. The tail measured 1½ feet in length, and 14 inches in circumference at the circular base; it was slightly depressed toward

the apex, and gently curved, with the concavity upward; the caudal vertebrae were enclosed in an inflexible sheath of bony plates, terminated by 2 ossicles, like a bivalve shell, enabling it to pierce the soil if necessary. The feet were short and stout, armed with depressed nails. The glyptodon, in its firm, convex carapace, scale-covered tail and head, short limbs, and consequent slow motions, presents many external analogies to chelonian reptiles, and in its size and shape must have resembled rather the living Galapagos tortoise than the great armadillo. Like the living armadillo, the extinct glyptodon was confined to the warm parts of South America. Other species described by Owen are *G. ornatus*, *G. reticulatus*, and *G. tuberculatus*, all obtained from the vicinity of Buenos Ayres.

GMELIN. I. JOHANN GEORG, a German naturalist and traveller, born in Tübingen, June 12, 1709, died there, May 20, 1755. In 1781 he became professor of chemistry and natural history at St. Petersburg, and in 1788 started on a scientific journey through Siberia, with a number of distinguished companions, at the expense of the government. He traversed Siberia in every direction, and returned to St. Petersburg after an absence of nearly 10 years. In 1749 he accepted the professorship of botany and chemistry in his native city, which office he held till his death. His *Flora Sibirica* (4 vols., St. Petersburg, 1749-'70), and his "Journey through Siberia" (4 vols., Göttingen, 1751-'2), are his principal works. II. SAMUEL GOTTLIEB, nephew of the preceding, born in Tübingen in 1744, was appointed professor at the academy of St. Petersburg, travelled through southern Russia, and died at Akhmetkent, in the Caucasus, in 1774. His "Journey through Russia," a scientific work, is his chief publication. III. JOHANN FRIEDRICH, nephew of Johann Georg, born in Tübingen in 1748, travelled through Germany, Holland, and Belgium, and was appointed professor of chemistry and medicine at Göttingen, where he died in 1804. He wrote voluminously on the natural sciences, but he is chiefly known as editor of the 18th edition of Linnæus's *Systema Naturæ*.

GNAT, a name commonly given to the family *culicida*, of the proboscidean division of the order *diptera* or 2-winged insects—the *cousin* of the French, the mosquito of the United States. The gnats belong to the genus *culex* (Linn.), which is characterized by a soft, elongated body; long legs; large head and eyes; long, many-jointed antennæ, most plumose in the males; filiform and hairy palpi, longest in the males; a sucking proboscis, formed of a membranous sheath enclosing from 2 to 6 sharp bristles or lancets, which take the place of jaws, and whose punctures, therefore, are properly called bites; the side pieces of this apparatus serve not only as suction tubes, but as supporters and protectors of the lancets; wings horizontal, delicate, and many-veined; the winglets, 2 little scales behind the wings, and moving with them, are small; behind these are the knobbed balancers

or poisers. The old genus *Culex* was divided by Meigen into 3, and was by him restricted to such gnats as have the palpi in the males longer than the proboscis, and very short in the females; the other 2 were *Anopheles* (Meigen), in which the palpi of the males are as long as the proboscis, and *Aedes* (Hoffmannsegg), in which they are very short in both sexes; to these were afterward added *Sabethes*, with palpi shorter than proboscis; *Megarhinus*, with very long recurved proboscis and short palpi; and *Peorophora*, with a small appendage on each side of the prothorax. Other genera, ill-characterized for the most part, have been added by modern systematists; but the whole family is very little understood. The names gnat and mosquito are also given in some places to members of the family *Tipulidae*; and our own mosquitoes belong to several genera, among which is the genus *Culex*, properly confined to the more northern regions of the continent. No attempt will be here made to introduce order into the mosquito chaos; but the common gnat (*C. pipiens*, Linn.) will be taken to illustrate the curious metamorphoses and habits of this bloodthirsty family. Dr. Harris mentions 5 species of *Culex* and one of *Anopheles* as found in New England; to these many species and several genera must be added, when we consider the vast extent of this country. Some species are active by day, others only by night, but both are equally fond of human blood; the former are found principally in marshes and damp woods, and rarely in houses, and are of more brilliant colors than the nocturnal species. The males with plumed antennæ do not annoy us by their bites, but simply flit from flower to flower, sipping the dew and sweet juices, requiring but little if any food, propagating their species, and soon after perishing. Every one's experience proves that the female gnats are most persistent biters and annoying musicians, at almost all seasons of the year; from the tropics to Lapland and arctic America, man is obliged to adopt some contrivance to protect himself from their attacks—either the thick coat of grease of the northern regions, the sand bed of the tropics, the smoky smudge of the woods, or the mosquito bars and curtains of civilized life. Gnats have been known to appear in such swarms as to constitute an insect plague, darkening the air like clouds of smoke, arresting the progress of invading armies, and rendering whole districts for the time uninhabitable; attacking not only man but beasts, and, even when not biting, filling every crack and corner with their countless multitudes. When we consider the immense number of these insects, and the comparatively small proportion which can ever taste human blood, we must admit, what experiments with sweetened fluids have confirmed, that vegetable juices form the food of the greater number of females, and perhaps the natural food of all; many males probably do not eat at all. The sucking apparatus is admirably contrived for obtaining fluids, animal or vege-

table, and these insects are provided with a sucking stomach independent of the proper digestive cavity. The sucker in all its essential parts has been well described and figured by Réaumur in his "Memoirs;" the flexible sheath gives support to the lancets while they penetrate the skin; the point of the combined lancets is sharper than the finest needle, so that the size of each of the several weapons must be very small; the wounds made by this instrument would be insignificant, were it not for an irritating secretion from the proboscis, which in some delicate skins produces obstinate itching, considerable redness and swelling, and, in rare instances, even irritable ulcers.—The metamorphoses which gnats and mosquitoes undergo are very curious, and especially interesting for the ease with which they may be seen. The eggs are deposited in almost any natural or artificial receptacle for water, and are arranged in a boat-shaped form; fixing herself by the 4 anterior legs to some object at the surface of the water, the female crosses her hind legs in the form of the letter X; bringing the latter close to the end of the body, on a level with the water, the first egg is received and retained in place by the crossed legs; as the eggs are extruded they are placed side by side vertically, adhering firmly together by the glutinous substance which covers them; when the stern of the egg raft is properly raised, it is pushed further from the body by the succeeding ova, always retained in place by the legs on the sides; when the raft is about half made and its shape is determined, the legs are uncrossed and placed parallel, and the prow of the boat is narrowed and raised like the stern. The boat is always of the same shape, containing from 250 to 350 eggs, and is abandoned by the mother to the mercy of the winds and waves, which can neither sink, wet, nor break it up; even a temperature below freezing cannot destroy the life within these eggs. The larvæ come out in a few days from the lower end of the eggs, which are arranged somewhat like the seeds of the ripe sunflower, and the empty shell boat is soon destroyed by the weather. The larvæ of gnats and mosquitoes are the well-known "wigglers" seen in warm weather in almost every collection of standing water; they remain, as it were, suspended from the surface of the water, head downward, breathing air by means of a respiratory tube which goes off at an angle from near the end of the body, communicating with the tracheæ; the tube and the terminal joint are provided with radiating hairs; the head is round, distinct, with antennæ and ciliated organs which keep up a constant current of water toward the mouth, and bring within their reach the minute animalculæ on which they feed; the thorax and 10-jointed abdomen are furnished with lateral pencils of hairs. If disturbed, these larvæ quickly wriggle to the bottom, but soon come again to the surface and suspend themselves by the respiratory tube. Some species are comparatively free from hairs in

this condition. After remaining in the larva state from 5 to 15 days, according to the weather, and changing their skins 2 or 3 times, they are changed into pupæ, called tumblers from the manner in which they roll over and over in the water by means of the fin-like paddles at the end of the tail; they are very quick in their motions, and swim with the head upward; the respiratory openings are at the end of 2 tubes situated just behind the head, so that the little tumblers remain near the surface, head upward, to take in air; in this state, which lasts 5 or 10 days, according to circumstances, the insect takes no food; the future gnat can be distinguished through the transparent covering of the pupa. When the perfect insect is ready to come forth, the pupa skin bursts open on the back toward noon on a warm, still, sunny day, and the head of the gnat makes its appearance, followed soon by the thorax; this is a process of great danger to the insect, as the slightest breeze would tip over the emerging form, and consign it to certain death in the water; after it has succeeded in raising its body except the tail, and stands erect like a mast in the pupa shell boat, it extricates the front pair of legs and places them for support on the surface of the water; the heavy and wet wings are now slowly unfolded, that the sun and air may dry them; this effected, the danger is over, and the other legs are drawn forth and extended on the edge of the pupa case, the body is stretched out, the antennæ and proboscis elevated; by this time the wings are dry and fully expanded, and the insect flies off to revel among the flowers or in search of blood, according to the sex. The source of the buzzing noise, which to many is more annoying than their bite, has been much discussed by naturalists, and is still the subject of dispute; it has been ascribed to the mouth by Mouffet, to the friction of the base of the wings against the chest by Kirby; the winglets, the poisers, the motion of the wings, the rapid passage of air through the thoracic stigmata, and the vibrations of the thorax from the contraction of the muscles of the wings, have been supposed to be the cause by other entomologists; by whatever organ it be produced, Siebold says it is always due to the action of voluntary muscles, and has no connection with the respiratory system. It is probable that the sound is produced by the combined action of the wings and by the thoracic vibrations consequent thereon. It has been estimated by Baron de la Tour that the gnat vibrates its wings 50 times in a second. This very rapid movement probably depends on a peculiar form of muscle which has been detected in the mosquito and other *diptera*; the fibrillæ are not bound together as in ordinary striated muscles, but are separate and parallel, formed by the aggregation in a linear series of little disks with regular interspaces; contraction of these independent fibrillæ takes place by the approximation of these disks to each other; some are contracting while others are relaxed, so

that a constant and rapid movement of the wings is secured. It is certainly a remarkable example of the extent of modern microscopic investigation, that the minute muscles of the wings and legs of the mosquito can be dissected and studied. All the biting *culicids* do not make a boat of eggs; some string their ova end to end, others deposit them in soft mud or in dry sand; but all require moisture in the larval state. As the eggs are developed into the perfect insects in about 8 weeks, many broods are hatched in the course of the warm season, fully explaining their occurrence in large numbers; fortunately only a small portion of the pupæ succeed in extricating themselves from their cases; thousands of them perish by drowning, and are devoured by fish, reptiles, and aquatic insects; the perfect gnats supply food for carnivorous insects, the great tribe of fly-catching birds, and the bats.—The family of *tipulids* are also called gnats; these are often seen performing their aerial dances during the summer, and in sheltered places even in mild days in winter, preferring the decline of day; these dancing companies are said always to consist exclusively of males; any attempt to intrude upon their sportive circles shows their quickness of vision and of motion, as the whole company is at once removed to a distance. These gnats are sometimes produced in such numbers as to prove exceedingly annoying; they crowd into houses, fly into articles of food, extinguish candles, and fill up every opening, even the human mouth, nose, and ears, forming one of the most common insect plagues.

GNEISENAU, August, count, a Prussian general, born in Schilda, Oct. 28, 1760, died in Posen, Aug. 24, 1831. He first took service in the Austrian army, and subsequently in that of the prince of Anspach Baireuth, with a detachment of whose troops he was sent to America to serve under the English, shortly before the close of the war of American independence. He returned after the peace, and entered the Prussian army, where he was made captain in 1789. In 1794 he fought against the Poles, and after the disastrous battle of Saalfeld in 1806, and the reverses which followed it, he organized a battalion of reserves, was appointed commander of the fortress of Colberg (1807), repelled the assaults of the French, and held the place till the peace of Tilsit. The resentment of Napoleon caused his removal from the army (1809), but he received several secret missions to Vienna, St. Petersburg, Stockholm, and London. Afterward he was attached to Blücher's army as quartermaster-general, and subsequently as chief of the staff. (See BLÜCHER.) He took a leading part in the eventful Silesian campaign of 1812, and after the battle of Leipzig he was made lieutenant-general. He was also zealous in the organization of the patriotic *Tugendbund*. His activity was no less important during the campaign of 1814 in France, both on the battle field and in the council of commanders. He is said to have advised the march to Paris, which

overthrew the first empire. The title of count, the rank of general, and an estate yielding an annual income of 10,000 thalers, were his reward after the peace. After the return of Napoleon from Elba he again served with Blücher, and effected, while the old commander was disabled, a skilful retreat from the battle field of Ligny (June 16), thus enabling the Prussians to reappear at Waterloo (on the 18th), and to decide the fate of the campaign. He now took part in the negotiations for peace, was made commander of the Rhenish corps, and accompanied Blücher to England. Disappointed in his expectation of constitutional liberty, as promised by the princes of Germany during the war, he tendered his resignation, which was conditionally accepted. In 1818 he was appointed governor of Berlin and member of the state council, and in 1825 he received the rank of field marshal. When the revolution of Poland seemed to take a threatening aspect in 1831, he received the command of the army in the eastern part of Prussia, soon after which he died of the cholera.

GNEISS, one of the metamorphic rocks, of the same composition with granite, from which it differs in presenting the 8 ingredients, quartz, mica, and feldspar, in tolerably distinct layers. The whole mass is often divided into distinct beds or strata, and these exhibit a tendency to cleave along the planes in which the mica is most largely distributed. Gneiss by gradual change of structure becomes granular, and then cannot be distinguished from granite. By increased proportion of mica and loss of feldspar, it passes into micaceous slate. The name gneissic is sometimes given to the group of metamorphic rocks, including the micaceous and hornblende slates, quartz rocks, &c. They are also called hypozoic in reference to their position beneath the fossiliferous strata. The series is familiarly known in the eastern and middle states, ranging through Vermont, Massachusetts, the S. E. part of New York, through northern New Jersey, eastern Pennsylvania, Maryland and Virginia, &c. The gold region lies in this group.

GNESEN (Pol. *Gniezno*), a town of Prussia, in the duchy of Posen, the seat of an archbishop; pop. about 7,500. It was the capital of Poland from the foundation of that state till 1820, when Cracow became the capital. The archbishops of Gnesen were the primates of the state, and officiated as vicars during the often long disputed elections of the kings. Gnesen was often besieged, taken, and pillaged.

GNIEDITCH, NICOLAI, a Russian poet, born in Pultowa in 1784, died in St. Petersburg, Feb. 1838. He devoted 18 years to the translation of the Iliad into Russian, and furnished beside translations from the writings of Anacreon, Voltaire, Byron, and of other authors. The most celebrated of his original poetry is an idyl, *Ribaki*, or "The Fishermen."

GNOME. See PROVERB.

GNOMES, in the fanciful systems of demonology, one of the 4 classes of elementary spirits, composed of the subtlest parts of the earth, as

the salamanders were of fire, the sylphs of air, and the undines of water. The earth, it is said, is filled to its centre with gnomes of aërial stature, both male and female (the latter are called *gnomides*), and both mischievous and beneficent, who guard its mines, precious stones, and all its treasures. They were believed to furnish to alchemists and cabalists all the gold and silver needful to them. They nearly correspond, in learned and scientific treatises, to the dwarfs and kobolds of popular tradition.

GNOSTIOS (Gr. *γνῶσις*, knowledge), a body in the early Christian church, reckoned by most writers among the heretical sects. Locally, most of the Gnostics belonged to the Egyptian and eastern churches, and their opinions had comparatively little influence on the churches of Italy and the West. They were most numerous in Asia Minor and Syria. Yet Hippolytus, in the *Philosophoumena* generally attributed to him, assigns to many of their speculations a Grecian origin, insisting that not the opinions of Plato only, but of Aristotle, Pythagoras, Heraclitus, and Empedocles, appear in the theories of the principal Gnostic teachers. According to most authorities the Gnostic heresy began to show itself even in the time of the apostles. Simon Magus pretended that he was an emanation of God; and several passages of the epistles of Paul, and of the epistles ascribed to Peter, John, and Jude, seem to be suggested by Gnostic views. The testimony of the Apocalyptic writer is still more decided. A legend of the church tells us how St. John turned his back upon Cerinthus, whom he met in the bath at Ephesus, and a current tradition affirms that John wrote his Gospel to confute this heretic. The fathers, however, are divided as to the character of the heresy of Cerinthus. While many pronounce him a Gnostic, some will have it that he is a Chiliasist. The flourishing period of Gnosticism was the 2d Christian century. In the 3d century it was to a considerable degree supplanted by other heresies, especially by the kindred heresy of Manicheism. Some of its schools were nearly extinct in the 4th century, and in the 6th century the Gnostics are no longer spoken of as a sect, although traces of their opinions are still to be found.—There are 8 principal theories of the character of Gnosticism. Banr treats it as a "philosophy of religion," resulting from the comparison of various religious systems. Neander treats it as a fusion of Christian ideas with oriental theosophy, caused by the prevalence of sensuous ideas within the church. Möhler would have it to be an intense and exaggerated Christian zeal, seeking some practical solution of the problems of sin and evil. All minor theories of the purpose and motives of Gnosticism can be comprehended in one of these; and these 8 would agree in the general definition, that Gnosticism is an attempt to solve the great problems of all theology by combining the elements of pagan mysticism with the Jewish and Christian traditions. It is impossible to make

a quite accurate definition of a system of which the speculations are so vague, and the materials for judgment so scattered and fragmentary. There is no evidence at any time of unity either of opinion or action in the Gnostic party. Different writers vary widely in their method of classifying the various Gnostic schools. Some classify them by opinions, some by origin, and some by locality. Neander makes the force of opposition to Judaism the test of his discrimination among the Gnostics. Gieseler divides them into 2 classes, those who are dualists, and those who are emanationists. Matter, the French historian of Gnosticism, reckons 4 classes, the Gnostics of Syria, of Asia Minor, of Egypt, and of the rest of the Roman world. Hase numbers 3 classes, Hellenistic, Syrian, and Christian Gnostics. Baur divides the sects into Valentinians, who prefer paganism, Marcionites, who prefer Christianity, and the pseudo-Clementine party, who prefer Judaism, in their theosophic discussions. And still another ethical division, suggested by Schaff, gives the 3 classes of "speculative and theosophic," "practical and ascetic," and "antinomian or libertine." With such wide differences of classification, it is difficult to discover the essential teachings of Gnosticism, or to combine the shades of doctrine of the different schools. The general characteristics of all the classes cannot be gathered into exact statements. All Gnostics are not dualistic, nor do all hold the Docetic heresy.—The average doctrines of the Gnostic sect, as they are set forth in the writings of their opponents, are as follows: 1. Concerning God. The Gnostics remove God infinitely far from the world, enclose him in the "Abyss" (*Bador*), with which indeed he is confounded, separate him from every work of temporal creation, and leave him uncomprehended and incomprehensible by any mortal. He only communicates with the lower world through the medium of the *æons*, which he sends forth from his grand solitude. The Gnostic God has infinite development in the forces which he sends, but no personal or special providence. He is the sum of being, yet the extreme of abstraction, and is even called the Not Being (*οὐκ ὂν*). 2. The Pleroma. Below the abyss, in which God alone dwells, or surrounding this abyss, is the Pleroma, or fullness, that world of light and glory which the *æons* inhabit. These *æons* are emanations from God's central fullness, are embodiments of his divine attributes, and fulfil the functions denoted by their several names. They are called *æons* because they are the representatives of the Eternal. Only the first of these *æons*, Nous, or Mind, proceeds directly from the bosom of Deity. The other spirits of the Pleroma emanate in descending succession from the first *æon*. Reason, Wisdom, Power, Truth, Life, are the names of the higher. These *æons* are variously numbered and classed. According to Valentinus, they are of different sexes and go in pairs. Another writer reckons the number of supe-

rior *æons* at 365. Only the lowest *æon* has any communication with the material world, and he is at the point where the two worlds touch each other. The business of the *æons* is to people and to care for the spiritual world. To show the reasonableness of this emanation theory, Saturninus uses the illustration of numbers developed from an original unit, while one of the three known by the name of Marcus compares the emanation of *æons* from God to the tones of the voice lessening steadily to a faint echo. 3. The Demiurge. The Gnostics regarded matter as infinitely separated from God, and the material world as the antithesis of the spiritual world. Hyle, or matter, is either absolute deadness and emptiness (*κενωμενα*), or is a positively evil substance. The creator of this material universe is the Demiurge. He is himself a creature of the lowest of the *æons*, Ahamoth. He not only creates and rules the terrestrial world, but has equal sovereignty over the planets and stars. He fulfils unconsciously, according to some, and according to others defiantly usurps, the functions of the infinite God. He appears in Jewish history as Jehovah. Other names by which he is known are those of Arohon and Jaldabaoth, the son of chaos. The immediate work of the Demiurge is evil, and it takes the world of man and matter further away from God and the world of light. 4. Human nature. Man, according to the Gnostics, has a threefold nature, of spirit, of body, and of soul. His soul nature stands between the other two, and forms their connecting bond. They divided men into 3 classes, according to the predominance of one or other of these 3 natures. The highest or spiritual class were the Pneumatici; the lowest or carnal class were the Sarkici, or Physici, or Hylci; the intermediate class were the Psychici. The first of these classes were privileged to enjoy a light from the world of *æons*; the second were left wholly to material and hylc influences; while the third were under the direction and influence of the Demiurge, who could save them from utter debasement, but was not able to give them spiritual life. Historically, the Christians constituted the Pneumatici, the pagan world the Physici or carnal class, and the Jews occupied the intermediate place. But in dividing the Christians of their own time, the Gnostics numbered two classes, the select few of their own number who were admitted to the divine secrets, and the large body of common believers, who were not able to rise above the psychical condition. Some of them maintained that though man as connected with matter is by nature sinful, and though the Demiurge had wished to create man in his own image, yet unconsciously he reproduced in this work of his breath, not his own image, but a shadow of that divine original which moved before his imagination. Man is better than the intention of his creator. 5. Redemption. The subjects of redemption, according to the Gnostics, are only the pneumatic and psychic classes; the carnal or hylc class

are destined to annihilation when their material life shall close, and with them such of the psychic class as have not accepted the influence from the Pleroma. The instrument of redemption is the *æon* Christ. This *æon* comes down from the spirit world, assumes bodily shape without being actually united to any material body, and walks among men in Judæa as Jesus of Nazareth, not a real human person, but an optical illusion, the phantasm of a spiritual idea. Some of the Gnostics were willing, indeed, to speak of the human life of Christ; but all denied that his body was like that of other men, composed of the elements of corrupt and sinful matter. Christ's body was an ethereal body of more delicate fabric than the common human body. Hunger would not impel him to eat, nor thirst to drink. Yet this fine ethereal body was too gross for the Pleroma, and was left in the sun at Christ's ascension. The advent of Christ upon the earth was not the birth of a prophet, or the coming merely of a promised Messiah, but a spiritual apparition to overthrow the work of the evil spirit—"an incarnation of the spirit of the sun." The presence of Christ anywhere made men conscious of this divine nature. They might doubt of the humanity of Christ, but not of his divinity. The process of redemption, in the Gnostic theory, is the communication through the *æon* Christ of a divine life to the world of man, the revelation of that life through this mediator. Christ redeems the world as he draws the spiritual in the world toward the heaven of God. His sufferings and death have no influence in the redeeming work, since, in the first place, they were illusory, and in the second place, sufferings do not redeem, but only punish. The manifestation by his acts and words of the spirit of God made Christ the redeemer. Some expressions were found in Gnostic writings which might be interpreted as teaching views of redemption more in harmony with the church creeds; but nowhere in their writings was any doctrine of atonement stated, or any stress laid upon the crucifixion as its central point. Marcion extends the redemption into the world of Hades, and maintains that Christ descended into hell to lead back the virtuous and believing heathen to share salvation with the spiritual Christians; but his view in this article of faith was not universally adopted. In regard to the means of profiting by the redemption of Christ, the Gnostic teachers were not agreed. Marcion taught a doctrine resembling that of Paul, making faith the means of justification and the ground of reconciliation. But most of the sect held that only "gnosis," the rare superior intelligence and comprehension of divine truth, could enable men to receive the gift of Christ. This spiritual science was the evidence of salvation to believers. The actual manner of union between Christ and his redeemed ones was very vaguely described in the Gnostic writings. They are hampered continually by their Docetic notions of the nature of Christ, and their language in speaking of re-

demption and its issues is confused. 6. The church. It was charged against the Gnostics by the Alexandrine Clement, "that they boasted of superintending schools rather than churches." Yet they held to a church, which should have a twofold life, for the mass of believers, and for the initiated; for those, common exoteric doctrines, and for these, spiritual esoteric doctrines. Like the Druses of modern Syria, the Gnostics recognized a sacred secret society within the proper circle of the church. Practically they had little talent for organization, and many of them were content to theorize about spiritual truth, while submitting to the recognized ecclesiastical order. Baptism was to them the important rite, since Jesus became Christ at his baptism, and through this rite the higher spirit was imparted to the sensuous soul. It was the sign of their emancipation from demiurgic rule. A few spiritual puritans objected to baptism as too physical a rite, but most of the Gnostics celebrated it with great show and solemnity. The Lord's supper was to them of less importance, being only the sign of a material feast, on the reality of which their views of the nature of Christ threw doubt. Some of them kept the feast days of the church, and the followers of Carpocrates allowed the use of images both of Jesus and the saints. While the idea of the church was to a great extent discarded, much of its ritual and its splendor was retained. 7. Practical morality. Two tendencies in practical morals are to be observed in the Gnostic schools. On one side is the ascetic tendency, which seeks a complete emancipation from matter and from bodily passion, as the seat of sin; on the other side the licentious tendency, which plunges into all sorts of excess, on the plea that sensual passion is most surely overcome by satiety, and that much fleshly indulgence will best vindicate the supremacy of the spirit. Many of the charges, however, brought against this latter class of Gnostics are to be taken with large abatement; and the assertion of Epiphanius that the Gnostic sects revived in Egypt the old Phallic worship is to be received with caution, as one of the many scandals of that credulous writer. There is no evidence that the average morality of the Gnostics was below that of the orthodox Christians, or that the ascetic tendency was carried to such extremes among them as among the Jewish Essenes or the later Christian hermits. Gnosticism, in the 2d century at least, was rather a speculative than a practical heresy, a system of intellectual vagaries rather than of moral corruptions.—In speaking of the principal Gnostic teachers, the geographical division may be adopted as most convenient, if not most philosophical. Of the precursors of Gnosticism before the formation of its principal schools are mentioned Euphrates, a half-fabulous person, only known by allusions in 2 or 3 passages of Origen's writings; Simon Magus, whose authentic history is related in the Acts, but of whom legends abound; Menander, the leading

successor in Simon's school, who asserts that his disciples enjoy an immediate earthly immortality, that they never die and never grow old; Cerinthus, who was a believer in the millennium, and in the human birth of Christ; Nicolaus, of whom nothing certain is known, except that he founded the sect of Nicolaitans, noted for their lax and reckless morality. Of the Syrian school, the chief characteristic of which is dualism, the principal teachers are: 1. Saturninus, who lived at Antioch about A. D. 125, in the reign of Hadrian. He maintains that the lowest æon is formed from the spirits of the 7 planets; that the evil spirit formed a race of hylic men to counteract the race of psychic men formed by this æon; and that Christ is the æon Nous in a visible but not corporeal body. His school, never very numerous, was confined to the neighborhood of Antioch, and was hardly known in the succeeding century. It was characterized by intelligent and clear expositions of Scripture, and by rigor of life, avoiding marriage and animal food. In this school the Christian element was more conspicuous than the Jewish or the pagan. 2. Bardesanes, who flourished about A. D. 161, in the city of Edessa, where he was the trusted friend of King Abgar. He was a scholar of large attainments, versed in the literature of Greece, Chaldea, Persia, and India, the author of hymns which remained in favor with the eastern church for many centuries, unblemished in character, and inflexible in his hostility to paganism, as was proved by his controversy with the sophist Apollonius. His system is one of Christian allegory and poetic mysticism, dividing heaven and the Pleroma by "syzygies," maintaining the free will of the moral man, and giving the Holy Spirit to Christ, as at once sister and wife. His successors in the school were his son Harmodius, also a hymnist, and Marinus, one of his most learned and sagacious disciples. This latter taught a system of fatalism. The followers of Bardesanes received the books of the sacred canon, were always desirous to be reckoned orthodox, and were pure in life in spite of the demoralizing tendency of some of their views. The school was widely extended through Syria, and lasted until the 5th century. 3. Tatian, who is by many reckoned with the Syrian school, though he was a rhetorical teacher in Rome. He was converted by Justin Martyr. His theories were dualistic. One of his books, the *Oratio ad Græcos*, written in Greek, remains. He was the reputed founder of the sect of Encratites, which flourished in the 3d century. —In the Egyptian school, characterized by the emanation theory, the principal teachers are: 1. Basilides of Alexandria (125-140). The chief peculiarities of his system are its use of mystic numbers and names—the "ogdoad" or upper heaven, the "hebdomad" or lower heaven, the "alvaxas," or series of 365 circles of creation—its two demiurgi, and its threefold Christ. It made more account of faith than other Gnostic systems. The school of Basilides accepted also parts of the sacred writings, adding to them

various apocryphal books. It was large in numbers, respectable in influence, but not remarkable for Christian zeal or for excellence of life. After Basilides its most distinguished leader was Isidorus, his son, who made a system of ethics. 2. Valentinus, an Alexandrian Jew, who taught in Rome about the middle of the 2d century, and died in Cyprus in the year 160. His system of æons is divided into 8 series of 15 pairs, an ogdoad, a decad, and a dodecad. They are male and female. His "threefold Christ" differs from that of Basilides. His elaboration of Gnostic ideas was more complete and ingenious than that of any other writer, and his influence was longer and wider in its extent. Matter numbers 7 distinguished names among the successors of Valentinus, 5 of whom founded schools; these are Secundus, Ptolemy, Marcus, Colarbasus, Heracleon, Theodotus, and Alexander. 3. The Ophites, a powerful sect, yet without any distinguished name among their teachers. They pretended to be earlier than the time of Christ, and they existed at a later period than the other Gnostic sects. As their name implies, the serpent was for them a sacred emblem. They regarded the fall of man as a progress rather than as a loss, named the Jewish Jehovah "Jaldabaoth," or the God of chaos, preferred Judas to the other disciples, affirming that he betrayed Christ to destroy the kingdom of God's enemy, and denied that the real Christ was ever crucified. The Sethites and Cainites were branches of this sect. The moral character of the Ophites was bad, and the sect came, not only under the constant rebuke of the church teachers, but under the imperial ban.—Of the Gnostics of Asia Minor, the one eminent name is that of Marcion, an austere moralist, and a vigorous reasoner. He taught at Rome about the middle of the 2d century. His system is characterized by the constant antithesis between Christianity and Judaism, by a scornful rejection of the Old Testament, and of all apostolic authority except that of Paul, and by a rigid asceticism. His followers were numerous even to the time of Mohammed. Marcus, Lucan, and Apelles were prominent among them. Of the Gnostics not localized, but mostly related by their doctrines to the Gnostics of Egypt, may be mentioned the schools of Carpocrates and Epiphaneus, the Antitactas, the Bortonians, the Phibionites, the Arochontes, the Adamites, and the Prodicians. Hermogenes of Carthage is also by some regarded as a Gnostic teacher.—While the particular sects and schools of the Gnostics had disappeared almost wholly in the 6th century, their opinions survived to a much later age, seriously affecting not only the orthodox faith, but appearing in many of the famous and troublesome heresies. Their earlier influence is to be noticed in the views of the Ebionites and the Docetæ, in the speculations of the Clementine Homilies, in the radical theories of Montanism, in the fantasies of the New Platonists, and above all in the powerful and wide-spread Manichean heresy. Some have also endeavored to find traces of Gnosticism in

the Sabellian, Arian, and Pelagian heresies. In the 7th century their doctrines were repeated by the Paulicians, in the 9th by the Athingians, or "children of the sun," in the 11th by the Cathari, and in the 12th by the Bogomiles of Byzantium. Some of the opinions of the knights templars and of the Waldenses seemed to be borrowed from this source, and the reveries of Spanish and German mystics are not unlike the hymns of Bardesanes.—The most important works which treat of Gnosticism are: Neander, *Genetische Entwicklung der vornehmsten gnostischen Systeme* (Berlin, 1818); E. A. Lewald, *De Doctrina Gnostica* (Heidelberg, 1818); Möhler, *Ureprung der Gnosticism* (Tübingen, 1831); Baur, *Die Christliche Gnosis oder Religionsphilosophie in ihrer geschichtlichen Entwicklung* (Tübingen, 1835); Matter, *Histoire critique du gnosticisme* (2d ed. 3 vols., Paris, 1843-44); Jacobi, article in Herzog's *Real-Encyclopädie* (Stuttgart, 1856); and the church histories of Mosheim, Neander, Gieseler, Hase, and Schaff. Beausobre's "History of Manichæism," Münter's "Ecclesiastical Antiquities," Ritter's "History of Philosophy," Dorner's "Christology," and Bunsen's "Hippolytus and his Age," as well as the numerous German histories of dogma, contain acute criticisms of Gnostic opinions.

GNU, a hollow-horned ruminating animal, inhabiting the plains of southern and central Africa, generally classed with the *bovidæ* or ox family, of the genus *catoblepas* (H. Smith); the *wilde beest* of the Dutch colonists at the Cape. This is one of the most singular of animals, having the head and horns of a buffalo, the body and mane of a horse, and the limbs of an antelope. The form of the head, neck, and shoulders is decidedly bovine, robust, and clumsy; the forehead wide and flat, the muzzle broad, and covered with hair except the valvular opening of the nostrils; the eyes large; ears long, narrow, and pointed; horns present in both sexes, above and behind the eyes, close together at their origin, descending at first downward and outward, then curving upward and backward, flattened at the base, cylindrical at the tip, rough and irregular. The hair on the brows and forehead is long and shaggy, giving a fierce expression to the face; the neck has a rigid mane above, and a long, hairy dewlap below; the shoulders are deep, and surmounted by a moderate hump; the body is rounded like that of a horse, and the limbs delicately formed; the tail is moderately long, with a brush at the end; the hair elsewhere on the body is short; the hoofs are rather large for the limbs, and the skin of the knees is bare and callous, from their habit of going on their knees in attack and defence. The general color of the common species (*G. gnu*, H. Smith) is yellowish tawny, darkest on the back and legs, with the tips of the long hair blackish. The gnu, though clumsy in appearance, is very swift and active, galloping over the plains like a horse, and feeding in large herds like wild cattle; when alarmed, it rarely

takes to flight until it has examined into the cause of the danger, a curiosity of which the hunter is able to take advantage; it is very pugnacious, and tamed with difficulty. The common species is about 3 feet 10 inches high at the shoulders, and 6½ feet long from nose to tail. A second and larger species is the *kokoon* or brindled gnu, *blauwe wilde beest* (*C. taurina et gorgon*, H. Smith), which measures about 5 feet at the shoulders, and 7½ feet from nose to tail, the tail 1½ feet, and the horns about 2 feet long. The face is blackish, the sides of the head and neck yellowish gray, the latter and the shoulders with vertical dark stripes; the body above and the sides glossy reddish gray; below, and the limbs, reddish brown. Both species inhabit the extensive grassy plains of central Africa, advancing southward after the summer rains to the Orange river, south of which only the common and first named species ranges. Great numbers are killed every year by the Cape colonists, but their annual visitations still continue; the flesh is considered excellent.

GOA, a Portuguese territory of Hindostan, in the ancient province of Bejapoor, on the W. coast, between lat. 14° 54' and 15° 45' N., long. 73° 45' and 74° 26' E.; bounded N. by the native state of Sawuntwaree, E. by the British districts of Belgaum and N. Canara, and S. W. by the Indian ocean; length 62 m., breadth 40 m.; pop. 313,262. It is well watered and fertile, producing rice, pepper, cocoanuts, betel nuts, and salt. The inhabitants, ¾ of whom are Roman Catholics, are chiefly descendants of Europeans by native women.—OLD GOA, a city of the above territory, and formerly capital of the Portuguese possessions in India, is situated on an island separated from the mainland by the navigable river Mandova, 260 m. S. S. E. from Bombay; pop. about 4,000. Its houses are built of stone in the European style, its streets are regular, and its public buildings far surpass every thing else erected by Europeans in India, but are falling to decay. The inhabitants are chiefly ecclesiastics, and the aspect of the whole place is inconceivably desolate. It is the see of an archbishop, and has a diocesan seminary. During the 16th century it was one of the most flourishing European settlements in the East; its walls described a circuit of 6 m., and enclosed a population of 150,000 Christians and 50,000 Mohammedans. About that time it was ravaged by a pestilence, and this misfortune, combined with various political complications, led to its decline. St. Francis Xavier is buried there.—NEW GOA, PANJIM, or PANGAUM, situated on the same island, 5 m. nearer to the sea than the old town, on a fine bay S. of a headland called Algoada point, with 2 lighthouses, is a fortified place, and the present Portuguese capital in the East, but is ill built and declining; pop. about 20,000. It is almost deserted by the mother country, and is visited by not more than 2 or 3 Portuguese ships in a year. It has a small trade with China, with Macao and the British ports, and

with various settlements along the coast. Its harbor is scarcely inferior to that of Bombay. There are no drives, promenades, or places of amusement, and little sociality. The inhabitants are impoverished, many of the highest families supporting themselves by working lace, &c. Crime is rife among the lower classes; the police is inefficient, and no attention is paid to cleanliness. The seat of government was removed hither in 1758.—Goa was seized by Albuquerque, recovered by its native sovereign, and again taken by the Portuguese general in 1510, after a bloody assault. He improved its defences, and made it the capital of all his conquests; and except during the period between 1807 and 1815, when it was held by the British, it has ever since remained in the possession of Portugal.

GOALPARA, or N. E. Rungpook, a district of Bengal, British India, bounded N. by the native state of Bootan, E. by the district of Camroop, S. by Mymensing and the territory of the Garrow tribes, and W. by Rungpook and Cooch Bahar; area, 8,506 sq. m.; pop. 400,000. It produces cotton, tobacco, sugar, and mustard. Though belonging properly to Bengal, of which it formed a part on the acquisition of that territory by the British in 1765, it is often regarded as a district of Assam, with which country it is naturally connected by similarity of climate, soil, &c.

GOASCORAN, a town in the S. part of Honduras, Central America, on a river of the same name; pop. 500. The town is insignificant, but the river has a great importance from the facilities which it affords for interoceanic communication by means of railways between the Atlantic and Pacific oceans. It rises about 20 m. S. of the city of Comayagua, the capital of Honduras, and flows due S. into the bay of Fonseca, opposite the port and town of La Union, its total length being 80 m. Its upper waters communicate with those of the river Humuya, which flows due N. into the bay of Honduras. In conjunction with the plain of Comayagua, the valleys of these two rivers form a great transverse valley, extending from sea to sea, through which the Spaniards contemplated building a canal, and through which an English and American company is now engaged in constructing a railway. The river is navigable for small boats, but only for short distances.

GOAT (*capra*, Linn.), a well known hollow-horned ruminant, of the sub-family *ovina*, which contains the goats and sheep. The genus is characterized by a convex forehead, nose for the most part straight in its upper outline, and the absence of lachrymal sinuses and secreting glands between the hoofs; the horns, present in both sexes, but larger and more angular in the males, are of a dull yellowish brown color, compressed and nodose, with a sharp edge behind and before, curving backward, but not completing a circle, and the tips never coming forward; their curve, unlike those of the sheep, forms part of a circle whose diameter is much

longer than the head; their osseous nucleus is porous or cellular, communicating with the frontal sinuses; the chin is bearded, the tail very short and naked below, the hoofs as high on the inner as on the outer side, and the mammae, 2 in number, forming an udder; the nose is covered with hair except a narrow naked space between the nostrils; the limbs are strong, with a callosity on the carpus. The dental formula is: incisors $\frac{2}{2}$; canines none; molars $\frac{2}{2}$; in all 32 teeth. The hair is never very coarse, and sometimes remarkably fine, with a woolly down underneath. The time of gestation is 5 months, and the number of young generally two; the female is capable of propagating at 7 months, and the male at a year old; the age of the goat may be extended to 15 years, though they are generally old at 6. The males emit a powerful odor, especially during the love season; they are libidinous and pugnacious, rising on their hind legs and butting downward with the whole weight of the body. Fearless, capricious, gregarious, and active, they are ever in motion, ascending the most giddy heights, and springing with great precision from rock to rock where there seems hardly a possibility of their obtaining a foothold; their sight and smell are acute, their structure robust, and their habits vigilant. From the nature of their mountainous retreats, the hunting of the wild species is both difficult and dangerous; when hard pressed they have been known to turn upon the hunter, and thrust him and themselves over fearful precipices. The goats include the ibex of Europe, Asia, and Africa (see IBEX); the wild *agagrus*, the Jemlah goat or the jharal; there is no goat indigenous to America, the so called Rocky mountain goat being in reality an antelope.—The common wild goat (*C. agagrus*, Pallas) inhabits the mountains of the Caucasus, Asia Minor, and Persia, and according to some the European Alps. It is higher on the legs than the domestic goat, and the body is more slender; the limbs and neck are robust, and the horns are large in proportion to the size of the animal. The general color is grayish brown above, with a dark dorsal line and blackish tail; the colors are paler in the female, and the lower parts in this sex are sometimes whitish. They have the habits of the domestic goat, and are one of the many original stocks of the latter. Another wild species is the Jemlah goat (*C. Jemlahica*, H. Smith.) with depressed, knobby, wrinkled horns, a solid, heavy skull, and robust limbs; the hair on the neck and back is abundant, long, and loose, and on the sides of the head very coarse; the tail is very short; the color is a dirty whitish fawn, with a few brown shades and a dark stripe along the back. It inhabits the district of Jemlah, in the elevated mountain chain of central Asia. The *C. corsus* and *C. imberbis* (Blainville) are believed to be domesticated varieties of this species. The jharal of Hodgson is by Gray referred to the same species as the last, forming the genus *hemitragus* (Hodg.); they have 4 mammae.—The domestic

goat (*C. hircus*, Linn.) resembles the *C. agagrus* more than any other wild species, and was probably derived from this mixed with the various species of ibex, and if left in its original independence, without the care of man, will approximate more or less to the *agagrus* and the ibex; on the usually recognized principle that the varieties most resembling the wild goats are nearest their original types, we find some of the breeds very far removed from and others very near to the above described species. The common goat of the mountainous countries of Europe much resembles the *agagrus*, and has in some places become so wild as to be difficult of approach, and to be obtained only by the hunter's rifle; the ears are small and upright; the size of the body is smaller, the hair coarser, the horns more vertical and turning outward, and the colors more varied with black and white. As the variety becomes removed from the wild original, the hair becomes finer, the ears large and pendulous, the horns either absent or multiplied, and the stature and proportions modified. The Persian goat resembles a small *agagrus*; the hair is long and coarse. The Welsh breed is large, generally white, with long fine hair, and with vertical horns about 8 feet long. There are small hornless breeds of goats in South America, the West Indies, and the Pacific islands, supposed to have originated from Africa. The Angora has long soft hair, mostly white, long ears, upright yellowish horns, and a sheep-like look. The famous Cashmere and Thibet breeds have long, straight, silky hair, large pendent ears, and slender legs; for an account of the uses of the hair of these goats, see the article CASHMERE. The Nepal goat is of a high and slender figure, of a black color, with an arched form of nose from convexity of the nasal bones, and long hanging ears of a whitish color. The goat of upper Egypt is of a brownish color and high stature, with long shaggy hair, arched nose, ample pendent ears, and the upper jaw so much shorter than the under that the lower incisors and chin are exposed as in the pug dogs. The varieties of the goat, as of other domesticated animals, from circumstances of climate, food, and the care and caprice of man, have become almost endless. This useful animal in primeval ages formed a great portion of the flocks of southern Europe, Asia, and northern Africa; figures of a very large race are found on the early Egyptian monuments; the goat preceded the sheep in northern and western Europe, predominating while the country was covered with forests. Goat skins were probably among the first materials used for clothing among the northern and Scandinavian nations. The milk of the goat is used for making cheese and for domestic purposes in mountainous regions, and is prescribed as a medicine in debilitated constitutions and pulmonary diseases. In the malarious regions of Asia and the East, cow's milk is regarded as a predisposing cause of bilious fevers and diseases of the liver, and goat's milk is therefore sub-

stituted; this custom might perhaps be imitated with advantage in malarious districts of the United States, Mexico, and the Pacific coast. The flesh of the kid is esteemed as food; from the skin are made fine gloves, various garments, and the real Morocco leather; from the hair of one variety are manufactured the costly fabrics of Cashmere. Many persons keep goats as pets, as they are lively and docile; in the public gardens of Europe they are used to draw children's carriages, obeying the rein and the voice like ponies.—The Rocky mountain goat is referred to the genus *capra* by Desmoulins, Harlan, Sundevall, Richardson, Bachman, and Van der Hoeven; but recent examinations go to show that in all its essential features and affinities it is an antelope, and belongs to the genus *aplocerus* (H. Smith). It resembles the goat and merino sheep in its figure and size; the horns are small, conical, smooth, nearly erect, and jet black. The outer hair is long, straight, and white, as fine and soft as that of the Cashmere goat; the chin is bearded; the external fleece hangs down all over the body and upper part of the legs; the under hairs are soft and silky like wool. It inhabits the highest and most inaccessible peaks of the Rocky mountains between the parallels of 40° and 65° N., and is most abundant in Washington territory; it is very difficult to procure; the mountain sheep (*ovis montana*, Cuv.), or big-horn, has been often mistaken for it by travellers; its flesh is hard and dry.—The goats are rarely found fossil, and belong nearly to the same epoch of creation as man, forming probably the first step by their domestication in his progress toward civilization; the dog, man's earliest companion, was a protector even in savage life, but the goat would lead him from the pursuits of hunting to the more peaceful occupation of the shepherd, with the consequent improvement in the arts of clothing and building. The goat (*capricorn*) was one of the signs of the ancient zodiac; the mythological Pan, the god of shepherds and the supreme power over nature, was represented with the horns and legs of a goat; the *agis*, or shield of Jupiter, was covered with the skin of a goat; this animal was sacred to several ancient divinities, and sacrificed at their altars, and even under the Jewish dispensation was emblematical of atonement. The goat may well be called the poor man's cow, supplying him at small expense with milk, cheese, meat, and materials for clothes. In the United States, the goat has been until recently considered one of the least valuable of domesticated animals. The large Sindh goat, from the mouth of the Indus, characterized by pendent ears 22 inches long, used in Asia for the table and the dairy; the Malta goat, which gives about a gallon of milk daily, and various Swiss breeds, were introduced some years ago, but were gradually neglected, so that it is now doubtful if their milk is made into cheese in any section; the hair was too coarse for manufacturing purposes, and their flesh inferior to

veal and mutton; in fact, farmers generally did not consider them worthy of notice as stock. By selecting the best varieties, and paying attention to climate, food, and other circumstances within his control, man has succeeded in transplanting and perpetuating the most valuable breeds in countries far removed from the original. The country of wool-bearing goats *par excellence* is the mountainous region of Thibet, extending thence northward to the arctic regions, eastward through Chinese Tartary, and westward through Russia to the confines of Europe. Dr. James B. Davis, of Columbia, S. C., in 1849 introduced into that state 7 females and 2 males of the pure Cashmere breed; in 1853 the flock of pure breed had increased only to 30, from the accidental circumstance of the young having been chiefly males; they had kids every spring, usually one at a birth; the half and quarter breeds with the common goat were much more numerous. He found them good for the table, easily fattened, with long fine hair equal in all respects to the imported stock, with a much heavier fleece; and the mixed breeds were a great improvement on the common goat. The pure males were readily sold at \$100 each, and the mixed breeds eagerly purchased by persons desirous of improving the common varieties. From the experiments thus far prosecuted it appears that the fleeces raised in this country closely approximate in fineness to the best Asiatic specimens, and the cross with the common goat shows no deterioration in the hair; the precious wool at the base of the hair in winter, averaging only 3 ounces to each goat in Cashmere, from which the costly shawls are made, deteriorates neither in quantity nor quality if proper regard be paid to the temperature of the locality. The value of the Cashmere fabrics is not so much in their fineness as in their durability, and their cost is very greatly increased by the difficulties, expenses, and taxes incurred in their transit from Thibet over land to eastern Europe. The demand for woollen fabrics of fine texture will always make it profitable to pursue this branch of industry, which is well suited to many parts of our country. The history of Dr. Davis's experiments is given in the "Agricultural Reports of the Patent Office" for the years 1853 and 1855; and in the same work for 1857 will be found a report on these Asiatic goats by Dr. Bachman, giving the results of the experiment under several heads. They are very hardy, suffering neither from heat nor cold, this hardness being imparted to half-blood intermixtures with the common goat; they have been free from disease during the 8 years since their introduction, are good breeders, take care of their young, and furnish an abundant supply of milk; the proportion of male offspring seems to increase with the age of the buck. Goats sometimes gnaw fruit trees, but prefer weeds, briars, and leaves to grass, and have been found beneficial to grass lands in summer by feeding on such growths; they are fond of the leaves

of young pines and cedars, and seem to require something of the kind to preserve them in health. The flavor of the flesh of the half-breeds is superior to that of lamb or mutton, somewhat resembling that of venison. They are not liable to be killed by dogs like sheep, as a herd of goats will form a ring and defend the kids and ewes. The fleece of the bucks was found to weigh, cut in April, from 5 to 7 lbs., and that of the ewes from 4 to 5 lbs.; that of the kids is fine enough for the finest shawls, and that of the old ewes and yearling bucks will make valuable cloth. The report says: "There is a large class of fabrics for which these fleeces are peculiarly adapted, namely, camlet and worsted goods and ladies' fabrics, as challies, mousseline de laine, gentlemen's clothing for summer, hosiery, &c." These are strong, handsome, durable, and of a lustre far superior to articles made from the wool of the alpaca and sheep; they also receive and retain the most brilliant coloring. The experience of Dr. Davis and others shows a remarkable tendency of the cross between the Asiatic male and the common female goat to assume the higher and more valuable characters of the former, becoming finer fleeced and more prolific. Many parts of the United States are suited to this Asiatic goat and its crosses; they need but little water, and would require to be fed in unfavorable localities only in winter; the districts best adapted to them are the sides of the Rocky and Alleghany mountains, the hilly and almost uncultivated region of the Carolinas and Georgia, the western country from Nebraska to western Texas and New Mexico, the mountain tracts of Virginia, North Carolina, Kentucky, and Tennessee, and the worn-out plantations and poor pine lands of the southern states; a single shepherd, with his trained dog, could guard a flock of several thousands against wolves, curs, and other carnivorous enemies. It has been ascertained that Cashmere goats brought from their mountains to the warmer plains of British India, where the mean annual temperature is 65°, lose the fine soft wool at the base of the long hair in the course of a single year; it may be stated as an important fact that the best fleeces require the mountainous districts of a warm country, and not a certain temperature without regard to elevation; the altitude as well as the latitude of a region should be considered in locating them. By attention to the breed, and selecting the finest and accidentally improved individuals, new and superior varieties may be produced, surpassing even the Cashmere originals. In all probability the Rocky mountain goat-antelope might be easily domesticated, and prove still another source of profit to the agriculturist and manufacturer.

GOATSUCKER, a nocturnal fassirostral bird, of the order *passeres* or *insessores*, and the family *caprimulgida*. The family is characterized by a short, very broad, depressed bill, with an immense gape extending beneath the eyes, and

rendered larger by numerous bristles for arresting their insect prey; the eyes are very large, and easily puzzled by the full light of day; the tarsi are short and weak, the toes long, the hind toe closely united to the base of the inner; the plumage is soft, enabling them to fly without noise. In the sombre colors and texture of the feathers, in the large head and eyes and nocturnal habits, they resemble the owls, but zoologically they come nearest to the swallow family. The name goatsucker is derived from the Latinized Greek appellative *caprimulgus*, which originated in the idea that they suck the mammae of goats, natural enough when the enormous size of the gape is considered; the French call these birds *engoulevents*, or wind swallows, and *crapauds volants*, or flying toads, probably on account of the great capacity of the mouth. Like the owls, they hide themselves by day, coming out toward sunset, and pursuing insects on the wing with great rapidity during the twilight; they make no nests, but deposit their eggs on the bare ground or in slight concavities; they are found in all parts of the world, but most abundantly in South America. There are 3 subfamilies: *steatornis*, or oil-birds, found in the West and East Indies, Australia, Africa, and South America; *caprimulgina*, alone represented in the United States; and *podagerina*, in Africa and South America. In the first family the genus *steatornis* (Humboldt) becomes so plump on the rich palm fruits of Guadeloupe and Trinidad in the breeding season that their fat is compared to that of olive oil, and as such is permitted to be used during Lent by the Catholic natives. Some species of the genus *nyctibius* (Vieill.) are as large as a short-eared owl. Among the *caprimulgina* are included the European goatsucker, the North American chuck-will's widow, whippoorwill, and night hawk, and the South American scissors-tailed goatsucker. The European species (*caprimulgus Europæus*, Linn.) is as large as a thrush, of a gray brown color, undulated and spotted with blackish brown, with a band of white from the bill to the nape; it nestles in the furze, and lays 2 eggs. From the nature of its food and its method of taking it, and its manner of flying, it is often called the square-tailed swallow; it is rather a solitary bird, feeds on nocturnal insects like moths and beetles, which are retained as it flies with open mouth by a viscid saliva, and perches longitudinally on a branch; it migrates during winter into southern Europe and northern Africa. The chuck-will's widow (*C. Carolinensis*, Briss.; *antrostomus*, Gould) is the largest of the North American species, being about 18 inches long, with an extent of wings of 26 inches; it has very strong bristles at the base of the bill, each with lateral filaments; the wings are long, and the tail slightly rounded; the prevailing color is pale rufous, the top of the head reddish brown with longitudinal black streaks, the last $\frac{1}{4}$ of the tail feathers (except the 4 central) rufous white, with the outer webs of all mottled; the female

has no white patch on the tail; it is found in the southern Atlantic and gulf states. The popular name of the bird is derived from the sounds which it utters very clearly and strongly 6 or 7 times in quick succession in a melancholy tone; they are seldom heard in cloudy weather, and never, according to Audubon, when it rains. The flight is rapid, graceful, and elevated. It makes its appearance from the south in the gulf states about the middle of March; the male courts the female with great pomposity; no nest is made, but the eggs are laid among the dead leaves; if the eggs be disturbed, the birds remove them in their mouths (according to Audubon, who witnessed the fact), and place them in another locality; they probably remove the young in the same manner. They manifest a great antipathy to all kinds of snakes, and, though they cannot harm them, attempt to frighten them away by opening their immense mouths and making a strong hissing noise. They leave the United States about the middle of August. The whippoorwill (*C. vociferus*, Wils.) and the night hawk (*chordeiles Virginianus*, Briss.) will be described under their proper titles. The scissors-tailed species (*C. furcifer*, Vieill.), of Paraguay, is remarkable for the length of the outer feathers of the tail, gradually diminishing to the tip. Among the *podagerina* is the Leona goatsucker (*macrodipteryx longipennis*, Shaw), a native of Africa, having the innermost quill of the wings extremely prolonged and deficient in webs except at the end, and longer than the bird itself. The genus *podager* (Wagl.) has long wings and short even tail, and short and feathered tarsi; it is found in the warmer parts of South America, frequenting fields and moist places, usually in pairs, but occasionally in large flocks, chasing insects in the full light of day; it lays 2 eggs on the bare ground. Most of the goatsuckers have the inner edge of the middle claw pectinated, like a comb, for the purpose of cleansing the bristles of the bill from remains of insects and particles of dirt.

GÖBEL, TRAUGOTT FRIEDEMANN, a German traveller and writer on chemistry, born in Thüringia in 1794, died May 27, 1851. In 1828 he was appointed professor of chemistry at Dorpat. In company with Claus and Bergmann he travelled in southern Russia in 1834, and embodied the results of his scientific investigations in his *Reise in die Steppen des südlichen Russlands* (2 vols., Dorpat, 1838). He wrote many manuals of chemistry, the principal of which is his *Grundlehren der Pharmacie* (4 vols., Erlangen, 1843-'4). His most celebrated work is the *Pharmaceutische Waarenkunde*, which was completed by Kunze.

GOBELINS, ROYAL MANUFACTORY OF THE, an establishment in Paris belonging to the French government, devoted to the production of tapestry and carpets. It is situated in the faubourg St. Marcel upon the Bièvre, being No. 270 rue Mouffard. It derives its name from Jehan Gobeelen, a Flemish dyer, who removed

hither in the middle of the 15th century, and almost monopolized for years the dyeing business of Paris. He erected a quaint unsightly building, which was known as "Gobelin's folly," and which afterward, passing into other hands, came to be used for a manufactory of tapestry, first by the brothers Cannaye, and about 1665 by the Dutchman Geuck and his skilful workman, Jean Lioudson, the latter first manufacturing the fabric there upon the *haute lisse*, or high loom. In 1667 Louis XIV., adopting the suggestion of Colbert, organized a distinct department for the production of the furniture and decorations of the royal palaces, calling it the *manufacture royale des meubles de la couronne*. The hotel of the Gobelins had a few years previously been secured with a view of continuing in it the tapestry manufactory. The direction was given to Lebrun, who painted his famous battles of Alexander the Great as patterns for this manufactory. The celebrated engraver Sebastian Leclerc was furnished with apartments and continued in the service of the establishment for 40 years to the time of his death. Artists were engaged by liberal offers to remove from the famous manufactory at Brussels, among whom was the elder Lefèvre and others distinguished by their copies of the cartoons of Raphael and Giulio Romano. The highest talent was directed to the production of original picture designs, and pupils were instructed as in a school of art. Works were also executed in marble, as tables inlaid with colored stones, and sculptures, of which some pieces are among the finest productions in this department of the fine arts. Though the works were up to this time open to private orders, their prosperity was chiefly dependent upon the patronage of the government; and when this was in great part withdrawn in the pecuniary embarrassments of the crown after the year 1694, the operations were greatly checked, and for a time during the reign of Louis XV. the establishment was closed. In 1791 a new system was introduced, and the operations were restricted to the production of tapestry. The workmen, instead of executing this as before by contract from the materials furnished them, were now employed by the year; and their attention was more particularly directed to the quality than to the quantity of the work they accomplished. The weaving of pictures in colored wool demanded as high manipulative talent as painting upon canvas. Six large rooms are devoted to the *hautes lisses*, or high looms, upon which the tapestries are suspended as the work goes on. The warp hangs from a horizontal cylinder, and as every yard or thereabout in length is completed, it is wound upon another cylinder in the lower part of the frame. The principal features of the design being traced with white chalk by the artist upon the stretched thread of the warp, he marks, with the aid of tracings from the picture, which he attaches to the warp, the exact positions of the light and dark shades. Then with the pattern conveniently

placed for reference, the artist stations himself against the back of the tapestry, and, with his worsteds and silks at hand, begins to work in the different colors. The vertical threads of the warp are divided by a heddle or cross stick which keeps half of them in advance of the rest; but those behind can be brought forward whenever required by means of small cords (*lisses*), one of which is attached to each warp thread. The left hand is introduced between the two sets of threads, taking up as many as need be, and through these the wooden needle with its worsted is next passed from left to right. The thread when stretched is piled with the point of the needle, and is then passed back in the contrary direction through the space opened by shifting the position of the front and back threads. By ingeniously combining the woofs, the colors are made to blend perfectly, and effects are obtained like those of painting. The work is so slowly executed that an artist is not expected to average in a year a production of more than about a square metre, or a little more than 39 inches square, the value of which may be about 8,000 francs.—In 1826 the manufactory of carpets, called *la savonnerie*, from an old soap factory in which the making of carpets had been carried on from the year 1615, was connected with the tapestry establishment. The operations here are conducted upon the high loom, of larger size than those in the tapestry department, and the workman is placed in front. The worsted employed is composed of a number of shades, sometimes as many as 9 or 10, combined so as to imitate exactly the model. The carpets are remarkable for smoothness and evenness of texture and their strength and fineness, excelling even the Persian in these respects. The colors and designs also are perfect. Some of them require from 5 to 10 years for their completion, and cost 60,000 to 150,000 francs. None are sold. The largest ever made was manufactured for the gallery of the Louvre. It consists of 72 pieces, the total length being more than 1,800 feet.—The establishment is open to the public every Wednesday and Saturday, and every second year an exhibition is had at the Louvre of its productions, together with those of Beauvais and Sévres. The most celebrated piece executed at this establishment is a picture, completed about the year 1844, of the "Massacre of the Mamelukes," after the celebrated work of Horace Vernet. It is kept in the rooms as the most perfect production for the study of the artists employed. In 1851 it was sent to the great exhibition at London. A number of exquisite pieces of less importance were sent to the New York exhibition in 1853, among which the "Subject taken from the Chase and Still Life" was referred to as excelling in the softness, delicacy, and brilliancy with which all the minute traits of both animal and vegetable life are rendered in these colored woofs. In the "Report" of this exhibition, p. 186, is a full description of the Gobelin establishment.

GOBERT, NAPOLEON, baron, a French phi-

lanthropist, born in 1807, died in Cairo, Egypt, in 1838. He was the son of a general killed at Baylen, and the godson of Napoleon. He entered the army, in which he obtained little distinction. By his will the French academy and the academy of inscriptions were made his residuary legatees, on condition that the former should award $\frac{2}{3}$ of the income of its share of the legacy as a prize to the author of the most eloquent work on French history that had appeared during the year preceding the distribution, and $\frac{1}{3}$ to the one next in merit; and that the academy of inscriptions should award similar prizes to the authors of the first and second most learned and profound works on the history of France; this income to be paid annually to the recipients until better works of the same kind should appear. The heirs unsuccessfully contested the bequest, but the academies compounded with them, and secured an income of 10,000 francs each, which has since 1840 been disposed of in accordance with the provisions of the will.

GOBI, or COBI (Mongol, an elevated plain), also called SHAMO by the Chinese, an immense tract of country in central Asia, extending from a spur of the Altai chain striking out near the E. extremity of the Siberian government of Irkootsk to the point of intersection of the 3 vast ridges of the Altai, the Kuen-Lun, and the Himalaya, and occupying the table-lands between the first two of these ranges. It has a length from N. E. to S. W. of 1,800 m., and a width varying from 200 to 500 m., with an area of perhaps 600,000 sq. m. This immense tract is divided in its W. part a little N. of the middle by the Thian-Shan or Celestial mountains. It is generally also divided into the E. and W. desert. The line of this division is where the desert leaves the E. boundary of the Chinese province of Kan-su. Of the W. part, that which is included in the province of Kan-su is the least sterile of the whole desert, while that which lies W. of the province enclosed between the mountains is the most desolate region conceivable. Its surface consists of a fine loose sand, which is drifted about by the winds in waves like water. The water-shed between the Celestial mountains and Kuen-Lun is drained by the Yarkand and its confluent Kaahgar, flowing eastward into Lake Lop, just within the province of Kan-su. This lake has no outlet. Such lakes are numerous throughout the desert, especially in W. Gobi. The eastern part of Gobi is better known than the western, and is not quite so inhospitable. The Chinese term Shamo is applied especially to this part of the desert. In physical conformation it is a vast valley or basin of uneven surface, extending between the broken chain formed by the meeting of the Kuen-Lun and the above mentioned spur of the Altai on the S., and the Altai chain itself on the N. Like W. Gobi, it is a vast sea of sand, but this is coarser, so that it is not so much moved by the winds. It is drained toward the E. into the sea of Okhotsk by the confluent sources of the Amoor, and to the N. into Lake Baikal be-

yond the Altai by the Selenga and Orkhov. The soil of the entire desert is impregnated with salt, especially in the W., and the waters are brackish. In E. Gobi, in the mountainous districts which skirt the valley, are some fertile plains, where agriculture is a little attended to by the inhabitants, and yields a precarious subsistence. Pasturage is more commonly the occupation of the Mongolian tribes, who lead a nomadic life in these mountain fringes of E. Gobi. In W. Gobi also, around the numerous salt lakes, and on the banks of its steppe rivers, the Turkish Tartars pitch their tents and raise their cattle. The climate of the desert is intensely cold, and winter lasts 9 months. It frequently freezes and snows in July and August, although Gobi lies between lat. 35° and 50° N. The part of W. Gobi included in Kan-su is considerably settled, and has some important towns, as Hami, Ngansi, and Su, the last situated near the W. extremity of the great wall of China, which may be regarded as forming the boundary between the fertile lands and the desert.

GOD SAVE THE KING, a popular melody, commonly regarded as the national anthem of Great Britain. It has been ascribed to John Bull, chamber musician to James I., to Anthony Young, a London organist, and to Handel, and is even supposed to have been sung by the peasantry of southern France for centuries before it was known in England. Dr. Burney maintains that it was composed for the Roman Catholic chapel of James II.. The author was probably Henry Carey, a natural son of the earl of Halifax; and the tradition that Christopher Smith, Handel's clerk, was employed to correct the words as well as the music, gave rise to the assertion that it was the production of the latter composer, who was also accused of having appropriated the melody and rhythm from the old French composer, J. B. Lulli. "God save the King" was first published in the "Gentleman's Magazine" in 1745, and upon the landing of the young pretender in the same year became a rallying song for the adherents of the house of Hanover. About the same time it was introduced upon the stage by Dr. Arne, and has since retained its rhythmical form unaltered, although the melody and harmony have been much improved. The words are also essentially the same, the only changes being those rendered necessary by the introduction of new names at the accession of successive sovereigns. Under Victoria it is called "God save the Queen."

GODAVERY, a large river of British India, rising in the W. Ghats, in the district of Ahmednuggur, lat. 19° 58' N., long. 78° 30' E., and, after a S. E. course of 398 m. across the peninsula, flowing into the bay of Bengal by two principal channels. The delta commences at Pechakalunka, in lat. 16° 57' N., long. 81° 49' E., and contains an area of 500 sq. m. The banks of the river on each side are marked by ridges a few feet high, formed by deposits during the inundation. There are few or no obstructions to navigation, but the stream has been

little used as a channel of commerce, until within a few years measures have been taken to place steam vessels on it. In 1846 the East India company began the construction of an annicut or dam, 12,600 feet long, which secures during the dry season an unfailing supply of water in the delta of the river for irrigation and navigation. Boats are enabled to pass it at this time by means of a series of locks, but in the rainy season the waters are high enough to enable vessels to sail over the dam. The principal affluents of the Godavery are the Paira, Doodna, Manjara, Manair, and Wain Gunga.

GODERICH, VISCOUNT. See **RIPON, EARL OF.**
GODFATHERS AND GODMOTHERS, persons who become sponsors for a child at its baptism, promising in its name that it shall lead a Christian life, and binding themselves to watch over its religious education. The custom of having sponsors probably originated in the infancy of the church, from the desire to prevent children from being brought up in idolatry in case their natural parents should die before they came to years of discretion. In the church of England the number of godparents is limited to 3; in the Roman Catholic church to 2. In England it was an old custom for godfathers and godmothers, every time their godchildren asked their blessing, to give them a cake, which was called a gods-kichell (or gods-cake). The usage for the sponsors to make presents to the child at the christening is of considerable antiquity. The customary gifts were gilt spoons, on the handles of which were graven images of the apostles. The rich gave a whole set of 12, but poor children often had no more than one. In Beaumont and Fletcher's "Noble Gentleman" Longueville is made to say:

I'll be a gossp, Beaufort;

I have an odd apostle-spoon.

Stow's Chronicle (1631) mentions a former custom of sponsors giving "christening shirts with little hands and cuffs, wrought either with silke or blew threed."

GODFREY, THOMAS, an American mathematician and mechanician, the inventor of "Halley's quadrant," born in Philadelphia, died in Dec. 1749. He had but a common education, and followed the business of a glazier in his native city; but accidentally meeting with a mathematical treatise, he was delighted with the study, and pursued it with such ardor and industry that he mastered all the books on the subject that he could obtain, and instructed himself in Latin in order to read mathematical works in that language. He borrowed a copy of Newton's *Principia* from James Logan, secretary of the commonwealth, and in 1730 communicated to him an improvement that he had made in the quadrant. In 1732 Logan gave an account of the invention to Dr. Edmund Halley of England in a letter, and Godfrey also prepared a description of it addressed to the royal society of London, but did not send it, awaiting the effect of the letter to Halley. No answer

was received after an interval of a year and a half, and then the invention of Godfrey was laid before the royal society by the botanist Peter Collinson. Meantime, in 1731, Mr. Hadley had presented a paper containing a full description of an improvement of the quadrant similar to that of Godfrey. The rival claims were investigated by the royal society, and it was decided that they were both entitled to the honor of the invention, and a reward of £200 was bestowed on Godfrey, in household furniture instead of money, on account of his intemperate habits. Different statements are made of the way in which the invention of Godfrey might have become known to Hadley. Dr. Franklin lived in the same house with Godfrey, and says that, like most great mathematicians whom he had met, he was not a pleasant companion, since he expected universal precision in every thing said, and was perpetually denying or distinguishing on trifles, to the disturbance of all conversation.

GODIVA. See **COVENTRY.**

GODMAN, JOHN D., an American physician and naturalist, born in Annapolis, Md., Dec. 20, 1794, died in Germantown, Penn., April 17, 1880. Left an orphan and without property, he was apprenticed after a short schooling to a printer in Baltimore; but in 1814 he abandoned an employment which had never pleased him, enlisted in the navy, and was present at the defence of Fort McHenry. In April, 1815, he left the service with the purpose of following the medical profession, and began his studies under Dr. Luckey in Elizabethtown, whence he soon after removed to Baltimore and placed himself under Dr. Hall, and afterward under Drs. Wright and Davidge. His progress was so rapid that before he was graduated he made a reputation by a few lectures on anatomy delivered in place of Dr. Davidge. After obtaining his degree, in Feb. 1818, he practised successively in New Holland, Penn., in Anne Arundel co., Md., in Baltimore, and in Philadelphia. In 1821 he was appointed professor in the medical college of Ohio, at Cincinnati, but he held this post only a few months, and in 1822 returned to Philadelphia, to devote himself to scientific pursuits. A private class in anatomy which he organized at this time was largely attended, but his close application and the bad air of the dissecting room seriously impaired his health. In 1826 he accepted the chair of anatomy in the Rutgers medical school, New York, but before finishing his second course of lectures he was obliged to undertake a voyage to the West Indies, on his return from which he settled in Germantown. In spite of early disadvantages Dr. Godman was a good scholar, a linguist, and an attractive writer. He prepared the articles on zoology for the "Encyclopædia Americana" as far as the end of the letter C, contributed to the "American Quarterly Review" and various scientific periodicals, and edited the "Western Quarterly Reporter of Medical Science" in Cincinnati and the Philadelphia "Journal of the Medical

Sciences." His principal work is his "American Natural History" (3 vols. 8vo., Philadelphia, 1822-'8), beside which he published an "Account of some Irregularities of Structure and Morbid Anatomy;" "Bell's Anatomy," with notes; "Anatomical Investigations;" a translation of Levasseur's "Account of Lafayette's Progress through the United States;" "Rambles of a Naturalist;" numerous addresses, &c.

GODOLPHIN, SIDNEY, earl of, an English statesman, born in Cornwall about 1640, died Sept. 5, 1712. He began his political career under Charles II. as one of the grooms of the bedchamber, became one of the lords of the treasury in 1679, voted for the exclusion of the duke of York from the throne in 1680, was placed at the head of the treasury in 1684, and after the accession of James II. was retained in office as chamberlain to the queen, and became one of the chief royal advisers. He took office under William III., having become an almost indispensable part of the machinery of state, was placed at the head of the treasury, and on the accession of Queen Anne in 1702 was created lord high treasurer, being the first person who had held that office since the restoration. After the revolution he was led by Marlborough to doubt the stability of the new government, and he served it for 6 years while at the same time sending professions of attachment and promises of service to James. In 1706 he was created Viscount Rialton and earl of Godolphin, attached himself to the whig party, and the final result of his struggle with Harley for the premiership was his sudden and rude dismissal from office in 1710. Godolphin was a veteran courtier, and the most prudent and experienced of the financiers of his time. "Every government, therefore," says Macaulay, "found him a useful servant; and there was nothing in his opinions or in his character to prevent him from serving any government." He was one of the keenest gamblers and horse-racers of his time.

GODOY, MANUEL DE, a Spanish statesman, the favorite of Charles IV., born in Badajoz, May 12, 1767, died in Paris, Oct. 4, 1851. With a handsome figure and winning manners, he went to Madrid to seek his fortune. He obtained the notice first of the ladies of the court and then of the queen, whose favorite he became, and of the king, and his talent for intrigue gained him rapid advancement, till he had unrivalled ascendancy over Charles IV. With neither military nor administrative capacity to merit such distinctions, he was created duke of Alondia, generalissimo of the land forces, grand admiral of Spain and of the Indies, secretary of state, prime minister to succeed Aranda in 1792, chevalier of the golden fleece, and a grandee of Spain of the first class. When Louis XVI. of France was brought to trial by the convention, Godoy declared war against France, but by treaties concluded in 1795 and 1796 he separated Spain from England, and formed an alliance offensive and defensive with France. For this service the king gave him the title of "prince of the

peace." Maria Theresa de Bourbon, niece of the king, was constrained in 1797 to marry him. It is alleged that he was already secretly married to Josephine Tudo, the daughter of a military officer. Obligated in 1798 to resign his power for a time, while the English were blockading the Spanish ports, he resumed it again in 1801, when he signed the treaty of Badajoz, which divided Portugal between Napoleon and Charles IV., and which by a secret article gave to himself over \$3,000,000. His regular annual revenue at this time was not less than \$1,000,000, and he possessed unlimited power in the government. He however incurred the hatred of the nation, which saw its naval power annihilated by the battle of Trafalgar, and its commerce stopped by the blockade of its ports; and soon a strong party was formed against him under the patronage of the prince of Asturias, afterward Ferdinand VII. When Napoleon determined upon the dethronement of the Bourbons of Spain, and at the same time a criminal suit instigated by the prince of Asturias was pending against Godoy, the latter advised the royal family to take refuge in America. This project was not matured when an insurrection broke out against Godoy, who was seized by the populace in his hotel, and his life having been with difficulty saved, he was held prisoner to await the course of justice. Napoleon however, who knew his great influence over Charles IV., wished to avail himself of it to secure the renunciation of the crown of Spain by that monarch, and therefore obtained his freedom, and invited him to the conferences of Bayonne. Godoy drew up the act of abdication signed by the king, whom he then accompanied in his exile to Rome; and his immense possessions in Spain were confiscated. The partiality of the king for him remained after the ruin of both of them, and the ex-monarch often said to him regretfully: "I am the cause of all your misfortunes." Godoy lived in Paris after the death of Charles IV., and received a pension from Louis Philippe. In 1842 he was reinstated in his dignities in Spain, but he continued to reside in France. While in power in Spain he sought to effect some reforms, and opposed the influence of the clergy and the inquisition.

GODWIN, earl of Wessex, a Saxon noble, born about the end of the 10th century, died April 7, 1054. He was a cow-herd, but having ingratiated himself with Ulfr, the brother-in-law of King Canute, he received in marriage the daughter of that chieftain, and became the most powerful nobleman in England. In the interest of Harold Harefoot he procured the murder of Prince Alfred; but he was pardoned both by Hardicanute and Edward the Confessor, Alfred's brothers, and exerted himself to secure the crown for the latter. He afterward rebelled against Edward, and was obliged to flee the kingdom, but returning with a body of troops, forced his way back to favor. He was the father of Harold, the last Saxon king.

GODWIN, GEORGE, an English architect and author, born in Brompton, Middlesex, Jan. 28, 1815. He was instrumental in founding the London art union in 1836-'7, of which for the last 20 years he has been chief honorary secretary, and to the "Art Union Magazine," now the "Art Journal," he became a constant contributor after its establishment in 1839. In 1844, having previously published "The Churches of London," he assumed the editorship of the "Builder," a periodical devoted to the interests of architects. His remaining works are: "Facts and Fancies" (8vo., 1844); "Buildings and Monuments, Modern and Mediæval;" "History in Ruins: Letters on the History of Architecture" (12mo., 1853); "London Shadows" (1854).

GODWIN, PARKER, an American journalist and author, born in Paterson, N. J., Feb. 25, 1816. His father was an officer in the war of 1812, and his grandfather a soldier of the revolution. He was graduated at Princeton college in 1834, and having studied law in his native town, was admitted to practice at the bar in Kentucky, but did not pursue the profession. From 1837 to the close of 1853, with the exception of one year, he was the coadjutor of his father-in-law, William Cullen Bryant, in the editorial management of the New York "Evening Post." In Feb. 1843, he began the issue of the "Pathfinder," a weekly periodical of a literary and political character, which was conducted with ability, and attained a considerable circulation, though it was discontinued at the end of 3 months in consequence of the failure of the publisher. In 1852 Mr. Godwin visited Europe, travelling chiefly in England, the south of France, Italy, and Germany. While connected with the "Evening Post" he contributed to the "Democratic Review" a large number of articles. It is worthy of notice that in that journal Mr. Godwin first advocated the important reforms which were afterward carried out in the constitution and code of New York. Mr. Godwin's acquaintance with German literature was exemplified by his translation of Zschokke's tales and of the 1st part of Goethe's autobiography. Other works of his are: a "Popular View of the Doctrines of Charles Fourier" (New York, 1844); "Constructive Democracy;" "Vala, a Mythological Tale," founded on incidents in the life of Jenny Lind, and fancifully illustrated by his friends the artists Hicks, Rossiter, Whitley, and Wolcott (4to., 1851); and a "Hand Book of Universal Biography," published as one of the volumes of Putnam's "Home Cyclopedia" (12mo., 1851). To "Putnam's Monthly," of which he was for a considerable time an editor, he contributed many articles on literary and political topics. His political essays in this magazine were in 1856 published in a volume, and attracted great attention. Mr. Godwin has of late years been engaged in the preparation of an elaborate history of France. In politics he is a member of the republican party, to which he has given liberal service both as a speaker and writer. The only official station he

has occupied is that of deputy collector for the port of New York, which he filled under Mr. Polk's presidency. As a political essayist, he has attained a brilliant and enduring position among the writers of the time.
